8.1.2.11 STAR Project Devices	239
8.1.2.12 Usage Example	239
8.1.2.13 struct <code>rspi_config_t</code>	240
8.1.2.14 struct <code>rspi_controller_config_t</code>	241
8.1.2.15 struct <code>uart_channel_config_t</code>	241
8.1.3 Typedef Documentation	242
8.1.3.1 <code>adc_resolution_t</code>	242
8.1.4 Enumeration Type Documentation	242
8.1.4.1 <code>adc_channel_t</code>	242
8.1.4.2 Pin Mapping (RX72N 144-pin LFQFP, R5F572NNHxFB)	242
8.1.4.3 Input Specifications	243
8.1.4.4 Usage Example	243
8.1.4.5 <code>adc_unit_t</code>	244
8.1.4.6 Hardware Specifications	244
8.1.4.7 STAR Project Usage (144-pin LFQFP)	244
8.1.4.8 Type Safety Benefit	245
8.1.4.9 <code>riic_peripheral_limits_t</code>	245
8.1.4.10 <code>rspi_channel_t</code>	246
8.1.4.11 RX72N RSPI Channel Assignments (STAR Project)	246
8.1.4.12 <code>rspi_freq_constants_t</code>	247
8.1.4.13 <code>rspi_mode_t</code>	248
8.1.4.14 SPI Mode Definitions	248
8.1.4.15 STAR Project Usage	248
8.1.4.16 Clock Polarity (CPOL)	248
8.1.4.17 Clock Phase (CPHA)	248
8.1.4.18 Timing Diagrams	248
8.1.4.19 Selection Guidelines	249
8.1.4.20 Hardware Configuration	249
8.1.4.21 Usage Example	249
8.1.4.22 <code>uart_channel_t</code>	250
8.1.4.23 <code>uart_defaults_t</code>	251
8.1.5 Function Documentation	251
8.1.5.1 <code>adc_init()</code>	251
8.1.5.2 Initialization Behavior	252
8.1.5.3 <code>adc_read()</code>	254
8.1.5.4 Conversion Sequence	254
8.1.5.5 Output Value Ranges	254
8.1.5.6 <code>adc_read_voltage_mv()</code>	256
8.1.5.7 Voltage Calculation Formula	257
8.1.5.8 Example Calculations	257
8.1.5.9 <code>gpio_read()</code>	259
8.1.5.10 Algorithm	259
8.1.5.11 Performance	259

8.1.5.12 Register Operation	261
8.1.5.13 Input vs Output Reading	262
8.1.5.14 Voltage Thresholds (RX72N)	262
8.1.5.15 <code>gpio_set_input()</code>	264
8.1.5.16 Algorithm	265
8.1.5.17 Register Operations	266
8.1.5.18 Pull-up Configuration	266
8.1.5.19 Reading Input State	267
8.1.5.20 <code>gpio_set_output()</code>	269
8.1.5.21 Algorithm	270
8.1.5.22 Performance	270
8.1.5.23 Register Operations	272
8.1.5.24 Pin Reservation	272
8.1.5.25 Initial Output State	272
8.1.5.26 <code>gpio_toggle()</code>	274
8.1.5.27 Algorithm	275
8.1.5.28 Register Operation	276
8.1.5.29 Atomicity Warning	276
8.1.5.30 <code>gpio_write_high()</code>	278
8.1.5.31 Algorithm	279
8.1.5.32 Register Operation	280
8.1.5.33 Timing	280
8.1.5.34 <code>gpio_write_low()</code>	282
8.1.5.35 Algorithm	282
8.1.5.36 Register Operation	284
8.1.5.37 Open-Drain Mode	284
8.1.5.38 <code>riic_deinit_peripheral()</code>	286
8.1.5.39 <code>riic_init()</code>	289
8.1.5.40 Algorithm	289
8.1.5.41 Supported Frequencies	289
8.1.5.42 <code>riic_init_peripheral()</code>	292
8.1.5.43 Initialization Sequence	293
8.1.5.44 <code>riic_peripheral_read()</code>	295
8.1.5.45 Read Algorithm	297
8.1.5.46 <code>riic_peripheral_write()</code>	298
8.1.5.47 Write Algorithm	300
8.1.5.48 <code>riic_read()</code>	301
8.1.5.49 Transaction Sequence	301
8.1.5.50 Transaction Sequence	303
8.1.5.51 When to Use <code>riic_read()</code> vs <code>riic_write_read()</code>	303
8.1.5.52 Common Use Cases	303
8.1.5.53 <code>riic_write()</code>	306
8.1.5.54 Transaction Sequence	306

8.1.5.55 Transaction Sequence	308
8.1.5.56 Common Use Cases	308
8.1.5.57 Error Handling	309
8.1.5.58 riic_write_read()	311
8.1.5.59 Transaction Sequence	311
8.1.5.60 Transaction Sequence (Register Read)	313
8.1.5.61 Why Repeated START?	313
8.1.5.62 Common Use Cases	314
8.1.5.63 rspi_controller_deinit()	316
8.1.5.64 rspi_controller_set_cs()	319
8.1.5.65 rspi_controller_transfer_16bit()	323
8.1.5.66 rspi_deinit()	326
8.1.5.67 rspi_init_controller()	329
8.1.5.68 rspi_init_peripheral()	332
8.1.5.69 Algorithm	332
8.1.5.70 rspi_peripheral_read_available()	334
8.1.5.71 rspi_peripheral_transfer()	336
8.1.5.72 rspi_peripheral_write_ready()	339
8.1.5.73 timer_get_count()	341
8.1.5.74 timer_init()	345
8.1.5.75 Algorithm	346
8.1.5.76 timer_stop()	351
8.1.5.77 Algorithm	352
8.1.5.78 uart_clear_rx_errors()	354
8.1.5.79 uart_debug_init()	356
8.1.5.80 uart_debug_putc()	359
8.1.5.81 uart_debug_puthex()	361
8.1.5.82 uart_debug_putint()	364
8.1.5.83 uart_debug_puts()	366
8.1.5.84 uart_deinit_channel()	368
8.1.5.85 uart_getc_channel()	371

Chapter 5

Topic Documentation

5.1 RX72N S12AD Register Definitions

12-bit A/D Converter hardware register interface

Data Structures

- struct [rx_s12ad_regs_t](#)
S12ADFa Register Map for 12-bit A/D Converter.

Enumerations

- enum [rx_s12ad_addresses_t](#) : [uintptr_t](#) { [k_s12ad0_base_addr](#) = 0x00089000 , [k_s12ad1_base_addr](#) = 0x00089100 }
S12ADFa peripheral base addresses.
- enum [s12ad_offsets_t](#) : [uint8_t](#) {
[k_s12ad_offset_adcsr](#) = 0x00 , [k_s12ad_offset_adansa0](#) = 0x04 , [k_s12ad_offset_adads0](#) = 0x08 ,
[k_s12ad_offset_adadc](#) = 0x0C ,
[k_s12ad_offset_adcer](#) = 0x0E , [k_s12ad_offset_adstrgr](#) = 0x10 , [k_s12ad_offset_adansb0](#) = 0x14 ,
[k_s12ad_offset_adbldr](#) ,
[k_s12ad_offset_addrd](#) = 0x1E , [k_s12ad_offset_addr0](#) = 0x20 , [k_s12ad_offset_addr1](#) = 0x22 ,
[k_s12ad_offset_addr2](#) = 0x24 ,
[k_s12ad_offset_addr3](#) = 0x26 , [k_s12ad_offset_addr4](#) = 0x28 , [k_s12ad_offset_addr5](#) = 0x2A ,
[k_s12ad_offset_addr6](#) = 0x2C ,
[k_s12ad_offset_addr7](#) = 0x2E }
S12ADFa register offsets from base address.
- enum [s12ad_reserved_sizes_t](#) : [uint8_t](#) { [k_s12ad_reserved_02_03](#) = 2 , [k_s12ad_reserved_0d](#) = 1 , [k_s12ad_reserved_12_13](#) = 2 , [k_s12ad_reserved_16_1d](#) = 8 }
S12ADFa register reserved field sizes for structure padding.

Functions

- static volatile [rx_s12ad_regs_t](#) * [s12ad0](#) (void)
Get pointer to S12AD0 (Unit 0) registers.
- static volatile [rx_s12ad_regs_t](#) * [s12ad1](#) (void)
Get pointer to S12AD1 (Unit 1) registers.

5.1.1 Detailed Description

12-bit A/D Converter hardware register interface

Provides memory-mapped register access to the RX72N S12AD peripheral for motor current sensing applications. All register addresses and offsets are compile-time verified via static assertions.

Quick Start Example:

```
// Read motor 0 current from AN007 (P47)
volatile rx_s12ad_regs_t* adc = s12ad0();

// Enable channel 7 for single scan
adc->adansa0 = (1U « 7); // AN007 only

// Configure: single scan, software trigger
adc->adcsr = 0x0000;

// Start conversion
adc->adcsr |= 0x8000; // ADST bit

// Wait for completion
while (adc->adcsr & 0x8000) {}

// Read 12-bit result (right-aligned)
uint16_t raw_value = adc->addr7;

// Convert to voltage (3.3V reference)
static const float s_vref_volts = 3.3F;
static const float s_adc_full_scale_12bit = 4095.0F;
float voltage_v = (float)raw_value * s_vref_volts / s_adc_full_scale_12bit;
```

5.1.2 Data Structure Documentation

5.1.2.1 struct rx's12ad'regs't

S12ADFa Register Map for 12-bit A/D Converter.

Memory-mapped register structure for the S12AD peripheral. This structure provides direct hardware access to ADC control and data registers for motor current sensing and analog input measurement.

Memory Layout (Total: 48 bytes = 0x30):

Offset	Size	Field	Description
0x00	2	adcsr	Control/Status (mode, start, IRQ)
0x02	2	reserved	Reserved padding
0x04	2	adansa0	Channel select A (ch 0-15)
0x06	2	adansa1	Channel select A (ch 16-20, Unit1)
0x08	2	adads0	Addition mode (ch 0-15)
0x0A	2	adads1	Addition mode (ch 16-20, Unit1)
0x0C	1	adadc	Addition count (1, 2, 4, 16)
0x0D	1	reserved	Reserved padding
0x0E	2	adcer	Control extended (alignment)

Offset	Size	Field	Description
0x10	2	adstrgr	Trigger source select
0x12	2	reserved	Reserved padding
0x14	2	adansb0	Channel select B (group B scan)
0x16	8	reserved	Reserved (ADDBLDR at 0x84, not in struct)
0x1E	2	adrd	Self-diagnosis data
0x20	2	addr0	Result register AN0/AN100
0x22	2	addr1	Result register AN1/AN101
0x24	2	addr2	Result register AN2/AN102
0x26	2	addr3	Result register AN3/AN103
0x28	2	addr4	Result register AN4/AN104
0x2A	2	addr5	Result register AN5/AN105
0x2C	2	addr6	Result register AN6/AN106
0x2E	2	addr7	Result register AN7/AN107

Usage Example - Single Channel Conversion:

```
// Initialize ADC for motor 0 current sensing (AN007, P47)
volatile rx_s12ad_regs_t* adc = s12ad0();

// 1. Select channel AN007 for group A scan
adc->adansa0 = (1U << 7); // Bit 7 = AN007

// 2. Configure single scan mode, software trigger
adc->adcsr = 0x0000; // ADCS[1:0]=00 (single), TRGE=0 (software)

// 3. Set right-alignment (bits 11:0 contain result)
adc->adcr = 0x0000; // ADRFMT=0 (right-align)

// 4. Start conversion (set ADST bit)
adc->adcsr |= 0x8000;

// 5. Wait for conversion complete (ADST clears)
while (adc->adcsr & 0x8000) {
    // ~1 us per conversion
}

// 6. Read 12-bit result
uint16_t raw_count = adc->addr7 & 0xFFFF;

// 7. Convert to current (using DRV8263H-Q1 IPROPI current sensing)
// IPROPI mirror: 202 uA/A, sense resistor: 5100 ohm
// V_IPROPI = I_motor * 202e-6 * 5100 = I_motor * 1.0302
// so I_motor = V_IPROPI / 1.0302
static const float s_avcc_volts = 3.3F;
static const float s_adc_full_scale_divisor = 4095.0F; // 2^12 - 1 (12-bit full scale)
static const float s_ipropi_mirror = 202e-6F; // 202 uA/A current mirror ratio
static const float s_ipropi_sense_ohm = 5100.0F; // 5.1k sense resistor
static const float s_ipropi_divisor = 1.0302F; // = 202e-6 * 5100
float voltage = (float)raw_count * s_avcc_volts / s_adc_full_scale_divisor;
float current_amps = voltage / s_ipropi_divisor;
```

Usage Example - Continuous 4-Channel Scan:

```
volatile rx_s12ad_regs_t* adc = s12ad0();

// Enable channels AN004-AN007 (all 4 motor currents)
adc->adansa0 = 0x00F0; // Bits [7:4] = channels 4-7

// Configure continuous scan mode
adc->adcsr = 0x4000; // ADCS[1:0]=10 (continuous scan), bits[14:13]=10

// Start continuous conversion
adc->adcsr |= 0x8000;

// Read results any time (updated continuously)
```

```
uint16_t motor0_current = adc->addr7; // AN007 = M0
uint16_t motor1_current = adc->addr6; // AN006 = M1
uint16_t motor2_current = adc->addr5; // AN005 = M2
uint16_t motor3_current = adc->addr4; // AN004 = M3

// Stop conversion when done
adc->adcsr &= ~0x8000;
```

Note

This struct covers registers common to both S12AD0 and S12AD1. S12AD1 has additional registers (ADDR8-20, temp sensor, etc.) beyond offset 0x30 that are not included in this structure.

Warning

All registers are memory-mapped and must be accessed as volatile. Do not cache register values in local variables for repeated use.

Reserved fields must never be written. Reading returns undefined values.

Invariant

`sizeof(rx_s12ad_regs_t) == 0x30` (48 bytes)

All register offsets match RX72N Manual Ch56 Table 56.1

Data registers ADDR0-ADDR7 have 2-byte spacing

Collaboration diagram for `rx_s12ad_regs_t`:

Data Fields

volatile uint8_t	adadc	A/D Addition Count Select Register (ADADC) @ offset 0x0C. Sets the number of conversions to add/↵ average for oversampling. Valid Values: <table><tr><th>Value</th><th>Additio</th><th>Effect on Data</th><th>Time Multiplier</th></tr><tr><td>0x00</td><td>1x</td><td>No addition</td><td>1x</td></tr><tr><td>0x01</td><td>2x</td><td>Sum or average</td><td>2x</td></tr><tr><td>0x02</td><td>3x</td><td>Sum or average</td><td>3x</td></tr><tr><td>0x03</td><td>4x</td><td>Sum or average</td><td>4x</td></tr><tr><td>0x05</td><td>16x</td><td>Sum or average</td><td>16x</td></tr></table>	Value	Additio	Effect on Data	Time Multiplier	0x00	1x	No addition	1x	0x01	2x	Sum or average	2x	0x02	3x	Sum or average	3x	0x03	4x	Sum or average	4x	0x05	16x	Sum or average	16x
Value	Additio	Effect on Data	Time Multiplier																							
0x00	1x	No addition	1x																							
0x01	2x	Sum or average	2x																							
0x02	3x	Sum or average	3x																							
0x03	4x	Sum or average	4x																							
0x05	16x	Sum or average	16x																							
volatile uint16_t	adads0	A/D Addition Mode Select Register 0 (ADADS0) @ offset 0x08. Selects channels 0-15 for addition/↵ averaging mode. When enabled, multiple conversions are accumulated or averaged per the ADADC setting. Oversampling Benefit: • 4x averaging: Reduces noise by ~6 dB (factor of 2) • 16x averaging: Reduces noise by ~12 dB (factor of 4)																								
volatile uint16_t	adads1	A/D Addition Mode Select Register 1 (ADADS1) @ offset 0x0A. Selects channels 16-20 for addition mode (S12AD1 only).																								

volatile uint16_t	adansa0	A/D Channel Select Register A0 (ADANSA0) @ offset 0x04. Selects channels 0-15 for Group A scan. Each bit enables the corresponding analog input channel. <table><tr><th>Bit</th><th>Channel</th><th>Pin</th><th>Usage</th></tr><tr><td>0-3</td><td>AN000-3</td><td>P40-43</td><td>Available</td></tr><tr><td>4</td><td>AN004</td><td>P44</td><td>M3 current</td></tr><tr><td>5</td><td>AN005</td><td>P45</td><td>M2 current</td></tr><tr><td>6</td><td>AN006</td><td>P46</td><td>M1 current</td></tr><tr><td>7</td><td>AN007</td><td>P47</td><td>M0 current</td></tr></table> Channel Mapping (S12AD0, 144-pin LFP): Example: Select motor 0 and 1 current channels <pre>adc->adansa0 = 0x00C0; // Enable AN007 (M0), AN006 (M1)</pre>	Bit	Channel	Pin	Usage	0-3	AN000-3	P40-43	Available	4	AN004	P44	M3 current	5	AN005	P45	M2 current	6	AN006	P46	M1 current	7	AN007	P47	M0 current
Bit	Channel	Pin	Usage																							
0-3	AN000-3	P40-43	Available																							
4	AN004	P44	M3 current																							
5	AN005	P45	M2 current																							
6	AN006	P46	M1 current																							
7	AN007	P47	M0 current																							
volatile uint16_t	adansa1	A/D Channel Select Register A1 (ADANSA1) @ offset 0x06. Selects channels 16-20 for Group A scan (S12AD1 only). For S12AD0, this register exists but bits [7:0] are reserved. Note Only valid for S12AD1. S12AD0 has only 8 channels (0-7).																								
volatile uint16_t	adansb0	A/D Channel Select Register B0 (ADANSB0) @ offset 0x14. Selects channels for Group B scan (dual-group scanning mode). Group B runs in parallel with Group A for interleaved sampling.																								

volatile uint16_t	adcer	A/D Control Extended Register (AD-CER) @ offset 0x0E. Configures data alignment and self-diagnosis mode. Key Bits: • Bit 15 (ADRFMT): 0=right-align (bits [11:0]), 1=left-align (bits [15:4]) • Bit 5 (ACE): Auto-clear enable for data registers Alignment Example: • Right-align: Result in bits ↵ [11:0], bits [15:12] = 0 • Left-align: Result in bits [15:↵ 4], bits [3:0] = 0
-------------------	-------	--

volatile uint16_t	adcsr	A/D Control/Status Register (ADCSR) @ offset 0x00. Controls conversion mode, trigger source, and interrupt enable. <table><tr><th>Bits</th><th>Name</th><th>R/W</th><th>Description</th></tr><tr><td>[15]</td><td>ADST</td><td>R/W</td><td>Conversion start (1=start/↔running)</td></tr><tr><td>[14:↔13]</td><td>ADCS</td><td>R/W</td><td>Scan mode (00=single, 01=group, 10=continuous)</td></tr><tr><td>[12]</td><td>ADIE</td><td>R/W</td><td>Scan end interrupt enable</td></tr><tr><td>[9]</td><td>TRGE</td><td>R/W</td><td>Trigger start enable (0=software only, 1=sync/↔async trigger)</td></tr><tr><td>[8]</td><td>EXTRG</td><td>R/W</td><td>Trigger select (0=synchronous, 1=asynchronous)</td></tr><tr><td>[7]</td><td>DBLE</td><td>R/W</td><td>Double trigger mode select</td></tr><tr><td>[6]</td><td>GBADIER</td><td>R/W</td><td>Group B scan end interrupt enable</td></tr></table> Bit Field Description: Common Configurations:	Bits	Name	R/W	Description	[15]	ADST	R/W	Conversion start (1=start/↔running)	[14:↔13]	ADCS	R/W	Scan mode (00=single, 01=group, 10=continuous)	[12]	ADIE	R/W	Scan end interrupt enable	[9]	TRGE	R/W	Trigger start enable (0=software only, 1=sync/↔async trigger)	[8]	EXTRG	R/W	Trigger select (0=synchronous, 1=asynchronous)	[7]	DBLE	R/W	Double trigger mode select	[6]	GBADIER	R/W	Group B scan end interrupt enable
Bits	Name	R/W	Description

volatile uint16_t	addr0	A/D Data Register 0 (ADDR0) @ offset 0x20. 12-bit conversion result for channel AN000 (Unit 0) or AN100 (Unit 1). Data Format (ADCER.ADRFMT=0, right-aligned): • Bits [11:0]: 12-bit result (0-4095) • Bits [15:12]: Always 0 Conversion Formula: $V_{in} = \frac{ADC_{result} \times V_{ref}}{4095}$ where Vref = 3.3V (AVCC0)
volatile uint16_t	addr1	A/D Data Register 1 @ 0x22: AN001/↔ AN101
volatile uint16_t	addr2	A/D Data Register 2 @ 0x24: AN002/↔ AN102
volatile uint16_t	addr3	A/D Data Register 3 @ 0x26: AN003/↔ AN103
volatile uint16_t	addr4	A/D Data Register 4 @ 0x28: AN004/↔ AN104 (Motor 3 current)
volatile uint16_t	addr5	A/D Data Register 5 @ 0x2A: AN005/↔ AN105 (Motor 2 current)
volatile uint16_t	addr6	A/D Data Register 6 @ 0x2C: AN006/↔ AN106 (Motor 1 current)
volatile uint16_t	addr7	A/D Data Register 7 @ 0x2E: AN007/↔ AN107 (Motor 0 current)
volatile uint16_t	adrd	A/D Self-Diagnosis Data Register (ADRD) @ offset 0x1E. Contains result of self-diagnosis conversion when ADCER.DIAGM = 1. Used for ADC calibration and health monitoring.

volatile uint16_t	adstrgr	A/D Start Trigger Select Register (ADSTRGR) @ offset 0x10. Selects the trigger source for starting A/D conversion when hardware triggering is enabled (ADCSR.TRGE = 1). Trigger Sources (TRSA[5:0] at bits [13:8]; TRSB[5:0] at bits [5:0]): <table> <tr> <th>Value</th><th>Source</th><th>Use Case</th></tr> <tr> <td>0x00</td><td>Software (ADST)</td><td>Polled conversion</td></tr> <tr> <td>0x01</td><td>MTU0 TGIA</td><td>Motor PWM sync</td></tr> <tr> <td>0x02</td><td>MTU0 TGIB</td><td>Motor PWM sync</td></tr> <tr> <td>0x09</td><td>MTU4 TAD-CORA</td><td>MTU4 PWM sync</td></tr> </table>	Value	Source	Use Case	0x00	Software (ADST)	Polled conversion	0x01	MTU0 TGIA	Motor PWM sync	0x02	MTU0 TGIB	Motor PWM sync	0x09	MTU4 TAD-CORA	MTU4 PWM sync

5.1.3 Enumeration Type Documentation

5.1.3.1 rx's12ad'addresses't

```
enum rx_s12ad_addresses_t : uintptr_t
```

S12ADFa peripheral base addresses.

Hardware base addresses for the two S12AD units on RX72N. Each unit occupies 256 bytes (0x100) of address space in the peripheral area.

Per RX72N Manual Ch56 and Ch04 Memory Map:

- S12AD0: 0x00089000 (Unit 0, 8 high-speed channels)
- S12AD1: 0x00089100 (Unit 1, 21 channels + temperature sensor)

Address Space Layout:

Address Range	Description
0x00089000 - 0x000890FF	S12AD0 registers (Unit 0)
0x00089100 - 0x000891FF	S12AD1 registers (Unit 1)

Unit Selection Guidelines:

- Use S12AD0 for motor current sensing (lower latency, 8 channels)
- Use S12AD1 for temperature monitoring (has internal sensor)

Invariant

Base addresses are 256-byte aligned (bits [7:0] = 0)

Unit spacing is exactly 0x100 bytes

[s12ad1\(\)](#) Accessor function for Unit 1

Enumerator

k_s12ad0_base_addr	S12AD Unit 0 base address. 8-channel high-speed ADC optimized for motor current sensing. Channels AN000-AN007 mapped to ports P40-P47. Usage: Motor current sensing (all 4 motors) Throughput: Up to 1 MSPS in continuous scan mode
k_s12ad1_base_addr	S12AD Unit 1 base address. 21-channel ADC with additional features including temperature sensor and internal voltage reference channels. Channels AN100-AN120 mapped to various ports. Usage: Temperature monitoring, analog sensing Special Channels: Temperature sensor (AN127), Ref voltage (AN128)

```

5.1.3.2 s12ad_offsets_t

```
enum s12ad_offsets_t : uint8_t
```

S12ADFa register offsets from base address.

Register byte offsets for accessing S12AD peripheral registers. All offsets verified against RX72N Manual Ch56, section 56.2.

Register Map Overview:

Offset	Register	Size	Description
0x00	ADCSR	16	Control/Status (start, mode)
0x04	ADANSA0	16	Channel select Group A (0-15)
0x08	ADADS0	16	Addition mode select
0x0C	ADADC	8	Addition count (1, 2, 4, 16)
0x0E	ADCER	16	Control extended (alignment)
0x10	ADSTRGR	16	Trigger source select
0x14	ADANSB0	16	Channel select Group B
0x84	ADDBLDR	16	Double trigger data (not in struct; accessed directly)
0x1E	ADRD	16	Self-diagnosis data
0x20	ADDR0	16	Conversion result channel 0
...	...	...	(2-byte spacing per channel)
0x2E	ADDR7	16	Conversion result channel 7

Note

Offsets are 8-bit values (max 255), sufficient for S12AD register space

Invariant

Data registers ADDR0-ADDR7 are contiguous with 2-byte spacing

All 16-bit registers are halfword-aligned (even addresses)

Enumerator

k_s12ad_offset_adcsr	A/D Control Status: start, mode, interrupt control

00260 } s12ad_offsets_t;

```

5.1.3.3 s12ad_reserved_sizes_t

```
enum s12ad_reserved_sizes_t : uint8_t
```

S12ADFa register reserved field sizes for structure padding.

Defines byte sizes for reserved regions in the S12AD register map. These ensure proper alignment and offset matching between the C structure and actual hardware register locations.

Warning

Do not modify these values - they are derived from the RX72N hardware register layout specification.

Note

Reserved bytes must be declared as `uint8_t` arrays, not accessed

Enumerator

<code>k_s12ad_reserved_02_03</code>	Padding after ADCSR (16-bit) to ADANSA0 (32-bit aligned)
<code>k_s12ad_reserved_0d</code>	Padding after ADADC (8-bit) to ADCER (16-bit aligned)
<code>k_s12ad_reserved_12_13</code>	Padding after ADSTRGR to ADANSB0
<code>k_s12ad_reserved_16_1d</code>	Padding after ADANSB0 to ADRD (ADDBLDR at 0x84, not in struct)

Definition at line 276 of file `rx72n_adc_regs.h`.

```

00276     : uint8_t {
00277   k_s12ad_reserved_02_03 = 2, /**< Padding after ADCSR (16-bit) to ADANSA0 (32-bit aligned) */
00278   k_s12ad_reserved_0d   = 1, /**< Padding after ADADC (8-bit) to ADCER (16-bit aligned) */
00279   k_s12ad_reserved_12_13 = 2, /**< Padding after ADSTRGR to ADANSB0 */
00280   k_s12ad_reserved_16_1d = 8, /**< Padding after ADANSB0 to ADRD (ADDBLDR at 0x84, not in struct) */
00281 } s12ad_reserved_sizes_t;

```

5.1.4 Function Documentation

5.1.4.1 `s12ad0()`

```

volatile rx_s12ad_regs_t * s12ad0 (
    void ) [inline], [static]

```

Get pointer to S12AD0 (Unit 0) registers.

Returns a volatile pointer to the S12AD Unit 0 register structure, enabling direct hardware register access for ADC operations. Unit 0 is optimized for motor current sensing with 8 high-speed channels.

Returns

Volatile pointer to S12AD0 register structure at 0x00089000

Precondition

Module stop state must be released (`MSTPCRA.MSTPA17 = 0`)
 AVCC0 and AVSS0 power supplies must be stable

Postcondition

Pointer is immediately usable for register access
 No hardware state is modified by this function

Note

Thread Safety: Function is reentrant and thread-safe (returns constant address)

Performance: Zero overhead - compiles to single load instruction

Example - Motor Current Sensing (144-pin LFQFP):

```
// Read all 4 motor currents (AN004-AN007 on P44-P47)
volatile rx_s12ad_regs_t* adc = s12ad0();

// Configure for 4-channel scan
adc->adansa0 = 0x00F0; // AN004-AN007
adc->adcsr = 0x0000; // Single scan, software trigger
adc->adcer = 0x0000; // Right-aligned data

// Perform conversion
adc->adcsr |= 0x8000; // Start
while (adc->adcsr & 0x8000) {} // Wait (~4 us for 4 channels)

// Read currents (M0=AN007, M1=AN006, M2=AN005, M3=AN004)
uint16_t motor_currents[4] = {
    adc->addr7, adc->addr6, adc->addr5, adc->addr4
};
```

[rx_s12ad_regs_t](#) Register structure definition

Definition at line 622 of file [rx72n_adc_regs.h](#).

```
00623 {
00624     return (volatile rx_s12ad_regs_t*)k_s12ad0_base_addr;
00625 }
```

References [k_s12ad0_base_addr](#).

Referenced by [internal_get_adc_base\(\)](#).

Here is the caller graph for this function:

5.1.4.2 s12ad1()

```
volatile rx_s12ad_regs_t * s12ad1 (
    void ) [inline], [static]
```

Get pointer to S12AD1 (Unit 1) registers.

Returns a volatile pointer to the S12AD Unit 1 register structure. Unit 1 provides 21 analog channels plus temperature sensor and internal voltage reference for calibration and monitoring.

Returns

Volatile pointer to S12AD1 register structure at 0x00089100

Precondition

Module stop state must be released (MSTPCRA.MSTPA16 = 0)
 AVCC0 and AVSS0 power supplies must be stable

Postcondition

Pointer is immediately usable for register access
 No hardware state is modified by this function

Note

Thread Safety: Function is reentrant and thread-safe
 Performance: Zero overhead - compiles to single load instruction

Warning

The [rx_s12ad_regs_t](#) structure only covers registers up to ADDR7. S12AD1 has additional registers (ADDR8-20, temperature sensor, internal reference) at higher offsets that require direct access.

Example - Temperature Sensor Reading:

```
volatile rx_s12ad_regs_t* adc = s12ad1();

// Enable internal temperature sensor (AN127)
// Note: Requires accessing registers beyond rx_s12ad_regs_t
// See RX72N Manual Ch56 for temperature sensor configuration
```

CMT register layout constants used for compile-time verification.
- enum [rx_cmt_cmstr0_bits_t](#) : `uint8_t` { `k_rx72n_cmstr0_cmt0_enable = 0x01` , `k_rx72n_cmstr0_cmt1_enable = 0x02` }
CMSTR0 register bit definitions (CMT Unit 0 start control).
- enum [rx_cmt_cmstr1_bits_t](#) : `uint8_t` { `k_rx72n_cmstr1_cmt2_enable = 0x01` , `k_rx72n_cmstr1_cmt3_enable = 0x02` }
CMSTR1 register bit definitions (CMT Unit 1 start control).

Functions

- static volatile [rx_cmt_channel_regs_t](#) * `cmt0` (void)
Get pointer to CMT0 registers.
- static volatile [rx_cmt_channel_regs_t](#) * `cmt1` (void)
Get pointer to CMT1 registers.
- static volatile [rx_cmt_channel_regs_t](#) * `cmt2` (void)
Get pointer to CMT2 registers.
- static volatile [rx_cmt_channel_regs_t](#) * `cmt3` (void)
Get pointer to CMT3 registers.
- static volatile [rx_cmt_control_regs_t](#) * `cmt_ctrl` (void)
Get pointer to CMT control registers (CMSTR0).
- static volatile [rx_cmt_control_regs_t](#) * `cmt_ctrl1` (void)
Get pointer to CMT Unit 1 control register (CMSTR1).

5.2.1 Detailed Description

Compare Match Timer (CMT) hardware register interface.

5.2.2 Data Structure Documentation

5.2.2.1 struct rx_cmt_channel_regs_t

CMT Channel Register Map (6 bytes per channel).

Compare Match Timer (CMT) channel registers for periodic interrupt generation. Each channel is a 16-bit up-counter that generates an interrupt when CMCNT matches CMCOR, then resets to 0 and continues counting.

Register Layout (6 bytes)

* Offset	* Size	* Register	* Description
* -----+-----+-----+-----			
* 0x00	* 2	* CMCR	* Control: clock div, IRQ enable
* 0x02	* 2	* CMCNT	* Counter: current count value
* 0x04	* 2	* CMCOR	* Compare: match value (period)
*			

CMCR Register Bit Layout (RX72N Manual Ch31, p.1583)

* Bit	* Name	* Description
* -----+-----+-----		
* 15-8	* -	* Reserved
* 7	* -	* Reserved (write value should be 1)
* 6	* CMIE	* Compare Match Interrupt Enable
* 5-2	* -	* Reserved
* 1-0	* CKS	* Clock Select (00=PCLK/8, 01=/32, 10=/128, 11=/512)
*		

Timer Operation

1. Configure CMCR with clock divider and interrupt enable
2. Set CMCOR to desired period value
3. Clear CMCNT to 0
4. Enable timer via CMSTRn register
5. Counter increments at PCLKB/DIV rate
6. When CMCNT == CMCOR, interrupt fires and CMCNT resets to 0

Invariant

CMCNT ≤ CMCOR during normal operation

Collaboration diagram for [rx_cmt_channel_regs_t](#):

Data Fields

volatile uint16_t	cmcnt	Compare Match Timer Counter Register. 16-bit up-counter incremented by selected clock. Cleared to 0 on compare match and when timer is stopped. - Read: Current counter value - Write: Set counter value (typically write 0 before starting)																
volatile uint16_t	cmcor	Compare Match Timer Constant Register. Compare match value. When CMCNT equals this value, an interrupt is generated (if CMIE=1) and CMCNT resets to 0. Period calculation: $T = \frac{(CMCOR+1) \times DIV}{f_{PCLKB}}$ <table><tr><th>CMCOR Value</th><th>Divider</th><th>Period @ 60MHz PCLKB</th></tr><tr><td>18749</td><td>/32</td><td>10 ms (100 Hz)</td></tr><tr><td>1874</td><td>/32</td><td>1 ms (1000 Hz)</td></tr><tr><td>7499</td><td>$\frac{PCLKB}{8}$</td><td>1 ms (1000 Hz)</td></tr></table> Note: PCLKB/8 cannot reach 100 Hz (requires CMCOR=74999 > uint16_t max 65535).	CMCOR Value	Divider	Period @ 60MHz PCLKB	18749	/32	10 ms (100 Hz)	1874	/32	1 ms (1000 Hz)	7499	$\frac{PCLKB}{8}$	1 ms (1000 Hz)				
CMCOR Value	Divider	Period @ 60MHz PCLKB																
18749	/32	10 ms (100 Hz)																
1874	/32	1 ms (1000 Hz)																
7499	$\frac{PCLKB}{8}$	1 ms (1000 Hz)																
volatile uint16_t	cmcr	Compare Match Timer Control Register. Controls clock source divider and interrupt enable. <table><tr><th>Bits</th><th>Name</th><th>R/W</th><th>Description</th></tr><tr><td>7</td><td>-</td><td>R/W</td><td>Reserved; write value should be 1 (manual p.1583)</td></tr><tr><td>6</td><td>CMIE</td><td>R/W</td><td>1 = Enable compare match interrupt</td></tr><tr><td>1-0</td><td>CKS</td><td>R/W</td><td>Clock select: 00=/8, 01=/32, 10=/128, 11=/512</td></tr></table>	Bits	Name	R/W	Description	7	-	R/W	Reserved; write value should be 1 (manual p.1583)	6	CMIE	R/W	1 = Enable compare match interrupt	1-0	CKS	R/W	Clock select: 00=/8, 01=/32, 10=/128, 11=/512
Bits	Name	R/W	Description															
7	-	R/W	Reserved; write value should be 1 (manual p.1583)															
6	CMIE	R/W	1 = Enable compare match interrupt															
1-0	CKS	R/W	Clock select: 00=/8, 01=/32, 10=/128, 11=/512															

5.2.2.2 struct rx_cmt_control_regs_t

CMT Start/Stop Control Register Map.

Controls starting and stopping of CMT channels. Each unit has a separate start register controlling two channels.

Memory Layout

```
*  Address   | Register | Controls
*  -----+-----+-----
*  0x00088000 | CMSTR0   | CMT0, CMT1
*  0x00088010 | CMSTR1   | CMT2, CMT3
*
```

Note

CMSTR0 and CMSTR1 are NOT contiguous! CMSTR1 is at +0x10 from CMSTR0. This struct is only for documentation; use [cmt_ctrl\(\)](#) for CMSTR0.

Usage Example

```
// Start CMT0
cmt_ctrl()->cmstr0 |= k_rx72n_cmstr0_cmt0_enable;

// Stop CMT0
cmt_ctrl()->cmstr0 &= ~k_rx72n_cmstr0_cmt0_enable;
```

Definition at line 335 of file [rx72n_cmt_regs.h](#).

Collaboration diagram for rx_cmt_control_regs_t:

Data Fields

volatile uint16_t	cmstr0	Compare Match Timer Start Register 0. Controls CMT0 and CMT1 operation. • Bit 0 (STR0): 1 = Start CMT0, 0 = Stop CMT0 • Bit 1 (STR1): 1 = Start CMT1, 0 = Stop CMT1
-------------------	--------	---

volatile uint16_t	cmstr1	Compare Match Timer Start Register 1. Controls CMT2 and CMT3 operation. • Bit 0 (STR2): 1 = Start CMT2, 0 = Stop CMT2 • Bit 1 (STR3): 1 = Start CMT3, 0 = Stop CMT3 Warning This field is NOT at the expected offset! CMSTR1 is at 0x00088010, not 0x00088002. Access via separate function.
-------------------	--------	--

5.2.3 Enumeration Type Documentation

5.2.3.1 rx'cmt'addresses't

enum `rx_cmt_addresses_t` : `uintptr_t`

CMT base addresses (verified against RX72N Hardware Manual Ch31).

The RX72N has 4 CMT channels organized into 2 units:

- Unit 0: CMT0 and CMT1 (controlled by CMSTR0)
- Unit 1: CMT2 and CMT3 (controlled by CMSTR1)

Memory Layout

* Address	Content
* -----+	
* 0x00088000	CMSTR0 (Unit 0 start)
* 0x00088002	CMT0 registers (6 bytes)
* 0x00088008	CMT1 registers (6 bytes)
* 0x00088010	CMSTR1 (Unit 1 start)
* 0x00088012	CMT2 registers (6 bytes)
* 0x00088018	CMT3 registers (6 bytes)
*	

Note

CMSTR registers are at base, channel registers follow at +2 offset.

Enumerator

k_cmt_ctrl_base_addr	CMSTR0 base: Unit 0 start register (CMT0/CMT1)
k_cmt1_ctrl_base_addr	CMSTR1 base: Unit 1 start register (CMT2/CMT3)
k_cmt0_base_addr	CMT0 registers (CMCR, CMCNT, CMCOR)
k_cmt1_base_addr	CMT1 registers (CMCR, CMCNT, CMCOR)
k_cmt2_base_addr	CMT2 registers (CMCR, CMCNT, CMCOR)
k_cmt3_base_addr	CMT3 registers (CMCR, CMCNT, CMCOR)

Definition at line 187 of file `rx72n_cmt_regs.h`.

```

00187         : uintptr_t {
00188     k_cmt_ctrl_base_addr = 0x00088000, /**< CMSTR0 base: Unit 0 start register (CMT0/CMT1) */
00189     k_cmt1_ctrl_base_addr = 0x00088010, /**< CMSTR1 base: Unit 1 start register (CMT2/CMT3) */
00190     k_cmt0_base_addr      = 0x00088002, /**< CMT0 registers (CMCR, CMCNT, CMCOR) */
00191     k_cmt1_base_addr      = 0x00088008, /**< CMT1 registers (CMCR, CMCNT, CMCOR) */
00192     k_cmt2_base_addr      = 0x00088012, /**< CMT2 registers (CMCR, CMCNT, CMCOR) */
00193     k_cmt3_base_addr      = 0x00088018, /**< CMT3 registers (CMCR, CMCNT, CMCOR) */
00194 } rx_cmt_addresses_t;

```

5.2.3.2 rx_cmt_cmstr0_bits_t

```
enum rx_cmt_cmstr0_bits_t : uint8_t
```

CMSTR0 register bit definitions (CMT Unit 0 start control).

Bit field definitions for Compare Match Timer Start Register 0. Controls starting and stopping of CMT0 and CMT1 channels.

Register Layout (16-bit, only bits 0-1 used)

```
* Bit | Name | Description
* ----+-----+-----
* 0 | STR0 | 1 = Start CMT0, 0 = Stop CMT0
* 1 | STR1 | 1 = Start CMT1, 0 = Stop CMT1
* 2-15| - | Reserved (write 0)
*
```

Enumerator

k_rx72n_cmstr0_cmt0_enable	Bit 0: Start/stop CMT0 counter
k_rx72n_cmstr0_cmt1_enable	Bit 1: Start/stop CMT1 counter

Definition at line 373 of file [rx72n_cmt_regs.h](#).

```
00373 : uint8_t {
00374 k_rx72n_cmstr0_cmt0_enable = 0x01, /**< Bit 0: Start/stop CMT0 counter */
00375 k_rx72n_cmstr0_cmt1_enable = 0x02, /**< Bit 1: Start/stop CMT1 counter */
00376 } rx_cmt_cmstr0_bits_t;
```

5.2.3.3 rx_cmt_cmstr1_bits_t

```
enum rx_cmt_cmstr1_bits_t : uint8_t
```

CMSTR1 register bit definitions (CMT Unit 1 start control).

Bit field definitions for Compare Match Timer Start Register 1. Controls starting and stopping of CMT2 and CMT3 channels.

Note

CMSTR1 is at address 0x00088010, which is 16 bytes after CMSTR0.

Register Layout (16-bit, only bits 0-1 used)

```
* Bit | Name | Description
* ----+-----+-----
* 0 | STR2 | 1 = Start CMT2, 0 = Stop CMT2
* 1 | STR3 | 1 = Start CMT3, 0 = Stop CMT3
* 2-15| - | Reserved (write 0)
*
```

Enumerator

k_rx72n_cmstr1_cmt2_enable	Bit 0: Start/stop CMT2 counter
k_rx72n_cmstr1_cmt3_enable	Bit 1: Start/stop CMT3 counter

Definition at line 397 of file [rx72n_cmt_regs.h](#).

```
00397      : uint8_t {
00398  k_rx72n_cmstr1_cmt2_enable = 0x01, /**< Bit 0: Start/stop CMT2 counter */
00399  k_rx72n_cmstr1_cmt3_enable = 0x02, /**< Bit 1: Start/stop CMT3 counter */
00400 } rx_cmt_cmstr1_bits_t;
```

5.2.3.4 rx_cmt_layout_t

```
enum rx_cmt_layout_t : uint8_t
```

CMT register layout constants used for compile-time verification.

Physical byte sizes and register offsets for CMT structures. Used exclusively in static_assert expressions so no magic numbers appear in code.

00217 } rx_cmt_layout_t;
```

5.2.4 Function Documentation

5.2.4.1 cmt0()

```
volatile rx_cmt_channel_regs_t * cmt0 (
    void )    [inline], [static]
```

Get pointer to CMT0 registers.

Returns a volatile pointer to CMT channel 0 registers at address 0x00088002. CMT0 is typically used for the ThreadX system tick (100 Hz).

Returns

Volatile pointer to CMT0 register structure

Example

```
// Configure CMT0 for 100 Hz interrupt with PCLKB/32 divider
cmt0()->cmcr = 0x00C1; // CKS=01 (PCLKB/32), CMIE=1, bit7=1(rsvd)
cmt0()->cmcor = 18749; // 60MHz/32/100Hz - 1
cmt0()->cmcnt = 0;    // Clear counter
```

5.2.4.2 `cmt1()`

```
volatile rx_cmt_channel_regs_t * cmt1 (
    void ) [inline], [static]
```

Get pointer to CMT1 registers.

Returns a volatile pointer to CMT channel 1 registers at address 0x00088008. CMT1 is available for general-purpose timing.

Returns

Volatile pointer to CMT1 register structure

Definition at line 445 of file `rx72n_cmt_regs.h`.

```
00446 {
00447     return (volatile rx_cmt_channel_regs_t*)k_cmt1_base_addr;
00448 }
```

References `k_cmt1_base_addr`.

Referenced by `internal_get_cmt_base()`.

Here is the caller graph for this function:

5.2.4.3 `cmt2()`

```
volatile rx_cmt_channel_regs_t * cmt2 (
    void ) [inline], [static]
```

Get pointer to CMT2 registers.

Returns a volatile pointer to CMT channel 2 registers at address 0x00088012. CMT2 is part of Unit 1 (controlled by CMSTR1).

Returns

Volatile pointer to CMT2 register structure

Definition at line 459 of file `rx72n_cmt_regs.h`.

```
00460 {
00461     return (volatile rx_cmt_channel_regs_t*)k_cmt2_base_addr;
00462 }
```

References `k_cmt2_base_addr`.

Referenced by `internal_get_cmt_base()`.

Here is the caller graph for this function:

5.2.4.4 cmt3()

```
volatile rx_cmt_channel_regs_t * cmt3 (
    void ) [inline], [static]
```

Get pointer to CMT3 registers.

Returns a volatile pointer to CMT channel 3 registers at address 0x00088018. CMT3 is part of Unit 1 (controlled by CMSTR1).

Returns

Volatile pointer to CMT3 register structure

Definition at line 473 of file rx72n_cmt_regs.h.

```
00474 {
00475     return (volatile rx_cmt_channel_regs_t*)k_cmt3_base_addr;
00476 }
```

References [k_cmt3_base_addr](#).

Referenced by [internal_get_cmt_base\(\)](#).

Here is the caller graph for this function:

5.2.4.5 cmt_ctrl()

```
volatile rx_cmt_control_regs_t * cmt_ctrl (
    void ) [inline], [static]
```

Get pointer to CMT control registers (CMSTR0).

Returns a volatile pointer to CMT control register structure at address 0x00088000. Provides access to CMSTR0 for starting/stopping CMT0 and CMT1.

Warning

CMSTR1 (for CMT2/3) is at 0x00088010, not adjacent to CMSTR0. The [rx_cmt_control_regs_t](#) struct has incorrect cmstr1 offset. For CMSTR1 access, use: `*(volatile uint16_t*)0x00088010`

Returns

Volatile pointer to CMT control register structure

Example

```
// Start CMT0
cmt_ctrl()->cmstr0 |= k_rx72n_cmstr0_cmt0_enable;

// Stop CMT0 and CMT1
cmt_ctrl()->cmstr0 = 0;
```

Definition at line 500 of file [rx72n_cmt_regs.h](#).

```
00501 {
00502     return (volatile rx_cmt_control_regs_t*)k_cmt_ctrl_base_addr;
00503 }
```

References [k_cmt_ctrl_base_addr](#).

Referenced by [rx_cmt_start\(\)](#), [rx_cmt_stop\(\)](#), [timer_init\(\)](#), and [timer_stop\(\)](#).

Here is the caller graph for this function:

5.2.4.6 `cmt_ctrl()`

```
volatile rx_cmt_control_regs_t * cmt_ctrl (
    void ) [inline], [static]
```

Get pointer to CMT Unit 1 control register (CMSTR1).

Returns a volatile pointer to CMSTR1 at address 0x00088010. CMSTR1 is NOT contiguous with CMSTR0 – it is 0x10 bytes after CMSTR0. This accessor provides correct access to CMSTR1 for starting/↵ stopping CMT2 and CMT3.

Warning

Do NOT use `cmt_ctrl()->cmstr1` to access CMSTR1 – the struct field `cmstr1` sits at offset +2 from CMSTR0 (address 0x00088002), which is CMT0.CMCR, not CMSTR1.

Returns

Volatile pointer to CMT Unit 1 control register structure

Example

```
// Start CMT2
cmt_ctrl1()->cmstr0 |= k_rx72n_cmstr1_cmt2_enable;

// Stop CMT3
cmt_ctrl1()->cmstr0 &= ~k_rx72n_cmstr1_cmt3_enable;
```

5.2.5 CMT Static Assertions

Compile-time verification of CMT register layout.

Collaboration diagram for CMT Static Assertions:

Compile-time verification of CMT register layout.

These static assertions are verified at compile time to ensure the C structure definitions match the actual hardware register layout. A failed assertion indicates a bug in the register definitions that must be fixed before the code can compile.

5.3 RX72N GPTW Register Definitions

General PWM Timer hardware register interface.

Data Structures

- struct `rx_gptw_channel_regs_t`
GPTW Channel Register Map for 32-bit PWM generation.
- struct `rx_gptw_common_regs_t`
GPTW Common Register Map.

Enumerations

- enum `gptw_padding_sizes_t` : `uint8_t` { `k_gptw_ch_reserved_count` = 6U }
- enum `gptw_addresses_t` : `uintptr_t` {
`k_gptw_channel_offset` = 0x100 , `k_gptw0_base_addr` = 0x000C2000 , `k_gptw1_base_addr` = 0x000C2100 , `k_gptw2_base_addr` = 0x000C2200 ,
`k_gptw3_base_addr` = 0x000C2300 , `k_gptw_common_base_addr` }
GPTW hardware addresses (verified against RX72N Hardware Manual).
- enum `gptw_gtwp_bits_t` : `uint16_t` {
`k_gptw_gtwp_wp0` = (1 << 0) , `k_gptw_gtwp_wp1` = (1 << 1) , `k_gptw_gtwp_wp2` = (1 << 2) , `k_gptw_gtwp_wp3` = (1 << 3) ,

## Functions

- static volatile `rx_gptw_channel_regs_t` \* `gptw0` (void)  
GPTW register inline accessor functions.
- static volatile `rx_gptw_channel_regs_t` \* `gptw1` (void)
- static volatile `rx_gptw_channel_regs_t` \* `gptw2` (void)
- static volatile `rx_gptw_channel_regs_t` \* `gptw3` (void)
- static volatile `rx_gptw_common_regs_t` \* `gptw_common` (void)  
GPTW common register accessor.

### 5.3.1 Detailed Description

General PWM Timer hardware register interface.

Provides memory-mapped register access to the RX72N GPTW peripheral for 32-bit PWM generation in motor control applications.

Quick Start Example - Configure 20 kHz PWM:

```

// Get GPTW channel 0 for motor 0
volatile rx_gptw_channel_regs_t* gptw = gptw0();

// 1. Unlock write protection
gptw->gtwp = k_gptw_gtwp_unlock;

// 2. Stop counter during configuration
gptw->gter &= ~k_gptw_gter_cst;

// 3. Set mode: Sawtooth PWM, no prescaler (PCLKA/1 = 120 MHz)
gptw->gter = k_gptw_gter_md_saw_pwm | k_gptw_gter_tpcs_1;

// 4. Set period for 20 kHz: 120 MHz / 20 kHz - 1 = 5999
gptw->gtpr = 5999;

// 5. Set initial duty to 0%
gptw->gtccra = 0;

// 6. Configure GTIOCA output: initial low, high at end-of-cycle, low at compare match
gptw->gtior = k_gptw_gtior_oa_init_low | k_gptw_gtior_oae;

// 7. Clear counter
gptw->gtcnt = 0;

// 8. Start counting
gptw->gter |= k_gptw_gter_cst;

// 9. Lock write protection
gptw->gtwp = k_gptw_gtwp_lock;

// Update duty cycle to 50%
gptw->gtwp = k_gptw_gtwp_unlock;
gptw->gtccra = 3000; // 50% of 5999
gptw->gtwp = k_gptw_gtwp_lock;

```

### 5.3.2 Data Structure Documentation

#### 5.3.2.1 struct rx'gptw'channel'regs't

GPTW Channel Register Map for 32-bit PWM generation.

Memory-mapped register structure for a single GPTW channel. Each of the 4 channels (GPTW0↔GPTW3) has an identical register layout at different base addresses spaced 0x100 bytes apart.

Channel Base Addresses:

| Channel | Base Address | Motor | Output Pins      |
|---------|--------------|-------|------------------|
| GPTW0   | 0x000C2000   | M0    | PE5 (A), PE2 (B) |
| GPTW1   | 0x000C2100   | M1    | PE4 (A), PE1 (B) |
| GPTW2   | 0x000C2200   | M2    | PE3 (A), PE0 (B) |
| GPTW3   | 0x000C2300   | M3    | PE7 (A), PE6 (B) |

Key Registers for Motor PWM:

| Register | Offset | Description                           |
|----------|--------|---------------------------------------|
| GTWP     | 0x00   | Write protection (unlock: 0xA500)     |
| GTCR     | 0x2C   | Control (mode, prescaler, start/stop) |
| GTIOR    | 0x34   | I/O control (output polarity/enable)  |
| GTCNT    | 0x48   | 32-bit counter value                  |
| GTCCRA   | 0x4C   | Compare A (duty cycle for GTIOCA)     |
| GTCCRB   | 0x50   | Compare B (duty cycle for GTIOCB)     |
| GTPR     | 0x64   | Period (PWM frequency)                |
| GTDTCR   | 0x88   | Dead-time control                     |
| GTDVU    | 0x8C   | Dead-time value (rising edge)         |
| GTDVD    | 0x90   | Dead-time value (falling edge)        |

PWM Frequency Calculation:

$$f_{PWM} = \frac{f_{PCLKA}}{(GTPR+1) \times Prescaler}$$

Duty Cycle Calculation:

$$Duty\% = \frac{GTCCRA}{GTPR+1} \times 100\%$$

Usage Example - Dead-Time Configuration:

```
volatile rx_gptw_channel_regs_t* gptw = gptw0();

// Enable dead-time generation
gptw->gtdtcr = k_gptw_gtdtcr_tde;

// Set dead-time: 500 ns @ 120 MHz = 60 counts
gptw->gtdvu = 60; // Rising edge dead-time
gptw->gtdvd = 60; // Falling edge dead-time
```

Invariant

`sizeof(rx_gptw_channel_regs_t) == 0xD8` (216 bytes)

Channel spacing is exactly 0x100 bytes

### 5.3.2.2 struct rx\_gptw\_common\_regs\_t

GPTW Common Register Map.

Overlays GPTW0.GTSTR/GTSTP/GTCLR to provide a named handle for multi-channel atomic start/↵ stop/clear. Writing bits [3:0] in any of these registers affects channels 0-3 simultaneously (per RX72N HW manual section 26.2.2-26.2.4). Base address: [k\\_gptw\\_common\\_base\\_addr](#) (0x000C2004) == GPTW0.↵ GTSTR. The RX72N address map has no separate "common" GPTW block; the per-channel GTSTR/↵ GTSTP/GTCLR registers are cross-channel by design.

Definition at line 328 of file [rx72n\\_gptw\\_regs.h](#).

Collaboration diagram for [rx\\_gptw\\_common\\_regs\\_t](#):

```

### 5.3.3.12 gptw\_gtintad\_bits\_t

```
enum gptw_gtintad_bits_t : uint32_t
```

GTINTAD register bit definitions for POEG group linkage.

The GTINTAD register (offset 0x38) configures the link between a GPTW channel and a POEG group for emergency output stop. When a fault is detected (dead-time error, simultaneous high/low output), the GPTW signals the selected POEG group to disable PWM outputs.

STAR Project Usage:

| GPTW Channel | POEG Group | GRP[1:↔0] | Motor |
|--------------|------------|-----------|-------|
| GPTW0        | A          | 00        | 0     |
| GPTW1        | B          | 01        | 1     |
| GPTW2        | C          | 10        | 2     |
| GPTW3        | D          | 11        | 3     |

Warning

GRP[1:0] must be set while OAE and OBE in GTIOR are 0

## 5.4 RX72N ICU Register Definitions

Interrupt Controller Unit hardware register interface.

Data Structures

- struct [rx\\_dmrsr\\_entry\\_t](#)  
DMAC Module Start Register entry with 4-byte alignment.
- struct [rx\\_icu\\_regs\\_t](#)  
ICU Register Map for Interrupt Controller Unit.

## Enumerations

- enum `rx_icu_addresses_t` : `uintptr_t` { `k_icu_base_addr` = 0x00087000 , `k_icu_slibr_base_addr` = 0x00087700 , `k_icu_sliar_base_addr` = 0x00087900 }  
ICU peripheral base address.
- enum `icu_reserved_sizes_t` : `uint16_t` {  
`k_icu_reserved_after_ier_bytes` = 192 , `k_icu_reserved_after_swint2r_bytes` = 14 ,  
`k_icu_reserved_after_fir_bytes` = 14 , `k_icu_reserved_after_dmrsrc_bytes` = 224 ,  
`k_icu_reserved_after_irqcr_bytes` = 16 , `k_icu_reserved_after_irqfite_bytes` = 6 , `k_icu_reserved_after_irqfite`  
= 84 , `k_icu_reserved_after_exnmiclr_bytes` = 9 ,  
`k_icu_reserved_after_nmifite_bytes` = 3 , `k_icu_reserved_after_nmifite_bytes` = 491 ,  
`k_icu_reserved_after_slibr_bytes` = 512 , `k_icu_dmrsrc_entry_padding` = 3 }  
ICU register reserved field sizes for structure padding.
- enum `icu_array_sizes_t` : `uint16_t` {  
`k_icu_ir_count` = 256 , `k_icu_dtcer_count` = 256 , `k_icu_ier_count` = 32 , `k_icu_ier_bits_per_reg`  
= 8 ,  
`k_icu_ipr_count` = 256 , `k_icu_dmrsrc_count` = 8 , `k_icu_irqcr_count` = 16 , `k_icu_irqfite_count`  
= 2 ,  
`k_icu_irqfite_count` = 2 , `k_icu_slibxr_count` = 16 , `k_icu_slibr_count` = 64 , `k_icu_sliar_count`  
= 48 }  
ICU register array dimensions.
- enum `rx_cmt_interrupt_vector_t` : `uint8_t` { `k_vect_cmt0_cmi0` = 28 , `k_vect_cmt1_cmi1` = 29 }  
CMT (Compare Match Timer) interrupt vector numbers.
- enum `rx_sci_interrupt_vector_t` : `uint8_t` { `k_vect_sci9_rx9` = 102 }  
SCI (Serial Communications Interface) interrupt vector numbers.
- enum `rx_interrupt_priority_t` : `uint8_t` { `k_ipr_level_disable` = 0 , `k_ipr_level_min` = 1 ,  
`k_ipr_level_max` = 15 }  
Interrupt priority levels for IPR registers.

## Functions

- static volatile `rx_icu_regs_t` \* `icu` (void)  
Get pointer to ICU registers.
- static volatile `uint8_t` \* `icu_slibr` (`uint8_t` vec)  
Get pointer to ICU SLIBR source-select register for a SELECTB vector.

## 5.4.1 Detailed Description

Interrupt Controller Unit hardware register interface.

Provides memory-mapped register access to the RX72N ICU peripheral for interrupt configuration, enabling, and priority management.

Quick Start Example - Enable CMT0 Interrupt:

```
volatile rx_icu_regs_t* icu_regs = icu();

// 1. Clear any pending interrupt request
icu_regs->ir[k_vect_cmt0_cmi0] = 0x00;

// 2. Set priority (1=lowest, 15=highest, 0=disabled)
icu_regs->ipr[k_vect_cmt0_cmi0] = 10; // Priority 10

// 3. Enable interrupt in IER register
// IER[3] bit 4 = vector 28 (CMT0_CMI0)
// IER index = vector / 8, bit = vector % 8
uint8_t ier_index = k_vect_cmt0_cmi0 / 8; // = 3
uint8_t ier_bit = k_vect_cmt0_cmi0 % 8; // = 4
icu_regs->ier[ier_index] |= (1U << ier_bit);

// 4. Enable global interrupts (in PSW register, done separately)
```

## 5.4.2 Data Structure Documentation

### 5.4.2.1 struct rx\_dmr\_entry\_t

DMAC Module Start Register entry with 4-byte alignment.

The DMRSR registers are 8-bit registers but located at 4-byte aligned addresses (0x400, 0x404, 0x408, 0x40C, 0x410, 0x414, 0x418, 0x41C). This structure provides proper padding to match the hardware layout.

Manual Reference:

Ch15 Section 15.2.8 - DMRSR0-7 addresses:

- DMRSR0: 0x00087400
- DMRSR1: 0x00087404
- DMRSR2: 0x00087408
- DMRSR3: 0x0008740C
- DMRSR4: 0x00087410
- DMRSR5: 0x00087414
- DMRSR6: 0x00087418
- DMRSR7: 0x0008741C

Usage:

```
// Set DMAC channel 0 trigger to vector 28 (CMT0)
icu()->dmrsr[0].reg = 28;

// Set DMAC channel 3 trigger to USB vector
icu()->dmrsr[3].reg = 102;
```

Note

Each DMRSR register selects the interrupt vector number that triggers the corresponding DMAC channel transfer.

Warning

Do not set the same vector number for multiple DMRSR registers.  
Do not set the same interrupt as both DTC and DMAC trigger.

Definition at line 288 of file [rx72n\\_icu\\_regs.h](#).

Collaboration diagram for rx\_dmr\_entry\_t:

|                  |                                          |                              |
|------------------|------------------------------------------|------------------------------|
| volatile uint8_t | reg                                      | 8-bit vector number register |
| uint8_t          | reserved↵<br>[k_icu_dmrsr_entry_padding] | Padding to 4-byte boundary   |

## 5.4.2.2 struct rx\_icu\_regs\_t

ICU Register Map for Interrupt Controller Unit.

Memory-mapped register structure for the ICU peripheral. This structure provides direct hardware access to interrupt control registers including request flags, enable control, priorities, and external IRQ configuration.

Interrupt Handling Workflow:

1. Peripheral generates interrupt request -> IR[vector] = 1
2. ICU checks IER[vector/8] bit (vector%8) for enable
3. If enabled, ICU checks IPR[vector] for priority (1-15)
4. Higher priority interrupts preempt lower priority
5. CPU vectors to interrupt handler
6. Handler clears IR[vector] = 0 before returning

Usage Example - Configure Multiple Interrupts:

```
volatile rx_icu_regs_t* icu_regs = icu();

// Disable all interrupts during configuration
// (typically done with PSW.I bit, not shown here)

// Configure CMT0 (vector 28) - System tick at priority 10
icu_regs->ir[28] = 0; // Clear pending
icu_regs->ipr[28] = 10; // Priority 10
icu_regs->ier[3] |= 0x10; // Enable (IER3 bit 4)

// Configure CMT1 (vector 29) - Motor control at priority 12
icu_regs->ir[29] = 0; // Clear pending
icu_regs->ipr[29] = 12; // Priority 12 (higher than tick)
icu_regs->ier[3] |= 0x20; // Enable (IER3 bit 5)

// Configure USB (vector 102) - Communication at priority 8
icu_regs->ir[102] = 0; // Clear pending
icu_regs->ipr[102] = 8; // Priority 8
icu_regs->ier[12] |= 0x40; // Enable (IER12 bit 6)

// Re-enable global interrupts (PSW.I = 1)
```

Memory Layout (Total: ~2562 bytes):

| Offset | Size | Field         | Description             |
|--------|------|---------------|-------------------------|
| 0x000  | 256  | ir↵<br>[256]↵ | Interrupt Request flags |

| Offset | Size | Field           | Description                           |

| 0xA01  | 1    | selexdr         | Selectable ext int direction          |

#### Note

Register layout verified against RX72N Manual Ch15, Rev.1.20

#### Warning

All registers are memory-mapped and must be accessed as volatile.  
Some IR/IPR indices (0-15) are reserved and must not be accessed.

## Invariant

IR flags are read-write: write 0 to clear, read to check status

IPR values must be 0-15 (0 disables, 1-15 sets priority)

IER bits: 1=enabled, 0=disabled

### 5.4.3 Enumeration Type Documentation

#### 5.4.3.1 icu\_array\_sizes\_t

```
enum icu_array_sizes_t : uint16_t
```

ICU register array dimensions.

Defines the sizes of register arrays in the ICU. These values are used to dimension arrays in the `rx_icu_regs_t` structure.

Register Array Purpose:

- IR[256]: One flag per interrupt vector (vectors 0-255)
- DTCER[256]: One enable bit per DTC-capable vector
- IER[32]: 8 bits per register, covering 256 vectors (32 x 8 = 256)
- IPR[256]: One priority level per interrupt vector
- DMRSR[8]: DMAC channel 0-7 start source selection (4-byte aligned)
- IRQCR[16]: External IRQ0-15 edge/level configuration

Enumerator

|                        |                                                |
|------------------------|------------------------------------------------|
| k_icu_ir_count         | 256 interrupt request flags (one per vector)   |
| k_icu_dtcer_count      | 256 DTC enable flags                           |
| k_icu_ier_count        | 32 enable registers x 8 bits = 256 vectors     |
| k_icu_ier_bits_per_reg | Each IER controls 8 interrupt enables          |
| k_icu_ipr_count        | 256 priority registers (0-15 each)             |
| k_icu_dmrsr_count      | 8 DMAC channels                                |
| k_icu_irqcr_count      | 16 external IRQ pins (IRQ0-15)                 |
| k_icu_irqfte_count     | 2 filter enable registers (16 bits total)      |
| k_icu_irqftc_count     | 2 filter clock registers                       |
| k_icu_slibxr_count     | SLIBXRn entries: vectors 128-143 (INTB128-143) |
| k_icu_slibr_count      | SLIBRn entries: vectors 144-207 (INTB144-207)  |
| k_icu_sliar_count      | SLIARn entries: vectors 208-255 (INTA208-255)  |

```

#### 5.4.3.2 icu\_reserved\_sizes\_t

```
enum icu_reserved_sizes_t : uint16_t
```

ICU register reserved field sizes for structure padding.

Defines byte sizes for reserved regions in the ICU register map. These ensure proper alignment and offset matching between the C structure and actual hardware register locations.

## Warning

Do not modify these values - they are derived from the RX72N hardware register layout specification (Ch15).

## 5.4.3.3 rx\_cmt\_interrupt\_vector\_t

```
enum rx_cmt_interrupt_vector_t : uint8_t
```

CMT (Compare Match Timer) interrupt vector numbers.

Vector numbers for CMT peripheral interrupts. These are used to index into IR[], IER[], and IPR[] arrays.

IER/Bit Calculation:

- IER index = vector / 8
- IER bit = vector % 8

Example: CMT0 (vector 28)

- IER[3] (28/8=3), bit 4 (28%8=4)
- IPR[28] for priority

See also

RX72N Manual Ch15 Table 15.4 for complete vector list

00193 } rx_icu_addresses_t;

```

## 5.4.3.5 rx\_interrupt\_priority\_t

```
enum rx_interrupt_priority_t : uint8_t
```

Interrupt priority levels for IPR registers.

Priority values for the IPR[n] registers. Higher values mean higher priority. A running interrupt can only be preempted by an interrupt with strictly higher priority.

Priority Guidelines for STAR Project:

| Priority | Usage                   | Example           |
|----------|-------------------------|-------------------|
| 15       | Reserved for NMI/faults | Hardware fault    |
| 12-14    | Time-critical motor     | Motor PWM sync    |
| 9-11     | Real-time control       | CMT tick, encoder |
| 6-8      | Communication           | USB, UART RX      |
| 3-5      | Background processing   | UART TX, DMA      |
| 1-2      | Low priority            | Diagnostics       |
| 0        | Disabled                | Unused interrupts |

## Warning

Setting two interrupts to the same priority is allowed but undefined which will be serviced first if both are pending

## Enumerator

|                     |                                          |
|---------------------|------------------------------------------|
| k_ipr_level_disable | Interrupt disabled (will not trigger)    |
| k_ipr_level_min     | Minimum enabled priority (lowest)        |
| k_ipr_level_max     | Maximum priority (highest, preempts all) |

Definition at line 582 of file [rx72n\\_icu\\_regs.h](#).

```
00582 : uint8_t {
00583 k_ipr_level_disable = 0, /**< Interrupt disabled (will not trigger) */
00584 k_ipr_level_min = 1, /**< Minimum enabled priority (lowest) */
00585 k_ipr_level_max = 15, /**< Maximum priority (highest, preempts all) */
00586 } rx_interrupt_priority_t;
```

## 5.4.3.6 rx\_sci\_interrupt\_vector\_t

```
enum rx_sci_interrupt_vector_t : uint8_t
```

SCI (Serial Communications Interface) interrupt vector numbers.

Vector numbers for SCI peripheral receive/transmit interrupts. Used to index into IR[], IER[], and IPR[] arrays per RX72N HUM Table 14.3.

IER/Bit Calculation:

- IER index = vector / 8
- IER bit = vector % 8

Example: SCI9 RXI9 (vector 102)

- IER[12] (102/8=12), bit 6 (102%8=6)
- IPR[102] for priority

|                  |                                                           |
|------------------|-----------------------------------------------------------|
| k_vect_sci9_rxi9 | SCI9 receive data full: IER[12] bit 6, STAR debug UART RX |
|------------------|-----------------------------------------------------------|

Definition at line 554 of file [rx72n\\_icu\\_regs.h](#).

```
00554 : uint8_t {
00555 k_vect_sci9_rxi9 = 102, /**< SCI9 receive data full: IER[12] bit 6, STAR debug UART RX */
00556 } rx_sci_interrupt_vector_t;
```

## 5.4.4 Function Documentation

### 5.4.4.1 icu()

```
volatile rx_icu_regs_t * icu (
 void) [inline], [static]
```

Get pointer to ICU registers.

Returns a volatile pointer to the ICU register structure, enabling direct hardware register access for interrupt configuration.

Returns

Volatile pointer to ICU register structure at 0x00087000

Precondition

No prerequisites - ICU is always accessible

Postcondition

Pointer is immediately usable for register access

No hardware state is modified by this function

Note

Thread Safety: Function is reentrant (returns constant address)

Performance: Zero overhead - compiles to single load instruction

Warning

Interrupt configuration should be done with global interrupts disabled to prevent race conditions

Example - Enable/Disable Specific Interrupt:

```
volatile rx_icu_regs_t* icu_regs = icu();

// Calculate IER index and bit for vector 28
uint8_t vector = 28;
uint8_t ier_idx = vector / 8; // = 3
uint8_t ier_bit = vector % 8; // = 4

// Enable interrupt
icu_regs->ier[ier_idx] |= (1U « ier_bit);

// Disable interrupt
icu_regs->ier[ier_idx] &= ~(1U « ier_bit);

// Check if interrupt is pending
if (icu_regs->ir[vector]) {
 // Interrupt is pending
 icu_regs->ir[vector] = 0; // Clear it
}
```

Here is the caller graph for this function:

#### 5.4.4.2 icu\_slibr()

```
volatile uint8_t * icu_slibr (
 uint8_t vec) [inline], [static]
```

Get pointer to ICU SLIBR source-select register for a SELECTB vector.

SLIBR is a byte-wide table at 0x00087700 indexed by absolute vector number, covering SELECTB slots 144..207 (RX72N HW manual Ch15 Section 15.2 and hirakuni45/RX RX72N/icu.hpp line 824). Writing a SELECTB source code (e.g. `k_usb0_usbi_sli_src = 62`) into `SLIBR[vec]` routes that peripheral interrupt onto vec. Vectors outside 144..207 have no backing register – writes are ignored and reads return 0.

Parameters

|    |     |                                                        |
|----|-----|--------------------------------------------------------|
| in | vec | Absolute vector number in the SELECTB range (144..207) |
|----|-----|--------------------------------------------------------|

Returns

`volatile uint8_t*` Pointer to `SLIBR[vec]`

Definition at line 508 of file [rx72n\\_icu\\_regs.h](#).

```
00509 {
00510 return (volatile uint8_t*)(k_icu_slibr_base_addr + (uintptr_t)vec);
00511 }
```

## 5.5 MPC Register Definitions

Multi-Function Pin Controller (MPC) hardware register interface.

Collaboration diagram for MPC Register Definitions:

Topics

- [MPC Static Assertions](#)  
Compile-time verification of MPC register layout.

Data Structures

- struct [rx\\_pfs\\_regs\\_t](#)  
Pin Function Select Register (C bitfield).
- struct [rx\\_mpc\\_regs\\_t](#)  
MPC Register Map.

## Enumerations

- enum `rx_mpc_addresses_t` : `uintptr_t` { `k_mpc_base_addr` = 0x0008C100 }  
MPC base address (verified against RX72N Hardware Manual Ch23).
- enum `mpc_register_offsets_t` : `uint8_t` {  
`k_mpc_offset_pwpr` = 0x1F , `k_mpc_offset_pfs` = 0x40 , `k_mpc_offset_port5_pfs` = 0x28 ,  
`k_mpc_offset_porta_pfs` = 0x50 ,  
`k_mpc_offset_porte_pfs` = 0x70 , `k_mpc_offset_portj_pfs` = 0x90 , `k_mpc_pfs_total_bytes` }  
Byte offsets of key MPC registers from the MPC base address (0x0008C100).
- enum `mpc_reserved_sizes_t` : `uint8_t` {  
`k_mpc_reserved1_bytes` = 1 , `k_mpc_reserved2_bytes` = 4 , `k_mpc_reserved3_bytes` = 16 ,  
`k_mpc_reserved4_bytes` = 8 ,  
`k_mpc_dscr2_count` = 24 , `k_port3_reserved_bytes` = 3 , `k_port5_reserved_bytes` = 1 ,  
`k_port6_reserved_bytes` = 1 ,  
`k_port7_reserved_bytes` = 1 , `k_portf_reserved1_bytes` = 2 , `k_portf_reserved2_bytes` = 2 ,  
`k_portj_reserved1_bytes` = 1 ,  
`k_portj_reserved2_bytes` = 2 }  
MPC register reserved field sizes.
- enum `mpc_pwpr_bits_t` : `uint8_t` { `k_mpc_pwpr_pfswe` = (1 << 6) , `k_mpc_pwpr_b0wi` = (1 << 7) }  
MPC Write Protect Register (PWPR) bit definitions.
- enum `pfs_bits_t` : `uint8_t` { `k_pfs_psel_mask` = 0x1F , `k_pfs_isel` = (1 << 6) , `k_pfs_asel` = (1 << 7) }  
Pin Function Select (PFS) register bit definitions.

## Functions

- static volatile `rx_mpc_regs_t` \* `mpc` (void)  
Get pointer to MPC registers.

### 5.5.1 Detailed Description

Multi-Function Pin Controller (MPC) hardware register interface.

### 5.5.2 Data Structure Documentation

#### 5.5.2.1 struct rx`pfs`regs`t

Pin Function Select Register (C bitfield).

Each pin has a PFS register controlling peripheral function selection.

This struct uses C bitfields (the : N syntax) to pack multiple fields into a single byte, matching the hardware register layout exactly:

Bit layout in hardware register (1 byte):

```

7 6 5 4 3 2 1 0
+-----+
| ASEL | ISEL | Reserved | PSEL[4:0] |
+-----+
```

The syntax `volatile uint8_t` name : bits defines a bitfield where:

- name is the field name (or omitted for padding/reserved bits)
- bits is the number of bits the field occupies

Example: `psel : 5` means `psel` occupies 5 bits (bits 0-4)

This is standard C (not C++) and commonly used in embedded systems for hardware register definitions where bits are packed together.

Definition at line 234 of file `rx72n_mpc_regs.h`.

Collaboration diagram for `rx_pfs_regs_t`:

#### Data Fields

|                               |                            |                                                     |
|-------------------------------|----------------------------|-----------------------------------------------------|
| <code>uint8_t</code>          | <code>___pad0___: 1</code> | Reserved bit (bit 5) - unnamed bitfield for padding |
| <code>volatile uint8_t</code> | <code>asel: 1</code>       | Analog Input Select (bit 7)                         |
| <code>volatile uint8_t</code> | <code>isel: 1</code>       | Interrupt Input Select (bit 6)                      |
| <code>volatile uint8_t</code> | <code>psel: 5</code>       | Peripheral Select (bits 0-4)                        |

#### 5.5.2.2 struct `rx_mpc_regs_t`

MPC Register Map.

Multi-Function Pin Controller (MPC) registers for pin function selection. Controls which peripheral function each GPIO pin is assigned to. Base address: 0x0008C100

CRITICAL: This struct matches the exact hardware memory layout!

- 0x0008C100: Bus control registers (PFCSE, PFCSS, PFAOE, PFBCR, PFENET)
- 0x0008C11F: PWPR (Write Protect Register)
- 0x0008C140: PFS registers start (P00PFS)

Package Support (144-pin LFQFP R5F572NNHxFB):

- Available ports: 0-9 (partial), A-E (full), F (partial), J (partial: PJ3, PJ5)
- Not available on 144-pin: G, H
- Note: All ports are defined for compatibility with larger packages

Complete Memory Layout:

- 0x0008C100: PFCSE (CS Output Enable Register)
- 0x0008C101: Reserved (1 byte)
- 0x0008C102-0x0008C103: PFCSS0, PFCSS1 (CS Output Pin Select)
- 0x0008C104-0x0008C105: PFAOE0, PFAOE1 (Address Output Enable)
- 0x0008C106-0x0008C109: PFBCR0-3 (External Bus Control)
- 0x0008C10A-0x0008C10D: Reserved (4 bytes)
- 0x0008C10E: PFENET (Ethernet Control)
- 0x0008C10F-0x0008C11E: Reserved (16 bytes)
- 0x0008C11F: PWPR (Write Protect Register)
- 0x0008C120-0x0008C127: Reserved (8 bytes)
- 0x0008C128-0x0008C13F: DSCR2 (Drive Capacity Control, 24 bytes)
- 0x0008C140+: PFS registers (P00PFS through PJPFS, 152 bytes)

### 5.5.3 Enumeration Type Documentation

#### 5.5.3.1 mpc\_pwpr\_bits\_t

```
enum mpc_pwpr_bits_t : uint8_t
```

MPC Write Protect Register (PWPR) bit definitions.

The PWPR register protects PFS registers from accidental writes. A specific unlock sequence is required to modify any PFS register.

## PWPR Register Layout

| * Bit | Name  | Description                                 |
|-------|-------|---------------------------------------------|
| * 7   | B0WI  | PFSWE Bit Write Disable (1=PFSWE protected) |
| * 6   | PFSWE | PFS Write Enable (1=PFS writes allowed)     |
| * 5-0 | -     | Reserved                                    |
| *     |       |                                             |

## Unlock Sequence

1. Write 0x00 to PWPR (clear B0WI)
2. Write 0x40 to PWPR (set PFSWE)
3. Write to desired PFS register(s)
4. Write 0x00 to PWPR (clear PFSWE)
5. Write 0x80 to PWPR (set B0WI)

## Warning

Failing to re-lock after configuration leaves PFS vulnerable!

## Enumerator

|                  |                                              |
|------------------|----------------------------------------------|
| k_mpc_pwpr_pfswe | Bit 6: PFS Write Enable (1=allow writes)     |
| k_mpc_pwpr_b0wi  | Bit 7: PFSWE Write Disable (1=protect PFSWE) |

Definition at line 495 of file [rx72n\\_mpc\\_regs.h](#).

```

00495 : uint8_t {
00496 k_mpc_pwpr_pfswe = (1 « 6), /**< Bit 6: PFS Write Enable (1=allow writes) */
00497 k_mpc_pwpr_b0wi = (1 « 7), /**< Bit 7: PFSWE Write Disable (1=protect PFSWE) */
00498 } mpc_pwpr_bits_t;

```

## 5.5.3.2 mpc`register`offsets`t

```
enum mpc_register_offsets_t : uint8_t
```

Byte offsets of key MPC registers from the MPC base address (0x0008C100).

These constants are used in `static_assert` calls to verify the struct layout matches the hardware register map. Each constant encodes the exact byte offset from either the MPC base or the PFS block base (P00PFS), as noted.

## Note

All values verified against RX72N Manual Chapter 23, Section 23.2

Since

Version 1.0.0

Enumerator

00207 } mpc_reserved_sizes_t;

```

#### 5.5.3.4 pfs\_bits\_t

```
enum pfs_bits_t : uint8_t
```

Pin Function Select (PFS) register bit definitions.

Each GPIO pin has a PFS register controlling its function assignment. The PSEL field selects which peripheral function the pin is connected to.

#### PFS Register Layout

```

* Bit | Name | Description
* ----+-----+-----
* 7 | ASEL | Analog Input Select (1=analog function)
* 6 | ISEL | IRQ Input Select (1=IRQ input enabled)
* 5 | Reserved | Always write 0
* 4-0 | PSEL[4:0] | Peripheral function select (0x00-0x1F)
*

```

#### Note

PSEL values are pin-specific. Check RX72N Manual Appendix for the function assignment table for each pin.

#### Enumerator

|                 |                                  |

00525 } pfs_bits_t;

```

## 5.5.3.5 rx\_mpc\_addresses\_t

enum `rx_mpc_addresses_t` : `uintptr_t`

MPC base address (verified against RX72N Hardware Manual Ch23).

The MPC module is located at a single base address. All registers are accessed relative to this base.

Enumerator

|                              |                           |
|------------------------------|---------------------------|
| <code>k_mpc_base_addr</code> | MPC register base address |
|------------------------------|---------------------------|

Definition at line 163 of file `rx72n_mpc_regs.h`.

```
00163 : uintptr_t {
00164 k_mpc_base_addr = 0x0008C100, /**< MPC register base address */
00165 } rx_mpc_addresses_t;
```

## 5.5.4 Function Documentation

## 5.5.4.1 mpc()

volatile `rx_mpc_regs_t` \* `mpc` (  
void ) [inline], [static]

Get pointer to MPC registers.

Returns a volatile pointer to the MPC register structure at address 0x0008C100. Provides access to all MPC registers including PWPR and PFS registers.

Returns

Volatile pointer to MPC register structure

Example

```
// Unlock, configure pin, re-lock
mpc()->pwpr = 0x00; // Clear B0WI
mpc()->pwpr = k_mpc_pwpr_pfswe; // Enable PFS write
mpc()->pb7pfs = 0x0A; // SC19 TXD
mpc()->pwpr = 0x00; // Clear PFSWE
mpc()->pwpr = k_mpc_pwpr_b0wi; // Protect PFSWE
```

Definition at line 464 of file `rx72n_mpc_regs.h`.

```
00465 {
00466 return (volatile rx_mpc_regs_t*)k_mpc_base_addr;
00467 }
```

References `k_mpc_base_addr`.

Referenced by `internal_configure_mpc()`, `internal_get_pfs_register()`, `internal_mpc_lock()`, and `internal_mpc_unlock()`.

Here is the caller graph for this function:

### 5.5.5 MPC Static Assertions

Compile-time verification of MPC register layout.

Collaboration diagram for MPC Static Assertions:

Compile-time verification of MPC register layout.

These static assertions are verified at compile time to ensure the C structure definitions match the actual hardware register layout. A failed assertion indicates a bug in the register definitions that must be fixed before the code can compile.

## 5.6 MTU Register Definitions

### Data Structures

- struct [rx\\_mtu\\_channel\\_regs\\_t](#)  
Standard MTU channel register map (MTU0-MTU2).
- struct [rx\\_mtu3\\_channel\\_regs\\_t](#)  
MTU3 register map accessed via base address 0x000C1200.
- struct [rx\\_mtu12\\_phase\\_regs\\_t](#)  
MTU1/MTU2 extended register map for 32-bit phase counting mode.
- struct [rx\\_mtu\\_tstr\\_regs\\_t](#)  
MTU Start Register Map.

### Enumerations

- enum [rx\\_mtu\\_addresses\\_t](#) : [uintptr\\_t](#) {  
[k\\_mtu0\\_base\\_addr](#) = 0x000C1300 , [k\\_mtu1\\_base\\_addr](#) = 0x000C1380 , [k\\_mtu2\\_base\\_addr](#) = 0x000C1400 , [k\\_mtu3\\_base\\_addr](#) = 0x000C1200 ,  
[k\\_mtu4\\_base\\_addr](#) = ([k\\_mtu3\\_base\\_addr](#) + 1U) , [k\\_mtu5u\\_base\\_addr](#) = 0x000C1C80 ,

`k_mtu12p_off_tgrblw` = 0x28U , `k_mtu12p_struct_size` = 0x2CU }

Byte offsets of registers within `rx_mtu12_phase_regs_t`.

- enum `mtu_periph_space_t` : `uintptr_t` { `k_mtu_periph_space_mask` = `0xFFFF0000U` , `k_mtu_periph_space_base` = `0x000C0000U` }

Address space mask and expected base for MTU peripheral verification.

## Functions

- static volatile `rx_mtu_channel_regs_t` \* `mtu0` (void)  
Get pointer to MTU0 registers.
- static volatile `rx_mtu_channel_regs_t` \* `mtu1` (void)  
Get pointer to MTU1 registers (16-bit mode).
- static volatile `rx_mtu_channel_regs_t` \* `mtu2` (void)  
Get pointer to MTU2 registers (16-bit mode).
- static volatile `rx_mtu12_phase_regs_t` \* `mtu1_phase` (void)  
Get pointer to MTU1 extended registers for 32-bit phase counting mode.
- static volatile `rx_mtu12_phase_regs_t` \* `mtu2_phase` (void)  
Get pointer to MTU2 extended registers for 32-bit phase counting mode.
- static volatile `rx_mtu3_channel_regs_t` \* `mtu3` (void)  
Get pointer to MTU3 registers via `rx_mtu3_channel_regs_t` struct.
- static volatile void \* `mtu4` (void)  
Get raw base address pointer for MTU4 register access.
- static volatile `rx_mtu3_channel_regs_t` \* `mtu6` (void)  
Get pointer to MTU6 registers (interleaved layout, identical to MTU3).
- static volatile void \* `mtu7` (void)  
Get raw base address pointer for MTU7 register access.
- static volatile `rx_mtu_tstr_regs_t` \* `mtu_tstra` (void)  
Get pointer to MTU TSTRA registers (MTU0-4, MTU8).
- static volatile `rx_mtu_tstr_regs_t` \* `mtu_tstrb` (void)  
Get pointer to MTU TSTRB registers (MTU6-7).

### 5.6.1 Detailed Description

### 5.6.2 Data Structure Documentation

#### 5.6.2.1 struct rx\_mtu\_channel\_regs\_t

Standard MTU channel register map (MTU0-MTU2).

Memory-mapped register structure for consecutive-layout 16-bit MTU channels. This structure applies to MTU0, MTU1, and MTU2 only. MTU6 and MTU7 have an interleaved register layout identical to MTU3/MTU4 and must be accessed via `mtu6()` which returns `rx_mtu3_channel_regs_t*`.

Register Memory Layout (18 bytes total)

| * Offset | Size | Register | Description                                   |
|----------|------|----------|-----------------------------------------------|
| * 0x00   | 1    | TCR      | Timer Control (prescaler, edge, clear source) |
| * 0x01   | 1    | TMDR     | Timer Mode (normal, PWM1, PWM2, phase count)  |
| * 0x02   | 1    | TIORH    | Timer I/O Control H (TIOCA/TIOCB output mode) |
| * 0x03   | 1    | TIORL    | Timer I/O Control L (TIOCC/TIOCD output mode) |
| * 0x04   | 1    | TIER     | Timer Interrupt Enable (TGIA-D, overflow)     |
| * 0x05   | 1    | TSR      | Timer Status (interrupt flags, read to clear) |
| * 0x06   | 2    | TCNT     | Timer Counter (16-bit, counts up/down)        |
| * 0x08   | 2    | TGRA     | Timer General Register A (compare/capture)    |
| * 0x0A   | 2    | TGRB     | Timer General Register B (compare/capture)    |
| * 0x0C   | 2    | TGRC     | Timer General Register C (compare/capture)    |
| * 0x0E   | 2    | TGRD     | Timer General Register D (compare/capture)    |
| *        |      |          |                                               |

### Timer Operating Modes

The TMDR register MD bits select the operating mode:

- Normal (0x00): Free-running counter with compare match
- PWM Mode 1 (0x02): TGRA=period, TGRB=duty cycle
- PWM Mode 2 (0x03): TGRC/TGRD as buffer registers
- Phase Counting (0x04-0x07): Quadrature encoder input

### PWM Generation Example

```
// Configure MTU0 for 20 kHz PWM, 50% duty cycle
volatile rx_mtu_channel_regs_t* mtu = mtu0();

// Stop timer during configuration
mtu->tstra()->tstr &= ~k_mtu_tstr_cst0;

// Configure prescaler and clear source
mtu->tcr = k_mtu_tcr_tpsc_1 | k_mtu_tcr_cclr_tgra;

// Set PWM mode 1
mtu->tmdr = k_mtu_tmdr_md_pwm1;

// Configure output: low initially, high on compare match
mtu->tiorh = k_mtu_tior_init_low;

// Set period and duty cycle (120 MHz / 6000 = 20 kHz)
mtu->tgra = 5999; // Period
mtu->tgrb = 3000; // 50% duty (high for 3000 counts)

// Clear counter and start timer
mtu->tcnt = 0;
mtu_tstra()->tstr |= k_mtu_tstr_cst0;
```

### Invariant

Structure size must be exactly 18 bytes (0x10 offset)

All registers are volatile for hardware access

| volatile uint8_t | tsr  | <p>Timer Status Register (TSR) - interrupt flags. Contains interrupt flags; read to check, write 0 to clear.</p> <p>Warning</p> <p>Per RX72N HW manual R01UH0824EJ0111 Section 21.2 (MTU register tables), MTU0 has NO TSR at this offset – accessing this field via the MTU0 base (0x000C1300) targets a reserved byte and the result is undefined. This field is only valid on MTU channels that define a TSR (e.g., MTU1, MTU2, MTU3/4 TSR copies); callers must gate access by channel before reading/writing tsr.</p> |

### 5.6.2.2 struct rx\_mtu3\_channel\_regs\_t

MTU3 register map accessed via base address 0x000C1200.

Memory-mapped register structure for MTU3 channel, which supports complementary PWM generation for H-bridge motor driver control along with standard timer/counter and phase-counting encoder modes.

The MTU3/MTU4 peripheral block places MTU3 and MTU4 registers at INTERLEAVED addresses starting at 0x000C1200. MTU3 registers are NOT at consecutive byte offsets – there are large gaps between them where MTU4-specific registers and shared MTU3/4 control registers reside.

#### Warning

This struct is ONLY valid for MTU3 ([mtu3\(\)](#) base 0x000C1200). MTU4 registers have DIFFERENT offsets relative to the MTU4 base address (0x000C1201) and CANNOT use this struct. For MTU4, compute each register address individually using the Ch 5 I/O address table (e.g. MTU4.TIORH = 0x000C1206, not base+0x04). See RX72N Hardware Manual Ch 5 I/O Register Address Table.

```

#### Note

MTU3 has NO TGRF register. Only MTU4 has TGRF (at 0x000C1276).

#### Dead-Time Insertion via TGRE

TGRE provides dead-time values to prevent H-bridge shoot-through. MTU4.TGRE and MTU4.TGRF must be set separately using direct address access.

$$t_{dead} = \frac{TGRE}{f_{PCLKA}} = \frac{TGRE}{120 \text{ MHz}}$$

Example: 500ns dead-time requires TGRE = 60 (at 120 MHz PCLKA)

#### Complementary PWM Example

```

// Configure MTU3/4 for complementary PWM with 500ns dead-time
volatile rx_mtu3_channel_regs_t* mtu = mtu3();

// Stop both timers
mtu->tstra()->tstr &= ~(k_mtu_tstr_cst3 | k_mtu_tstr_cst4);

// Configure for complementary PWM mode (via TMDR1)
mtu->tmdr1 = 0x0D; // Complementary PWM mode

// Set period (TGRA) and duty cycle (TGRB)
mtu->tgra = 5999; // 20 kHz period at 120 MHz PCLKA
mtu->tgrb = 3000; // 50% duty cycle

// Set dead-time for MTU3 (TGRE at 0x000C1272)
mtu->tgre = 60; // 500ns at 120 MHz
// MTU4.TGRF must be set via direct address (MTU4 uses different struct offsets):
(volatile uint16_t)0x000C1276U = 60; // MTU4.TGRF = 500ns dead-time

// Enable buffer transfer on counter clear
mtu->tbtm = 0x03;

// Start both timers synchronously
mtu_tstra()->tstr |= (k_mtu_tstr_cst3 | k_mtu_tstr_cst4);

```

#### Invariant

Struct size is 0x74 bytes (116) covering MTU3 registers up to TGRE

Only valid when cast from `mtu3()` base address (0x000C1200)

MTU4 registers CANNOT use this struct (different relative offsets)

### 5.6.2.3 struct rx'mtu12'phase'regs't

MTU1/MTU2 extended register map for 32-bit phase counting mode.

Extended register structure for MTU1 and MTU2 when operating in 32-bit cascaded phase counting mode. This mode is ideal for quadrature encoder applications requiring high-resolution position tracking over extended ranges without software overflow handling.

### STAR Robot Encoder Configuration

The STAR robot uses 4x brushed DC gearmotors with Hall effect quadrature encoders. MTU1 and MTU2 are cascaded to provide 32-bit position tracking:

```

* Encoder Signals MTU1/MTU2 32-bit Cascaded Mode
* -----
*
* Motor 1 (FL) +-----+
* +-----+ | 32-bit TCNTLW |
* | Hall A --->+> MTCLKA --->| [MTU2.TCNT | MTU1.TCNT] |
* | Hall B --->+> MTCLKB --->| Upper 16 Lower 16 |
* +-----+ |
* 341 PPR x 4 edges | Position = TCNTLW / 1364 |
* = 1364 counts/rev | Range: +/-3.1M revolutions |
* +-----+
*

```

### 32-bit Cascaded Mode Benefits

- Extended Range:  $2^{32}$  counts vs  $2^{16}$  counts (65536x more range)
- Atomic Access: TCNTLW, TGRALW, TGRBLW are 32-bit atomic operations
- No Race Conditions: No need to disable interrupts during read
- Hardware Implementation: Zero software overhead for overflow tracking

## Position Calculation

For STAR robot Hall encoders (341 PPR, 4x quadrature = 1364 counts/rev):

$$\text{Position (revolutions)} = \frac{\text{TCNTLW}}{1364}$$

$$\text{Position (degrees)} = \frac{\text{TCNTLW} \times 360deg}{1364}$$

## Overflow Analysis

At maximum motor speed (210 RPM = 3.5 rev/sec):

$$t_{\text{overflow}} = \frac{2^{31}}{1364 \times 3.5} = 449,686 \text{ seconds} = 10.4 \text{ days}$$

## Register Memory Layout (44 bytes total)

| * Offset | Size | Register | Description                        |

| * 0x11   | 1    | TMDR3    | 32-bit mode control (LWA, PHCKSEL) |
| * 0x12   | 14   | Reserved | -                                  |
| * 0x20   | 4    | TCNTLW   | 32-bit cascaded counter (atomic)   |
| * 0x24   | 4    | TGRALW   | 32-bit general register A (atomic) |
| * 0x28   | 4    | TGRBLW   | 32-bit general register B (atomic) |
| *        |      |          |                                    |

## 32-bit Mode Configuration Example

```
// Configure MTU1+MTU2 for 32-bit quadrature encoder (Hall sensors)
volatile rx_mtu12_phase_regs_t* mtu = mtu1_phase();

// Stop timers during configuration
mtu->tstra()->tstr &= ~(k_mtu_tstr_cst1 | k_mtu_tstr_cst2);

// Configure for phase counting mode 4 (count on both edges)
mtu->tmdr = 0x04; // Phase counting mode 4

// Enable 32-bit cascaded mode (LWA bit) with both-edge counting
mtu->tmdr3 = k_mtu_tmdr3_lwa | k_mtu_tmdr3_phcksel;

// Clear 32-bit counter
mtu->tcntlw = 0;

// Start both timers
mtu->tstra()->tstr |= (k_mtu_tstr_cst1 | k_mtu_tstr_cst2);

// Read 32-bit position (atomic, no race condition)
int32_t position = (int32_t)mtu->tcntlw;
```

## Invariant

Structure size must be exactly 44 bytes (0x2C)

TMDR3 at offset 0x11 controls 32-bit cascaded mode

TCNTLW/TGRALW/TGRBLW are 32-bit aligned for atomic access

#### 5.6.2.4 struct rx\_mtu\_tstr\_regs\_t

MTU Start Register Map.

Timer start/stop control registers. Base addresses:

- TSTRA: 0x000C1280 (MTU0-4, MTU8)
- TSTRB: 0x000C1A80 (MTU6-7)

Definition at line 876 of file [rx72n\\_mtu\\_regs.h](#).

Collaboration diagram for rx\_mtu\_tstr\_regs\_t:

## Data Fields

|                  |      |                                            |
|------------------|------|--------------------------------------------|
| volatile uint8_t | tstr | Timer Start Register (channel enable bits) |
|------------------|------|--------------------------------------------|

## 5.6.3 Enumeration Type Documentation

## 5.6.3.1 mtu12`phase`padding`sizes` t

```
enum mtu12_phase_padding_sizes_t : uint8_t
```

Named padding array sizes for [rx\\_mtu12\\_phase\\_regs\\_t](#) reserved fields.

Each constant names the number of reserved bytes between two adjacent registers in the 32-bit phase counting register layout. Verified against RX72N Hardware Manual Ch 5 I/O Register Address Table.

Since

Version 1.0.0

## Enumerator

|                            |                                                                          |
|----------------------------|--------------------------------------------------------------------------|
| k_mtu12p_pad_before_tcntlw | 14 reserved bytes at offset 0x12-0x1F (gap before 32-bit long-word regs) |
|----------------------------|--------------------------------------------------------------------------|

Definition at line 662 of file [rx72n\\_mtu\\_regs.h](#).

```
00662 : uint8_t {
00663 /** @brief 14 reserved bytes at offset 0x12-0x1F (gap before 32-bit long-word regs) */
00664 k_mtu12p_pad_before_tcntlw = 14U,
00665 } mtu12_phase_padding_sizes_t;
```

## 5.6.3.2 mtu12`phase`reg`offsets` t

```
enum mtu12_phase_reg_offsets_t : uint8_t
```

Byte offsets of registers within [rx\\_mtu12\\_phase\\_regs\\_t](#).

Named constants for compile-time layout verification of the 32-bit phase counting register struct. Verified against RX72N Hardware Manual Ch 5 I/O Register Address Table and Ch 24 Table 24.11.

Since

Version 1.0.0

```

### 5.6.3.3 mtu3'padding'sizes't

```
enum mtu3_padding_sizes_t : uint8_t
```

Named padding array sizes for `rx_mtu3_channel_regs_t` reserved fields.

Each constant names the number of reserved bytes between two adjacent MTU3 registers in the hardware layout. The comments show which hardware registers occupy those byte ranges (verified against RX72N Ch 5 I/O Register Address Table).

```

#### 5.6.3.4 mtu3`reg`offsets`t

```
enum mtu3_reg_offsets_t : uint8_t
```

Byte offsets of MTU3 registers from base 0x000C1200.

Named constants for compile-time layout verification of [rx\\_mtu3\\_channel\\_regs\\_t](#). The MTU3/MTU4 interleaved layout means offsets are sparse – see the struct definition for the full picture of which bytes belong to MTU4 vs. shared regs. All values verified against RX72N Hardware Manual Ch 5 I/O Register Address Table.

Since

Version 1.0.0

01449 } mtu_channel_reg_offsets_t;
```

### 5.6.3.7 mtu\_periph\_space\_t

```
enum mtu_periph_space_t : uintptr_t
```

Address space mask and expected base for MTU peripheral verification.

Used in `static_assert` to verify MTU base addresses fall in the correct peripheral address space (0x000↔Cxxxx), as required by the RX72N memory map.

Since

Version 1.0.0

Enumerator

|                         |                                                       |

01544 k_mtu_periph_space_base = 0x000C0000U,
01545 } mtu_periph_space_t;
```

### 5.6.3.8 mtu\_tcr\_bits\_t

```
enum mtu_tcr_bits_t : uint8_t
```

Timer Control Register (TCR) bit field definitions.

The TCR register controls timer clock source selection, counting edge, and counter clear source. Each MTU channel has its own TCR register.

Register Bit Layout

```
* Bit 7 Bit 6 Bit 5 Bit 4 Bit 3 Bit 2 Bit 1 Bit 0
* -----
* | CCLR[2:0] | CKEG[1:0] | TPSC[2:0] |
* | Counter Clear | Clock Edge | Timer Prescaler |
* -----
*
```

Prescaler Values (TPSC)

| Value | Prescaler           | Frequency (120 MHz PCLKA) |
|-------|---------------------|---------------------------|
| 0x00  | $\text{PCLKA} / 1$  | 120 MHz                   |
| 0x01  | $\text{PCLKA} / 4$  | 30 MHz                    |
| 0x02  | $\text{PCLKA} / 16$ | 7.5 MHz                   |
| 0x03  | $\text{PCLKA} / 64$ | 1.875 MHz                 |

## Counter Clear Source (CCLR)

| Value | Source | Description                 |
|-------|--------|-----------------------------|
| 0x01  | TGRA   | Clear on TGRA compare match |
| 0x02  | TGRB   | Clear on TGRB compare match |
| 0x03  | Sync   | Synchronous clear (MTU3/4)  |

01184 k_mtu_tcr_tpsc_64 = 0x03,
01185
01186 /** @brief Clear counter on TGRA compare match */
01187 k_mtu_tcr_cclr_tgra = (k_mtu_bit_value_set « k_mtu_tcr_cclr_shift),
01188 } mtu_tcr_bits_t;

```

## 5.6.3.9 mtu\_tior\_bits\_t

```
enum mtu_tior_bits_t : uint8_t
```

Timer I/O Control Register (TIOR) bit field definitions.

The TIOR register controls the behavior of timer output pins on compare match events. TIORH controls TIOCA/TIOCB outputs, TIORL controls TIOCC/TIOCD.

Register Bit Layout (TIORH)

```

* Bit 7 Bit 6 Bit 5 Bit 4 Bit 3 Bit 2 Bit 1 Bit 0
* -----
* | IOB[3:0] | IOA[3:0] |
* | TIOCB Output Mode | TIOCA Output Mode |
* -----
*

```

Output Modes

| Value | Initial | On Match | PWM Application |
|-------|---------|----------|-----------------|
| 0x02  | Low     | High     | Active-high PWM |
| 0x05  | High    | Low      | Active-low PWM  |
| 0x03  | -       | Toggle   | 50% duty square |

PWM Configuration Example

```

// Configure TIOCA0 for active-high PWM output
mtu0()->tiorh = k_mtu_tior_init_low; // Low initially, high on match

```

```

## 5.6.3.10 mtu\_tmdr3\_bits\_t

```
enum mtu_tmdr3_bits_t : uint8_t
```

Timer Mode Register 3 (TMDR3) bits for MTU1/MTU2 32-bit cascaded mode.

TMDR3 register controls 32-bit cascaded counter operation for MTU1/MTU2 in phase counting mode. Available at offset 0x11 in [rx\\_mtu12\\_phase\\_regs\\_t](#).

Key features:

- LWA: Enables 32-bit cascaded counter (TCNTLW, TGRALW, TGRBLW)
- PHCKSEL: Selects phase counting clock edge (both edges vs single edge)

See also

RX72N Hardware Manual Section 24.2.25 (TMDR3 Register)

```

## 5.6.3.11 mtu\_tmdr\_bits\_t

```
enum mtu_tmdr_bits_t : uint8_t
```

Timer Mode Register (TMDR) bit field definitions.

The TMDR register selects the timer operating mode: normal operation, PWM generation, phase counting, or complementary PWM.

Register Bit Layout

```
* Bit 7 Bit 6 Bit 5 Bit 4 Bit 3 Bit 2 Bit 1 Bit 0
* -----
* | - | - | BFB | BFA | MD[3:0] |
* | Rsrvd | Rsrvd | BufferB | BufferA | Mode Select |
* -----
*
```

Operating Modes (MD[3:0

)]

| Value | Mode      | Description                        |
|-------|-----------|------------------------------------|
| 0x00  | Normal    | Free-running with compare match    |
| 0x02  | PWM 1     | TGRA=period, TGRB=duty             |
| 0x03  | PWM 2     | TGRC/D as buffer registers         |
| 0x04  | Phase 1   | Up/down on MTCLKA, dir from MTCLKB |
| 0x05  | Phase 2   | Up on MTCLKA, down on MTCLKB       |
| 0x06  | Phase 3   | Count on MTCLKA edges only         |
| 0x07  | Phase 4   | Count on MTCLKA and MTCLKB edges   |
| 0x0D  | Compl PWM | Complementary PWM (MTU3/4, 6/7)    |

Buffer Transfer Mode

When BFA or BFB is set, buffer registers (TGRC->TGRA, TGRD->TGRB) are automatically transferred on counter clear, enabling glitch-free duty cycle updates during PWM operation.

#### 5.6.3.12 mtu\_tstr\_bits\_t

```
enum mtu_tstr_bits_t : uint8_t
```

Timer Start Register A (TSTRA) bit definitions - controls MTU0-4, MTU8.

TSTRA (at 0x000C1280) controls the start/stop state of MTU channels 0-4 and 8. Setting a CSTn bit starts the corresponding timer; clearing it stops the timer.

Register Bit Layout (TSTRA)

```

* Bit 7 Bit 6 Bit 5 Bit 4 Bit 3 Bit 2 Bit 1 Bit 0
* -----
* | CST4 | CST3 | - | - | CST8 | CST2 | CST1 | CST0 |
* | MTU4 | MTU3 | Rsvd | Rsvd | MTU8 | MTU2 | MTU1 | MTU0 |
* -----
*

```

Synchronized Start Example

```

// Start MTU1 and MTU2 simultaneously for 32-bit cascaded mode
mtu_tstra()->tstr |= (k_mtu_tstr_cst1 | k_mtu_tstr_cst2);

// Stop all timers for configuration
mtu_tstra()->tstr = 0;

```

### 5.6.3.13 mtu\_tstrb\_bits\_t

```
enum mtu_tstrb_bits_t : uint8_t
```

Timer Start Register B (TSTRB) bit definitions - controls MTU6-7.

TSTRB (at 0x000C1A80) controls the start/stop state of MTU channels 6 and 7. These channels are typically used together for complementary PWM generation.

Register Bit Layout (TSTRB)

```

* Bit 7 Bit 6 Bit 5 Bit 4 Bit 3 Bit 2 Bit 1 Bit 0
* -----
* | CST7 | CST6 | - | - | - | - | - | - |
* | MTU7 | MTU6 | Reserved |
* -----
*

```

```

#### 5.6.3.14 rx\_mtu\_addresses\_t

enum [rx\\_mtu\\_addresses\\_t](#) : uintptr\_t

MTU3a peripheral base addresses (RX72N memory map Chapter 4).

Base addresses for all MTU3a timer channels. The MTU3a module occupies memory region 0x000C1200-0x000C1CFF in the RX72N peripheral address space.

Memory Map Overview

| * Address Range         | Channel | Notes                                |
|-------------------------|---------|--------------------------------------|
| * 0x000C1200-0x000C127F | MTU3/4  | Interleaved (complementary PWM pair) |
| * 0x000C1280-0x000C12FF | TSTRA   | Timer Start Register A (MTU0-4, 8)   |
| * 0x000C1300-0x000C137F | MTU0    | General-purpose timer                |
| * 0x000C1380-0x000C13FF | MTU1    | Phase counting capable               |
| * 0x000C1400-0x000C147F | MTU2    | Phase counting capable               |
| * 0x000C1600-0x000C16FF | MTU8    | 32-bit native counter                |
| * 0x000C1A00-0x000C1A7F | MTU6/7  | Interleaved (complementary PWM pair) |
| * 0x000C1A80-0x000C1AFF | TSTRB   | Timer Start Register B (MTU6-7)      |
| * 0x000C1C80-0x000C1CFF | MTU5    | Waveform generator (U/V/W phases)    |
| *                       |         |                                      |

Hardware Design Notes

- MTU3/MTU4 share base address 0x000C1200 (interleaved registers)
- MTU6/MTU7 share base address 0x000C1A00 (interleaved registers)
- Interleaving enables synchronized complementary PWM generation
- MTU1/MTU2 can cascade to form 32-bit counter (TCNTLW)

## Code Example

```
// Access MTU0 timer counter
volatile rx_mtu_channel_regs_t* mtu = mtu0();
uint16_t count = mtu->tcnt;

// Configure MTU0 for 20 kHz PWM
mtu->tcr = k_mtu_tcr_tpsc_1 | k_mtu_tcr_cclr_tgra; // PCLKA/1, clear on TGRA
mtu->tgra = 5999; // Period: 120 MHz / 6000 = 20 kHz
mtu->tgrb = 3000; // 50% duty cycle
```

## Enumerator

|                       |                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| k_mtu0_base_addr      | MTU0 base address (0x000C1300) - general purpose 16-bit timer.                                                                                                                                                                                |
| k_mtu1_base_addr      | MTU1 base address (0x000C1380) - 16-bit with phase counting, cascable to 32-bit.                                                                                                                                                              |
| k_mtu2_base_addr      | MTU2 base address (0x000C1400) - 16-bit with phase counting, cascable to 32-bit.                                                                                                                                                              |
| k_mtu3_base_addr      | MTU3 base address (0x000C1200) - complementary PWM pair with MTU4.                                                                                                                                                                            |
| k_mtu4_base_addr      | MTU4 base address (MTU3 + 1) - interleaved with MTU3. MTU4 registers are at odd offsets relative to MTU3 at even offsets. This interleaving enables synchronized complementary PWM operation.                                                 |
| k_mtu5u_base_addr     | MTU5U base address (0x000C1C80) - waveform generator U-phase.                                                                                                                                                                                 |
| k_mtu5v_base_addr     | MTU5V base address (0x000C1C90) - waveform generator V-phase.                                                                                                                                                                                 |
| k_mtu5w_base_addr     | MTU5W base address (0x000C1CA0) - waveform generator W-phase.                                                                                                                                                                                 |
| k_mtu6_base_addr      | MTU6 base address (0x000C1A00) - complementary PWM pair with MTU7. MTU6 and MTU7 share the same base address with interleaved registers.                                                                                                      |
| k_mtu7_base_addr      | MTU7 base address (MTU6 + 1) - interleaved with MTU6. MTU7 registers are at odd offsets relative to MTU6 at even offsets. This interleaving enables synchronized complementary PWM operation. (Manual: MTU7.TCR = 0x000C1A01 = MTU6 base + 1) |
| k_mtu8_base_addr      | MTU8 base address (0x000C1600) - native 32-bit counter.                                                                                                                                                                                       |
| k_mtu_tstra_base_addr | TSTRA base address (0x000C1280) - timer start control for MTU0-4, MTU8.                                                                                                                                                                       |

```

## 5.6.4 Function Documentation

### 5.6.4.1 mtu0()

```
volatile rx_mtu_channel_regs_t * mtu0 (
 void) [inline], [static]
```

Get pointer to MTU0 registers.

Returns a volatile pointer to MTU0's register structure at base address 0x000C1300. MTU0 is a general-purpose 16-bit timer commonly used for PWM generation or interval timing.

Returns

Volatile pointer to MTU0 register structure

### Example

```

// Read MTU0 counter value
uint16_t count = mtu0()->tcnt;

// Configure MTU0 for 20 kHz PWM
mtu0()->tcr = k_mtu_tcr_tpsc_1 | k_mtu_tcr_cclr_tgra;
mtu0()->tgra = 5999; // Period: 120 MHz / 6000 = 20 kHz

```

Note

Thread-safe: returns constant hardware address

Here is the caller graph for this function:

#### 5.6.4.2 mtu1()

```
volatile rx_mtu_channel_regs_t * mtu1 (
 void) [inline], [static]
```

Get pointer to MTU1 registers (16-bit mode).

Returns a volatile pointer to MTU1's standard 16-bit register structure. For 32-bit cascaded phase counting mode, use [mtu1\\_phase\(\)](#) instead.

Returns

Volatile pointer to MTU1 register structure

See also

[mtu1\\_phase\(\)](#) for 32-bit cascaded phase counting

[rx\\_mtu\\_channel\\_regs\\_t](#) for register layout

Definition at line 928 of file [rx72n\\_mtu\\_regs.h](#).

```
00929 {

Here is the caller graph for this function:

#### 5.6.4.3 mtu1`phase()

```
volatile rx_mtu12_phase_regs_t * mtu1_phase (
 void) [inline], [static]
```

Get pointer to MTU1 extended registers for 32-bit phase counting mode.

Provides access to MTU1's extended register set including TMDR3 and 32-bit cascaded counter registers (TCNTLW, TGRALW, TGRBLW). Use this accessor when configuring or reading 32-bit cascaded phase counting mode.

For standard 16-bit phase counting, use [mtu1\(\)](#) instead.

Returns

Volatile pointer to MTU1 extended register structure

```
00971 {
00972 return (volatile rx_mtu12_phase_regs_t*)k_mtu1_base_addr;
00973 }
```

References [k\\_mtu1\\_base\\_addr](#).

#### 5.6.4.4 mtu2()

```
volatile rx_mtu_channel_regs_t * mtu2 (
 void) [inline], [static]
```

Get pointer to MTU2 registers (16-bit mode).

Returns a volatile pointer to MTU2's standard 16-bit register structure. For 32-bit cascaded phase counting mode, use [mtu2\\_phase\(\)](#) instead.

## Returns

Volatile pointer to MTU2 register structure

## See also

[mtu2\\_phase\(\)](#) for 32-bit cascaded phase counting

00949 {
00950 return (volatile rx_mtu_channel_regs_t*)k_mtu2_base_addr;
00951 }
```

References [k\\_mtu2\\_base\\_addr](#).

Referenced by [internal\\_get\\_mtu\\_base\(\)](#).

Here is the caller graph for this function:

## 5.6.4.5 mtu2\_phase()

```
volatile rx_mtu12_phase_regs_t * mtu2_phase (
 void) [inline], [static]
```

Get pointer to MTU2 extended registers for 32-bit phase counting mode.

Provides access to MTU2's extended register set including TMDR3 and 32-bit cascaded counter registers (TCNTLW, TGRALW, TGRBLW). Use this accessor when configuring or reading 32-bit cascaded phase counting mode.

For standard 16-bit phase counting, use [mtu2\(\)](#) instead.

## Returns

Volatile pointer to MTU2 extended register structure

## See also

[rx\\_mtu12\\_phase\\_regs\\_t](#) for complete register map

```
00992 {
00993 return (volatile rx_mtu12_phase_regs_t*)k_mtu2_base_addr;
00994 }
```

References [k\\_mtu2\\_base\\_addr](#).

#### 5.6.4.6 mtu3()

```
volatile rx_mtu3_channel_regs_t * mtu3 (
 void) [inline], [static]
```

Get pointer to MTU3 registers via [rx\\_mtu3\\_channel\\_regs\\_t](#) struct.

Returns a pointer to MTU3's register space cast to [rx\\_mtu3\\_channel\\_regs\\_t](#). The struct has been carefully padded to match the actual hardware layout verified against the RX72N Ch 5 I/O Register Address Table.

MTU3 and MTU4 registers are interleaved at 0x000C1200: MTU3 at 0x000C1200, MTU4 at 0x000C1201, with shared MTU3/4 registers interspersed. The struct fields (tcr, tmdr1, tiorh, tiorl, tier, tcnt, tgra, tgrb, tgrc, tgrd, tsr, tbtm, tcr2, tgre) are placed at the correct byte offsets for MTU3. The gap bytes in the struct are reserved/MTU4/shared-register space.

#### Warning

Do NOT use this pointer for MTU4 register access. MTU4 registers are at different offsets relative to the MTU4 base (0x000C1201). Access MTU4 registers using the individual address constants or by computing addresses manually from `k_mtu4_base_addr`.

#### Returns

Volatile pointer to MTU3 register structure (base 0x000C1200)

#### See also

[rx\\_mtu3\\_channel\\_regs\\_t](#) for complete register layout with addresses  
 RX72N Hardware Manual Ch 5 I/O Register Address Table (MTU3a)

Definition at line 1020 of file [rx72n\\_mtu\\_regs.h](#).

```
01021 {
01022 return (volatile rx_mtu3_channel_regs_t*)k_mtu3_base_addr;
01023 }
```

References [k\\_mtu3\\_base\\_addr](#).

#### 5.6.4.7 mtu4()

```
volatile void * mtu4 (
 void) [inline], [static]
```

Get raw base address pointer for MTU4 register access.

Returns the MTU4 base address (0x000C1201) as a void pointer. MTU4 registers are at DIFFERENT relative offsets than MTU3 registers, so the [rx\\_mtu3\\_channel\\_regs\\_t](#) struct CANNOT be used for MTU4.

MTU4 register addresses from the RX72N Ch 5 I/O Address Table:

- MTU4.TCR = 0x000C1201 (`k_mtu4_base_addr + 0x00`)
- MTU4.TMDR1 = 0x000C1203 (`k_mtu4_base_addr + 0x02`)

- MTU4.TIORH = 0x000C1206 (k\_mtu4\_base\_addr + 0x05) – NOTE: +0x05, not +0x04
- MTU4.TIORL = 0x000C1207 (k\_mtu4\_base\_addr + 0x06)
- MTU4.TIER = 0x000C1209 (k\_mtu4\_base\_addr + 0x08)
- MTU4.TCNT = 0x000C1212 (k\_mtu4\_base\_addr + 0x11) – NOTE: odd address
- MTU4.TGRA = 0x000C121C (k\_mtu4\_base\_addr + 0x1B)
- MTU4.TGRB = 0x000C121E (k\_mtu4\_base\_addr + 0x1D)
- MTU4.TGRC = 0x000C1228 (k\_mtu4\_base\_addr + 0x27)
- MTU4.TGRD = 0x000C122A (k\_mtu4\_base\_addr + 0x29)
- MTU4.TSR = 0x000C122D (k\_mtu4\_base\_addr + 0x2C)
- MTU4.TBTM = 0x000C1239 (k\_mtu4\_base\_addr + 0x38)
- MTU4.TCR2 = 0x000C124D (k\_mtu4\_base\_addr + 0x4C)
- MTU4.TGRE = 0x000C1274 (k\_mtu4\_base\_addr + 0x73)
- MTU4.TGRF = 0x000C1276 (k\_mtu4\_base\_addr + 0x75) – MTU3 has no TGRF

Access MTU4 registers by casting the returned pointer to the appropriate volatile integer pointer and applying the correct offset, e.g.: (volatile uint8\_t)((uintptr\_t)mtu4() + 0x05U) = value; // MTU4.TIORH

Returns

Volatile void pointer to MTU4 base address (0x000C1201)

See also

RX72N Hardware Manual Ch 5 I/O Register Address Table (MTU3a)

Definition at line 1058 of file rx72n\_mtu\_regs.h.

```
01059 {
01060 return (volatile void*)k_mtu4_base_addr;
01061 }
```

References [k\\_mtu4\\_base\\_addr](#).

#### 5.6.4.8 mtu6()

```
volatile rx_mtu3_channel_regs_t * mtu6 (
 void) [inline], [static]
```

Get pointer to MTU6 registers (interleaved layout, identical to MTU3).

MTU6/MTU7 registers are interleaved at 0x000C1A00 in the same pattern as MTU3/MTU4 at 0x000C1200. MTU6 registers are at even offsets; MTU7 registers are at odd offsets. Use [rx\\_mtu3\\_channel\\_regs\\_t](#) to access MTU6 fields at their correct byte offsets (TCR+=+0x00, TMDR1+=+0x02, TIORH+=+0x04, etc.).

## Warning

Do NOT cast this pointer to `rx_mtu_channel_regs_t` – that struct assumes consecutive layout (TMDR at +0x01) which is wrong for MTU6.

## Returns

Volatile pointer to MTU6 register structure (interleaved layout)

## See also

[rx\\_mtu3\\_channel\\_regs\\_t](#) for register layout and field offsets  
[mtu7\(\)](#) for raw MTU7 base pointer (void\*)

Definition at line 1080 of file `rx72n_mtu_regs.h`.

```
01081 {
01082 return (volatile rx_mtu3_channel_regs_t*)k_mtu6_base_addr;
01083 }
```

References [k\\_mtu6\\_base\\_addr](#).

## 5.6.4.9 mtu7()

```
volatile void * mtu7 (
 void) [inline], [static]
```

Get raw base address pointer for MTU7 register access.

Returns the MTU7 base address (`k_mtu6_base_addr + 1 = 0x000C1A01`) as a void pointer. MTU7 registers are at DIFFERENT relative offsets than MTU6 registers (same situation as MTU4 relative to MTU3), so no struct type can be directly applied. Access MTU7 registers by computing addresses manually from `k_mtu7_base_addr` using the Ch 5 I/O Address Table.

## Returns

Volatile void pointer to MTU7 base address (0x000C1A01)

## See also

[mtu6\(\)](#) for MTU6 access via [rx\\_mtu3\\_channel\\_regs\\_t](#)  
 RX72N Hardware Manual Ch 5 I/O Register Address Table (MTU3a)

Definition at line 1100 of file `rx72n_mtu_regs.h`.

```
01101 {
01102 return (volatile void*)k_mtu7_base_addr;
01103 }
```

References [k\\_mtu7\\_base\\_addr](#).

5.6.4.10 `mtu_tstra()`

```
volatile rx_mtu_tstr_regs_t * mtu_tstra (
 void) [inline], [static]
```

Get pointer to MTU TSTRA registers (MTU0-4, MTU8).

Returns

Volatile pointer to MTU TSTRA register structure

Definition at line 1111 of file `rx72n_mtu_regs.h`.

```
01112 {
01113 return (volatile rx_mtu_tstr_regs_t*)k_mtu_tstra_base_addr;
01114 }
```

References `k_mtu_tstra_base_addr`.

Referenced by `rx_mtu_start()`, and `rx_mtu_stop()`.

Here is the caller graph for this function:

5.6.4.11 `mtu_tstrb()`

```
volatile rx_mtu_tstr_regs_t * mtu_tstrb (
 void) [inline], [static]
```

Get pointer to MTU TSTRB registers (MTU6-7).

Returns

Volatile pointer to MTU TSTRB register structure

Definition at line 1121 of file `rx72n_mtu_regs.h`.

```
01122 {
01123 return (volatile rx_mtu_tstr_regs_t*)k_mtu_tstrb_base_addr;
01124 }
```

References `k_mtu_tstrb_base_addr`.

Referenced by `rx_mtu_start()`, and `rx_mtu_stop()`.

Here is the caller graph for this function:

## 5.7 PORT Register Definitions

### Data Structures

- struct `rx_port_regs_t`  
Port Register Map providing logical per-port view of RX72N GPIO.

### Enumerations

- enum `rx_port_reg_bases_t` : `uintptr_t` {  
`k_port_pdr_base` = 0x0008C000 , `k_port_podr_base` = 0x0008C020 , `k_port_pidr_base` = 0x0008C040 , `k_port_pmr_base` = 0x0008C060 ,  
`k_port_odr0_base` = 0x0008C080 , `k_port_pcr_base` = 0x0008C0C0 , `k_port_dscr_base` = 0x0008C0E0 , `k_port_dscr2_base` = 0x0008C128 }  
PORT register block base addresses (organized by register type).
- enum `rx_port_offsets_t` : `uint8_t` {  
`k_port_offset_0` = 0x00 , `k_port_offset_1` = 0x01 , `k_port_offset_2` = 0x02 , `k_port_offset_3` = 0x03 ,  
`k_port_offset_4` = 0x04 , `k_port_offset_5` = 0x05 , `k_port_offset_6` = 0x06 , `k_port_offset_7` = 0x07 ,  
`k_port_offset_8` = 0x08 , `k_port_offset_9` = 0x09 , `k_port_offset_a` = 0x0A , `k_port_offset_b` = 0x0B ,  
`k_port_offset_c` = 0x0C , `k_port_offset_d` = 0x0D , `k_port_offset_e` = 0x0E , `k_port_offset_f` = 0x0F ,  
`k_port_offset_j` = 0x12 }  
Port number offsets for register access (144-pin LQFP).

### Functions

- static volatile `rx_port_regs_t * port0` (void)  
Get pointer to PORT0 registers.
- static volatile `rx_port_regs_t * port1` (void)  
Get pointer to PORT1 registers.
- static volatile `rx_port_regs_t * port2` (void)  
Get pointer to PORT2 registers.
- static volatile `rx_port_regs_t * port3` (void)  
Get pointer to PORT3 registers.
- static volatile `rx_port_regs_t * port4` (void)  
Get pointer to PORT4 registers.
- static volatile `rx_port_regs_t * port5` (void)  
Get pointer to PORT5 registers.
- static volatile `rx_port_regs_t * port6` (void)  
Get pointer to PORT6 registers.
- static volatile `rx_port_regs_t * port7` (void)  
Get pointer to PORT7 registers.
- static volatile `rx_port_regs_t * port8` (void)  
Get pointer to PORT8 registers.
- static volatile `rx_port_regs_t * port9` (void)  
Get pointer to PORT9 registers.
- static volatile `rx_port_regs_t * porta` (void)  
Get pointer to PORTA registers.

- static volatile `rx_port_regs_t * portb` (void)  
Get pointer to PORTB registers.
- static volatile `rx_port_regs_t * portc` (void)  
Get pointer to PORTC registers.
- static volatile `rx_port_regs_t * portd` (void)  
Get pointer to PORTD registers.
- static volatile `rx_port_regs_t * porte` (void)  
Get pointer to PORTE registers.
- static volatile `rx_port_regs_t * portf` (void)  
Get pointer to PORTF registers.
- static volatile `rx_port_regs_t * portj` (void)  
Get pointer to PORTJ registers.
- static volatile `uint16_t * port0_odr` (void)  
Get pointer to PORT0 ODR register.
- static volatile `uint16_t * port1_odr` (void)  
Get pointer to PORT1 ODR register.
- static volatile `uint16_t * port2_odr` (void)  
Get pointer to PORT2 ODR register.
- static volatile `uint16_t * port3_odr` (void)  
Get pointer to PORT3 ODR register.
- static volatile `uint16_t * port4_odr` (void)  
Get pointer to PORT4 ODR register.
- static volatile `uint16_t * port5_odr` (void)  
Get pointer to PORT5 ODR register.
- static volatile `uint16_t * port6_odr` (void)  
Get pointer to PORT6 ODR register.
- static volatile `uint16_t * port7_odr` (void)  
Get pointer to PORT7 ODR register.
- static volatile `uint16_t * port8_odr` (void)  
Get pointer to PORT8 ODR register.
- static volatile `uint16_t * port9_odr` (void)  
Get pointer to PORT9 ODR register.
- static volatile `uint16_t * porta_odr` (void)  
Get pointer to PORTA ODR register.
- static volatile `uint16_t * portb_odr` (void)  
Get pointer to PORTB ODR register.
- static volatile `uint16_t * portc_odr` (void)  
Get pointer to PORTC ODR register.
- static volatile `uint16_t * portd_odr` (void)  
Get pointer to PORTD ODR register.
- static volatile `uint16_t * porte_odr` (void)  
Get pointer to PORTE ODR register.
- static volatile `uint16_t * portf_odr` (void)  
Get pointer to PORTF ODR register.
- static volatile `uint16_t * portj_odr` (void)  
Get pointer to PORTJ ODR register.

### 5.7.1 Detailed Description

### 5.7.2 Data Structure Documentation

#### 5.7.2.1 struct rx'port'regs't

Port Register Map providing logical per-port view of RX72N GPIO.

This structure provides a convenient PORT-centric view of the GPIO registers, abstracting away the hardware's type-grouped layout. Padding bytes ensure correct alignment between register types.

Register Memory Layout (297 bytes total per port view)

| * Offset | Size | Register | Description                                    |
|----------|------|----------|------------------------------------------------|
| * 0x00   | 1    | PDR      | Port Direction (0=input, 1=output)             |
| * 0x01   | 31   | [pad]    | Reserved padding to PODR                       |
| * 0x20   | 1    | PODR     | Port Output Data (0=low, 1=high)               |
| * 0x21   | 31   | [pad]    | Reserved padding to PIDR                       |
| * 0x40   | 1    | PIDR     | Port Input Data (read-only, current pin level) |
| * 0x41   | 31   | [pad]    | Reserved padding to PMR                        |
| * 0x60   | 1    | PMR      | Port Mode (0=GPIO, 1=peripheral function)      |
| * 0x61   | 95   | [pad]    | Reserved (includes ODR space, see note below)  |
| * 0xC0   | 1    | PCR      | Pull-up Control (0=disabled, 1=enabled)        |
| * 0xC1   | 31   | [pad]    | Reserved padding to DSCR                       |
| * 0xE0   | 1    | DSCR     | Drive Capacity (0=normal, 1=high drive)        |
| * 0xE1   | 71   | [pad]    | Reserved padding to DSCR2                      |
| * 0x128  | 1    | DSCR2    | Drive Capacity 2 (enhanced high drive)         |
| *        |      |          |                                                |

Note

ODR (Open Drain Control) registers are NOT part of this structure. They use word addressing and are accessed via separate port\*\_odr() functions at hardware addresses: 0x0008C080 + (port\_offset \* 2)

#### GPIO Configuration Sequence

Typical GPIO output configuration sequence:

1. Set PMR = 0 (GPIO mode, not peripheral)
2. Set PDR = 1 (output direction)
3. Set PODR = desired output level
4. Optionally set DSCR = 1 for high drive current

Typical GPIO input configuration sequence:

1. Set PMR = 0 (GPIO mode)
2. Set PDR = 0 (input direction)
3. Optionally set PCR = 1 for internal pull-up
4. Read PIDR for current pin state

## LED Blink Example

```
// Configure PD0 as output and blink LED
volatile rx_port_regs_t* pd = portd();

pd->pmr &= ~(1 << 0); // GPIO mode
pd->pdr |= (1 << 0); // Output direction

while (1) {
 pd->podr ^= (1 << 0); // Toggle LED
 delay_ms(500);
}
```

## Button Read Example

```
// Configure PA0 as input with pull-up and read button
volatile rx_port_regs_t* pa = porta();

pa->pmr &= ~(1 << 0); // GPIO mode
pa->pdr &= ~(1 << 0); // Input direction
pa->pcr |= (1 << 0); // Enable pull-up (button connects to GND)

bool pressed = ((pa->pidr & (1 << 0)) == 0); // Active-low
```

## Invariant

Structure size must be exactly 297 bytes (0x129)  
 All register offsets must match hardware layout exactly  
 Structure must be packed to ensure correct padding sizes

## Note

Uses attribute((packed)) to prevent compiler padding optimizations

## Warning

This structure assumes PORT0 padding layout (offset=0x00). The type-grouped hardware layout places ODR at varying struct offsets for different ports (0x80 + port\_offset\*2). ODR is accessed via separate port\*\_odr() functions to ensure correct word addressing.

Do not use sizeof() for port address calculations; use offset enum

## Note

PORT3 lacks DSCR (has only DSCR2).  
 PORT4 lacks both DSCR and DSCR2 (hardware limitation).  
 All other ports (0-2, 5, A-E, J) have both DSCR and DSCR2.

| volatile uint8_t | podr  | <p>Port Output Data Register (PODR) - +0x20.<br/>Sets output level: 0 = low, 1 = high.</p> <p>Note</p> <p>Only effective when PDR bit = 1 (output direction).</p>                                                                                                                                                                     |

### 5.7.3 Enumeration Type Documentation

#### 5.7.3.1 rx\_port\_offsets\_t

```
enum rx_port_offsets_t : uint8_t
```

Port number offsets for register access (144-pin LFQFP).

Offset values to add to register base addresses for accessing specific ports. The 144-pin LFQFP package has broader port availability compared to the 144-pin package. Ports G, H, K, L, M, N, Q are not bonded out.

#### Available Pins by Port (144-pin LFQFP)

| Port | Offset | Available Pins    | Notes                       |
|------|--------|-------------------|-----------------------------|
| 0    | 0x00   | P00-P03, P05, P07 | 6 pins (no P04, P06)        |
| 1    | 0x01   | P12-P17           | 6 pins (no P10, P11)        |
| 2    | 0x02   | P20-P27           | Full 8 pins                 |
| 3    | 0x03   | P30-P37           | Full 8 pins, P35 input-only |
| 4    | 0x04   | P40-P47           | Full 8 pins                 |
| 5    | 0x05   | P50-P56           | 7 pins (no P57)             |
| 6    | 0x06   | P60-P67           | Full 8 pins                 |
| 7    | 0x07   | P70-P77           | Full 8 pins                 |
| 8    | 0x08   | P80-P83, P86-P87  | 6 pins (no P84, P85)        |
| 9    | 0x09   | P90-P93           | 4 pins (no P94-P97)         |
| A    | 0x0A   | PA0-PA7           | Full 8 pins                 |
| B    | 0x0B   | PB0-PB7           | Full 8 pins                 |
| C    | 0x0C   | PC0-PC7           | Full 8 pins                 |
| D    | 0x0D   | PD0-PD7           | Full 8 pins                 |
| E    | 0x0E   | PE0-PE7           | Full 8 pins                 |
| F    | 0x0F   | PF5               | 1 pin only                  |
| J    | 0x12   | PJ3, PJ5          | 2 pins only                 |

#### Usage Example

```
// Calculate PORTB PDR address (uintptr_t preserves full pointer width on all hosts)
uintptr_t portb_pdr_addr = k_port_pdr_base + k_port_offset_b; // 0x0008C00B

// Calculate PORTD PODR address
uintptr_t portd_podr_addr = k_port_podr_base + k_port_offset_d; // 0x0008C02D
```

```

### 5.7.3.2 rx\_port\_reg\_bases\_t

```
enum rx_port_reg_bases_t : uintptr_t
```

PORT register block base addresses (organized by register type).

The RX72N organizes port registers by type rather than by port number. All PDR registers are contiguous, all PODR registers are contiguous, etc. This enum provides base addresses for each register type block.

### Memory Map Overview

| * Address Range         | Register Type | Description                          |
|-------------------------|---------------|--------------------------------------|
| * -----                 |               |                                      |
| * 0x0008C000-0x0008C017 | PDR[]         | Port Direction Registers             |
| * 0x0008C020-0x0008C037 | PODR[]        | Port Output Data Registers           |
| * 0x0008C040-0x0008C057 | PIDR[]        | Port Input Data Registers            |
| * 0x0008C060-0x0008C077 | PMR[]         | Port Mode Registers                  |
| * 0x0008C080-0x0008C0B7 | ODR0/ODR1[]   | Open Drain Control (16-bit per port) |
| * 0x0008C0C0-0x0008C0D7 | PCR[]         | Pull-up Control Registers            |
| * 0x0008C0E0-0x0008C0F7 | DSCR[]        | Drive Capacity Registers             |
| * 0x0008C128-0x0008C13F | DSCR2[]       | Drive Capacity 2 Registers           |
| *                       |               |                                      |

### Register Access Pattern

To access a specific port's register, add the port offset to the base:

- PORT0.PDR = k\_port\_pdr\_base + k\_port\_offset\_0 = 0x0008C000
- PORTB.PDR = k\_port\_pdr\_base + k\_port\_offset\_b = 0x0008C00B
- PORTD.PODR = k\_port\_podr\_base + k\_port\_offset\_d = 0x0008C02D

## Enumerator

|                   |                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| k_port_pdr_base   | PDR (Port Direction Register) base address. All PDRn registers at 0x0008C000 + port_offset. PDR bit = 0: Input, PDR bit = 1: Output.                                                                                                                                          |
| k_port_podr_base  | PODR (Port Output Data Register) base address. All PODRn registers at 0x0008C020 + port_offset. PODR bit = 0: Output low, PODR bit = 1: Output high.                                                                                                                          |
| k_port_pidr_base  | PIDR (Port Input Data Register) base address. All PIDRn registers at 0x0008C040 + port_offset. Read-only. Returns current pin logic level.                                                                                                                                    |
| k_port_pmr_base   | PMR (Port Mode Register) base address. All PMRn registers at 0x0008C060 + port_offset. PMR bit = 0: GPIO mode, PMR bit = 1: Peripheral function.                                                                                                                              |
| k_port_odr0_base  | <p>ODR0 (Open Drain Control 0) base address. ODR0/ODR1 form a 16-bit register per port at 0x0008C080 + 2*port_offset. ODR bit = 0: CMOS output, ODR bit = 1: Open-drain output.</p> <p>Note</p> <p>ODR1 immediately follows ODR0; accessed as 16-bit odr field in struct.</p> |
| k_port_pcr_base   | PCR (Pull-up Control Register) base address. All PCRN registers at 0x0008C0C0 + port_offset. PCR bit = 0: Pull-up disabled, PCR bit = 1: Pull-up enabled.                                                                                                                     |
| k_port_dscr_base  | DSCR (Drive Capacity Control Register) base address. All DSCRn registers at 0x0008C0E0 + port_offset. DSCR bit = 0: Normal drive, DSCR bit = 1: High drive.                                                                                                                   |
| k_port_dscr2_base | <p>DSCR2 (Drive Capacity Control Register 2) base address. All DSCR2n registers at 0x0008C128 + port_offset. DSCR2 bit = 0: Normal drive (same as DSCR). DSCR2 bit = 1: Enhanced high drive capacity.</p> <p>Note</p> <p>Not available on PORT4.</p>                          |

## 5.7.4 Function Documentation

### 5.7.4.1 port0()

```
volatile rx_port_regs_t * port0 (
 void) [inline], [static]
```

Get pointer to PORT0 registers.

Returns a volatile pointer to PORT0's register structure. PORT0 has P00-P03, P05, P07 available on the 144-pin LFQFP package (6 pins).

Returns

Volatile pointer to PORT0 register structure

Register Addresses

- PDR: 0x0008C000
- PODR: 0x0008C020
- PIDR: 0x0008C040
- PMR: 0x0008C060

Available Pins (144-pin)

P00-P03, P05, P07 (6 pins)

Note

Thread-safe: returns constant hardware address

See also

#### 5.7.4.2 port0`odr()

```
volatile uint16_t * port0_odr (
 void) [inline], [static]
```

Get pointer to PORT0 ODR register.

Returns

Volatile pointer to 16-bit ODR register (combines ODR0+ODR1)

Note

PORT0.ODR = 0x0008C080

Definition at line 826 of file [rx72n\\_port\\_regs.h](#).

```
00827 {
00828 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_0 * 2));
00829 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_0](#).

### 5.7.4.3 port1()

```
volatile rx_port_regs_t * port1 (
 void) [inline], [static]
```

Get pointer to PORT1 registers.

Returns

Volatile pointer to PORT1 register structure

Note

PORT1 PDR = 0x0008C001, PODR = 0x0008C021, PIDR = 0x0008C041

144-pin: Only P12-P17 available

Definition at line 619 of file [rx72n\\_port\\_regs.h](#).

```
00620 {
00621 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_1);
00622 }
```

References [k\\_port\\_offset\\_1](#), and [k\\_port\\_pdr\\_base](#).

Here is the caller graph for this function:

## 5.7.4.4 port1\_odr()

```
volatile uint16_t * port1_odr (
 void) [inline], [static]
```

Get pointer to PORT1 ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORT1.ODR = 0x0008C082 (word addressing: base + offset\*2)

Definition at line 836 of file [rx72n\\_port\\_regs.h](#).

```
00837 {
00838 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_1 * 2));
00839 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_1](#).

## 5.7.4.5 port2()

```
volatile rx_port_regs_t * port2 (
 void) [inline], [static]
```

Get pointer to PORT2 registers.

Returns

Volatile pointer to PORT2 register structure

Note

PORT2 PDR = 0x0008C002, PODR = 0x0008C022, PIDR = 0x0008C042  
144-pin: P20-P27 available

Definition at line 630 of file [rx72n\\_port\\_regs.h](#).

```
00631 {
00632 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_2);
00633 }
```

References [k\\_port\\_offset\\_2](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

#### 5.7.4.6 port2odr()

```
volatile uint16_t * port2_odr (
 void) [inline], [static]
```

Get pointer to PORT2 ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORT2.ODR = 0x0008C084

Definition at line 846 of file [rx72n\\_port\\_regs.h](#).

```
00847 {
00848 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_2 * 2));
00849 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_2](#).

## 5.7.4.7 port3()

```
volatile rx_port_regs_t * port3 (
 void) [inline], [static]
```

Get pointer to PORT3 registers.

Returns

Volatile pointer to PORT3 register structure

Note

PORT3 PDR = 0x0008C003, PODR = 0x0008C023, PIDR = 0x0008C043  
 144-pin: P30-P37 available (P35 is input-only)

Definition at line 642 of file rx72n\_port\_regs.h.

```
00643 {
00644 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_3);
00645 }
```

References [k\\_port\\_offset\\_3](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

#### 5.7.4.8 port3odr()

```
volatile uint16_t * port3odr (
 void) [inline], [static]
```

Get pointer to PORT3 ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORT3.ODR = 0x0008C086

Definition at line 856 of file [rx72n\\_port\\_regs.h](#).

```
00857 {
00858 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_3 * 2));
00859 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_3](#).

#### 5.7.4.9 port4()

```
volatile rx_port_regs_t * port4 (
 void) [inline], [static]
```

Get pointer to PORT4 registers.

Returns

Volatile pointer to PORT4 register structure

Note

PORT4 PDR = 0x0008C004, PODR = 0x0008C024, PIDR = 0x0008C044  
144-pin: P40-P47 available

Definition at line 655 of file [rx72n\\_port\\_regs.h](#).

```
00656 {
00657 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_4);
00658 }
```

References [k\\_port\\_offset\\_4](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

## 5.7.4.11 port5()

```
volatile rx_port_regs_t * port5 (
 void) [inline], [static]
```

Get pointer to PORT5 registers.

Returns

Volatile pointer to PORT5 register structure

Note

PORT5 PDR = 0x0008C005, PODR = 0x0008C025, PIDR = 0x0008C045  
144-pin: P50-P56 available (7 pins)

Definition at line 668 of file rx72n\_port\_regs.h.

```
00669 {
00670 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_5);
00671 }
```

References [k\\_port\\_offset\\_5](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

5.7.4.12 `port5_odr()`

```
volatile uint16_t * port5_odr (
 void) [inline], [static]
```

Get pointer to PORT5 ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORT5.ODR = 0x0008C08A

Definition at line 876 of file [rx72n\\_port\\_regs.h](#).

```
00877 {
00878 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_5 * 2));
00879 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_5](#).

5.7.4.13 `port6()`

```
volatile rx_port_regs_t * port6 (
 void) [inline], [static]
```

Get pointer to PORT6 registers.

Returns

Volatile pointer to PORT6 register structure

Note

PORT6 PDR = 0x0008C006, PODR = 0x0008C026, PIDR = 0x0008C046  
144-pin: P60-P67 available (8 pins)

Definition at line 681 of file [rx72n\\_port\\_regs.h](#).

```
00682 {
00683 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_6);
00684 }
```

References [k\\_port\\_offset\\_6](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_host\\_irq\\_assert\(\)](#), [rx\\_host\\_irq\\_deassert\(\)](#), [rx\\_host\\_irq\\_deinit\(\)](#), [rx\\_host\\_irq\\_init\(\)](#), [rx\\_host\\_irq\\_is\\_asserted\(\)](#), and [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

#### 5.7.4.14 port6 odr()

```
volatile uint16_t * port6_odr (
 void) [inline], [static]
```

Get pointer to PORT6 ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORT6.ODR = 0x0008C08C (offset 0x06 \* 2)

Definition at line 886 of file [rx72n\\_port\\_regs.h](#).

```
00887 {
00888 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_6 * 2));
00889 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_6](#).

## 5.7.4.15 port7()

```
volatile rx_port_regs_t * port7 (
 void) [inline], [static]
```

Get pointer to PORT7 registers.

Returns

Volatile pointer to PORT7 register structure

Note

PORT7 PDR = 0x0008C007, PODR = 0x0008C027, PIDR = 0x0008C047  
144-pin: P70-P77 available (8 pins)

Definition at line 694 of file rx72n\_port\_regs.h.

```
00695 {
00696 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_7);
00697 }
```

References [k\\_port\\_offset\\_7](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

#### 5.7.4.16 port7\_odr()

```
volatile uint16_t * port7_odr (
 void) [inline], [static]
```

Get pointer to PORT7 ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORT7.ODR = 0x0008C08E (offset 0x07 \* 2)

Definition at line 896 of file [rx72n\\_port\\_regs.h](#).

```
00897 {
00898 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_7 * 2));
00899 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_7](#).

#### 5.7.4.17 port8()

```
volatile rx_port_regs_t * port8 (
 void) [inline], [static]
```

Get pointer to PORT8 registers.

Returns

Volatile pointer to PORT8 register structure

Note

PORT8 PDR = 0x0008C008, PODR = 0x0008C028, PIDR = 0x0008C048  
144-pin: P80-P83, P86-P87 available (6 pins)

Definition at line 707 of file [rx72n\\_port\\_regs.h](#).

```
00708 {
00709 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_8);
00710 }
```

References [k\\_port\\_offset\\_8](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

#### 5.7.4.18 port8 odr()

```
volatile uint16_t * port8_odr (
 void) [inline], [static]
```

Get pointer to PORT8 ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORT8.ODR = 0x0008C090 (offset 0x08 \* 2)

Definition at line 906 of file [rx72n\\_port\\_regs.h](#).

```
00907 {
00908 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_8 * 2));
00909 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_8](#).

### 5.7.4.19 port9()

```
volatile rx_port_regs_t * port9 (
 void) [inline], [static]
```

Get pointer to PORT9 registers.

Returns

Volatile pointer to PORT9 register structure

Note

PORT9 PDR = 0x0008C009, PODR = 0x0008C029, PIDR = 0x0008C049

144-pin: P90-P93 available (4 pins)

Definition at line 720 of file [rx72n\\_port\\_regs.h](#).

```
00721 {
00722 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_9);
00723 }
```

References [k\\_port\\_offset\\_9](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

## 5.7.4.20 port9odr()

```
volatile uint16_t * port9odr (
 void) [inline], [static]
```

Get pointer to PORT9 ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORT9.ODR = 0x0008C092 (offset 0x09 \* 2)

Definition at line 916 of file [rx72n\\_port\\_regs.h](#).

```
00917 {
00918 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_9 * 2));
00919 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_9](#).

## 5.7.4.21 porta()

```
volatile rx_port_regs_t * porta (
 void) [inline], [static]
```

Get pointer to PORTA registers.

Returns

Volatile pointer to PORTA register structure

Note

PORTA PDR = 0x0008C00A, PODR = 0x0008C02A, PIDR = 0x0008C04A  
144-pin: PA0-PA7 available

Definition at line 732 of file [rx72n\\_port\\_regs.h](#).

```
00733 {
00734 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_a);
00735 }
```

References [k\\_port\\_offset\\_a](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

#### 5.7.4.22 `portaodr()`

```
volatile uint16_t * portaodr (
 void) [inline], [static]
```

Get pointer to PORTA ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

$\text{PORTA.ODR} = 0x0008C094$  (offset  $0x0A * 2$ )

Definition at line 926 of file `rx72n_port_regs.h`.

```
00927 {
00928 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_a * 2));
00929 }
```

References `k_port_odr0_base`, and `k_port_offset_a`.

## 5.7.4.23 portb()

```
volatile rx_port_regs_t * portb (
 void) [inline], [static]
```

Get pointer to PORTB registers.

Returns

Volatile pointer to PORTB register structure

Note

PORTB PDR = 0x0008C00B, PODR = 0x0008C02B, PIDR = 0x0008C04B

144-pin: PB0-PB7 available

Definition at line 743 of file rx72n\_port\_regs.h.

```
00744 {
00745 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_b);
00746 }
```

References [k\\_port\\_offset\\_b](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

#### 5.7.4.24 portb\_odr()

```
volatile uint16_t * portb_odr (
 void) [inline], [static]
```

Get pointer to PORTB ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORTB.ODR = 0x0008C096

Definition at line 936 of file [rx72n\\_port\\_regs.h](#).

```
00937 {
00938 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_b * 2));
00939 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_b](#).

#### 5.7.4.25 portc()

```
volatile rx_port_regs_t * portc (
 void) [inline], [static]
```

Get pointer to PORTC registers.

Returns

Volatile pointer to PORTC register structure

Note

PORTC PDR = 0x0008C00C, PODR = 0x0008C02C, PIDR = 0x0008C04C  
144-pin: PC0-PC7 available

Definition at line 754 of file [rx72n\\_port\\_regs.h](#).

```
00755 {
00756 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_c);
00757 }
```

References [k\\_port\\_offset\\_c](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

#### 5.7.4.26 portc odr()

```
volatile uint16_t * portc_odr (
 void) [inline], [static]
```

Get pointer to PORTC ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORTC.ODR = 0x0008C098

Definition at line 946 of file [rx72n\\_port\\_regs.h](#).

```
00947 {
00948 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_c * 2));
00949 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_c](#).

### 5.7.4.27 portd()

```
volatile rx_port_regs_t * portd (
 void) [inline], [static]
```

Get pointer to PORTD registers.

Returns

Volatile pointer to PORTD register structure

Note

PORTD PDR = 0x0008C00D, PODR = 0x0008C02D, PIDR = 0x0008C04D

144-pin: PD0-PD7 available

Definition at line 765 of file [rx72n\\_port\\_regs.h](#).

```
00766 {
00767 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_d);
00768 }
```

References [k\\_port\\_offset\\_d](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

## 5.7.4.28 portd odr()

```
volatile uint16_t * portd_odr (
 void) [inline], [static]
```

Get pointer to PORTD ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORTD.ODR = 0x0008C09A

Definition at line 956 of file [rx72n\\_port\\_regs.h](#).

```
00957 {
00958 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_d * 2));
00959 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_d](#).

## 5.7.4.29 porte()

```
volatile rx_port_regs_t * porte (
 void) [inline], [static]
```

Get pointer to PORTE registers.

Returns

Volatile pointer to PORTE register structure

Note

PORTE PDR = 0x0008C00E, PODR = 0x0008C02E, PIDR = 0x0008C04E  
144-pin: PE0-PE7 available

Definition at line 776 of file [rx72n\\_port\\_regs.h](#).

```
00777 {
00778 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_e);
00779 }
```

References [k\\_port\\_offset\\_e](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

#### 5.7.4.30 porteodr()

```
volatile uint16_t * porteodr (
 void) [inline], [static]
```

Get pointer to PORTE ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

`PORTE.ODR = 0x0008C09C`

Definition at line 966 of file `rx72n_port_regs.h`.

```
00967 {
00968 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_e * 2));
00969 }
```

References `k_port_odr0_base`, and `k_port_offset_e`.

## 5.7.4.31 portf()

```
volatile rx_port_regs_t * portf (
 void) [inline], [static]
```

Get pointer to PORTF registers.

Returns

Volatile pointer to PORTF register structure

Note

PORTF PDR = 0x0008C00F, PODR = 0x0008C02F, PIDR = 0x0008C04F  
 144-pin: PF5 available (1 pin)

Definition at line 788 of file rx72n\_port\_regs.h.

```
00789 {
00790 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_f);
00791 }
```

References [k\\_port\\_offset\\_f](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

### 5.7.4.32 portfodr()

```
volatile uint16_t * portfodr (
 void) [inline], [static]
```

Get pointer to PORTF ODR register.

Returns

Volatile pointer to 16-bit ODR register

Note

PORTF.ODR = 0x0008C09E (offset 0x0F \* 2)

Definition at line 976 of file [rx72n\\_port\\_regs.h](#).

```
00977 {
00978 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_f * 2));
00979 }
```

References [k\\_port\\_odr0\\_base](#), and [k\\_port\\_offset\\_f](#).

### 5.7.4.33 portj()

```
volatile rx_port_regs_t * portj (
 void) [inline], [static]
```

Get pointer to PORTJ registers.

Returns

Volatile pointer to PORTJ register structure

Note

PORTJ PDR = 0x0008C012, PODR = 0x0008C032, PIDR = 0x0008C052  
144-pin: PJ3, PJ5 available (2 pins)

Definition at line 800 of file [rx72n\\_port\\_regs.h](#).

```
00801 {
00802 return (volatile rx_port_regs_t*)(k_port_pdr_base + k_port_offset_j);
00803 }
```

References [k\\_port\\_offset\\_j](#), and [k\\_port\\_pdr\\_base](#).

Referenced by [rx\\_port\\_get\\_base\(\)](#).

Here is the caller graph for this function:

5.7.4.34 `portj odr()`

```
volatile uint16_t * portj_odr (
 void) [inline], [static]
```

Get pointer to PORTJ ODR register.

## Returns

Volatile pointer to 16-bit ODR register

Note

PORTJ.ODR = 0x0008C0A4 (offset 0x12 \* 2)

Definition at line 986 of file rx72n\_port\_regs.h.

```
00987 {
00988 return (volatile uint16_t*)(k_port_odr0_base + (k_port_offset_j * 2));
00989 }
```

References `k_port_odr0_base`, and `k_port_offset_j`.

## 5.8 RIIC Register Definitions

I2C Bus Interface (RIIC) hardware register interface.

Collaboration diagram for RIIC Register Definitions:

## Topics

- [RIIC Static Assertions](#)  
Compile-time verification of RIIC register layout.

## Data Structures

- struct [rx\\_riic\\_regs\\_t](#)  
RIIC Channel Register Map (20 bytes per channel).

## Enumerations

- enum [rx\\_riic\\_addresses\\_t](#) : [uintptr\\_t](#) { [k\\_riic0\\_base\\_addr](#) = 0x00088300 , [k\\_riic1\\_base\\_addr](#) = 0x00088320 , [k\\_riic2\\_base\\_addr](#) = 0x00088340 }
- RIIC channel base addresses (verified against RX72N Hardware Manual Ch42).
- enum [riic\\_iccr1\\_bits\\_t](#) : [uint8\\_t](#) {  
[k\\_riic\\_iccr1\\_ice](#) = (1 << 7) , [k\\_riic\\_iccr1\\_iicrst](#) = (1 << 6) , [k\\_riic\\_iccr1\\_clo](#) = (1 << 5) ,

[k\\_riic\\_icsr2\\_tmof](#) = (1 << 0) }
- ICSR2 (I2C Status Register 2) bit definitions.

## Functions

- static volatile [rx\\_riic\\_regs\\_t](#) \* [riic0](#) (void)  
Get pointer to RIIC0 registers.
- static volatile [rx\\_riic\\_regs\\_t](#) \* [riic1](#) (void)  
Get pointer to RIIC1 registers.
- static volatile [rx\\_riic\\_regs\\_t](#) \* [riic2](#) (void)  
Get pointer to RIIC2 registers.

## 5.8.1 Detailed Description

I2C Bus Interface (RIIC) hardware register interface.

## 5.8.2 Data Structure Documentation

### 5.8.2.1 struct rx\_riic\_regs\_t

RIIC Channel Register Map (20 bytes per channel).

I2C Bus Interface (RIIC) registers for I2C controller/peripheral communication. All registers are 8-bit and byte-accessible.

Register Layout (20 bytes)

| * Offset | Size | Register | Description                      |
|----------|------|----------|----------------------------------|
| * 0x00   | 1    | ICCR1    | Control 1 (enable, reset)        |
| * 0x01   | 1    | ICCR2    | Control 2 (start, stop, restart) |
| * 0x02   | 1    | ICMR1    | Mode 1 (clock divider)           |
| * 0x03   | 1    | ICMR2    | Mode 2 (timeout, SDA delay)      |
| * 0x04   | 1    | ICMR3    | Mode 3 (ACK/NACK control)        |
| * 0x05   | 1    | ICFER    | Function Enable                  |
| * 0x06   | 1    | ICSER    | Status Enable                    |
| * 0x07   | 1    | ICIER    | Interrupt Enable                 |
| * 0x08   | 1    | ICSR1    | Status 1 (ACK status)            |
| * 0x09   | 1    | ICSR2    | Status 2 (TX/RX flags)           |
| * 0x0A   | 1    | SARL0    | Peripheral Address 0 Low         |
| * 0x0B   | 1    | SARU0    | Peripheral Address 0 Upper       |
| * 0x0C   | 1    | SARL1    | Peripheral Address 1 Low         |
| * 0x0D   | 1    | SARU1    | Peripheral Address 1 Upper       |
| * 0x0E   | 1    | SARL2    | Peripheral Address 2 Low         |
| * 0x0F   | 1    | SARU2    | Peripheral Address 2 Upper       |
| * 0x10   | 1    | ICBRL    | Bit Rate Low period              |
| * 0x11   | 1    | ICBRH    | Bit Rate High period             |
| * 0x12   | 1    | ICDRT    | Transmit Data                    |
| * 0x13   | 1    | ICDRR    | Receive Data                     |
| *        |      |          |                                  |

Initialization Sequence

1. Set IICRST bit in ICCR1 (internal reset)
2. Configure ICMR1/2/3 (clock, timeouts)
3. Configure ICBRL/ICBRH (bit rate)
4. Configure ICSER (status detection)
5. Configure ICIER (interrupts)
6. Clear IICRST and set ICE in ICCR1 (enable)

Invariant

```
sizeof(rx_riic_regs_t) == 20
```

### 5.8.3 Enumeration Type Documentation

#### 5.8.3.1 riic'icr1'bits't

enum `riic_icr1_bits_t` : `uint8_t`

ICCR1 (I2C Control Register 1) bit definitions.

Controls RIIC module enable/disable, internal reset, bus recovery clock, and provides pin output control and input monitoring.

Register Layout

```

* Bit | Name | Description
* ----+-----+-----
* 7 | ICE | RIIC Enable (1=enabled, 0=disabled)
* 6 | IICRST | Internal Reset (1=reset state)
* 5 | CLO | Additional SCL Output (bus recovery clock)
* 4 | SOWP | SCLO and SDAO Write Protect
* 3 | SCLO | SCL Output Control/Monitor
* 2 | SDAO | SDA Output Control/Monitor
* 1 | SCLI | SCL Line Input Monitor (read-only)
* 0 | SDAI | SDA Line Input Monitor (read-only)
*

```

## Enumerator

|                     |                                             |
|---------------------|---------------------------------------------|
| k_riic_iccr1_ice    | Bit 7: I2C Bus Interface Enable             |
| k_riic_iccr1_iicrst | Bit 6: Internal Reset (hold in reset)       |
| k_riic_iccr1_clo    | Bit 5: Additional SCL Output (bus recovery) |
| k_riic_iccr1_sowp   | Bit 4: SCLO and SDAO Write Protect          |
| k_riic_iccr1_sclo   | Bit 3: SCL Output Control/Monitor           |
| k_riic_iccr1_sdao   | Bit 2: SDA Output Control/Monitor           |
| k_riic_iccr1_scli   | Bit 1: SCL Line Input Monitor (read-only)   |
| k_riic_iccr1_sdai   | Bit 0: SDA Line Input Monitor (read-only)   |

Definition at line 495 of file `rx72n_riic_regs.h`.

```

00495 : uint8_t {
00496 k_riic_iccr1_ice = (1 << 7), /**< Bit 7: I2C Bus Interface Enable */
00497 k_riic_iccr1_iicrst = (1 << 6), /**< Bit 6: Internal Reset (hold in reset) */
00498 k_riic_iccr1_clo = (1 << 5), /**< Bit 5: Additional SCL Output (bus recovery) */
00499 k_riic_iccr1_sowp = (1 << 4), /**< Bit 4: SCLO and SDAO Write Protect */
00500 k_riic_iccr1_sclo = (1 << 3), /**< Bit 3: SCL Output Control/Monitor */
00501 k_riic_iccr1_sdao = (1 << 2), /**< Bit 2: SDA Output Control/Monitor */
00502 k_riic_iccr1_scli = (1 << 1), /**< Bit 1: SCL Line Input Monitor (read-only) */
00503 k_riic_iccr1_sdai = (1 << 0), /**< Bit 0: SDA Line Input Monitor (read-only) */
00504 } riic_iccr1_bits_t;

```

## 5.8.3.2 riic'iccr2'bits't

```
enum riic_iccr2_bits_t : uint8_t
```

ICCR2 (I2C Control Register 2) bit definitions.

Controls bus conditions (start, stop, restart) and provides bus status.

## Register Layout

```

* Bit | Name | R/W | Description
* ----+-----+-----+-----
* 7 | BBSY | R | Bus Busy (1=bus busy, 0=bus free)
* 6 | MST | R | Controller Mode (1=controller, 0=peripheral)
* 5 | TRS | R | Transmit Mode (1=transmit, 0=receive)
* 4 | - | - | Reserved
* 3 | SP | W | Stop Condition Request (write 1 to issue)
* 2 | RS | W | Restart Condition Request
* 1 | ST | W | Start Condition Request
* 0 | - | - | Reserved
*

```

## Note

ST, RS, SP bits are write-only and always read as 0.

## Enumerator

|                   |                                                        |

00535 k_riic_iccr2_st = (1 « 1), /**< Bit 1: Start Condition Request */
00536 } riic_iccr2_bits_t;

```

### 5.8.3.3 riic\_icsr1\_bits\_t

enum [riic\\_icsr1\\_bits\\_t](#) : uint8\_t

ICSR1 (I2C Status Register 1) bit definitions.

Contains peripheral address detection flags, general call detection, device-ID detection, and host address detection (peripheral mode).

Register Layout

```

* Bit | Name | Description
* ----+-----+-----
* 7 | HOA | Host Address Detection Flag
* 6 | - | Reserved
* 5 | DID | Device-ID Address Detection Flag
* 4 | - | Reserved
* 3 | GCA | General Call Address Detection Flag
* 2 | AAS2 | Peripheral Address 2 Detection Flag
* 1 | AAS1 | Peripheral Address 1 Detection Flag
* 0 | AAS0 | Peripheral Address 0 Detection Flag
*

```

Usage

```

if (riic0()->icsr1 & k_riic_icsr1_aas0) {
 // Peripheral address 0 detected - we are being addressed
}

```

Enumerator

|                   |                                            |
|-------------------|--------------------------------------------|
| k_riic_icsr1_hoa  | Bit 7: Host Address Detection Flag         |
| k_riic_icsr1_did  | Bit 5: Device-ID Address Detection Flag    |
| k_riic_icsr1_gca  | Bit 3: General Call Address Detection Flag |
| k_riic_icsr1_aas2 | Bit 2: Peripheral Address 2 Detection Flag |
| k_riic_icsr1_aas1 | Bit 1: Peripheral Address 1 Detection Flag |
| k_riic_icsr1_aas0 | Bit 0: Peripheral Address 0 Detection Flag |

Definition at line 567 of file [rx72n\\_riic\\_regs.h](#).

```

00567 : uint8_t {
00568 k_riic_icsr1_hoa = (1 « 7), /**< Bit 7: Host Address Detection Flag */
00569 k_riic_icsr1_did = (1 « 5), /**< Bit 5: Device-ID Address Detection Flag */
00570 k_riic_icsr1_gca = (1 « 3), /**< Bit 3: General Call Address Detection Flag */

00574 } riic_icsr1_bits_t;

```

## 5.8.3.4 riic\_icsr2\_bits\_t

```
enum riic_icsr2_bits_t : uint8_t
```

ICSR2 (I2C Status Register 2) bit definitions.

Contains transmit/receive status flags and condition detection.

Register Layout

```
* Bit | Name | Description
* ----+-----+-----
* 7 | TDRE | Transmit Data Empty (1=can write ICDRT)
* 6 | TEND | Transmit End (1=all data transmitted)
* 5 | RDRF | Receive Data Full (1=data in ICDRR)
* 4 | NACKF | NACK Detection Flag
* 3 | STOP | Stop Condition Detected
* 2 | START | Start Condition Detected
* 1 | AL | Arbitration-Lost Flag
* 0 | TMOF | Timeout Detection Flag
*
```

Typical Polling Sequence

```
// Wait for transmit ready
while (!(riic0()->icsr2 & k_riic_icsr2_tdre)) {}

// Wait for receive complete
while (!(riic0()->icsr2 & k_riic_icsr2_rdrf)) {}
```

Enumerator

```

### 5.8.3.5 rx\_riic\_addresses\_t

```
enum rx_riic_addresses_t : uintptr_t
```

RIIC channel base addresses (verified against RX72N Hardware Manual Ch42).

The RX72N has 3 independent RIIC channels. Each channel has a 32-byte register block (though only 20 bytes are used).

#### Memory Layout

```
* Address | Channel | Pins
* -----+-----+-----
* 0x00088300 | RIIC0 | P16/SCL0, P17/SDA0
* 0x00088320 | RIIC1 | P21/SCL1, P20/SDA1
* 0x00088340 | RIIC2 | P66/SCL2, P67/SDA2
*
```

#### Note

Channel spacing is 0x20 (32 bytes) between adjacent channels.

#### Enumerator

|                   |                             |
|-------------------|-----------------------------|
| k_riic0_base_addr | RIIC0 register base address |
| k_riic1_base_addr | RIIC1 register base address |
| k_riic2_base_addr | RIIC2 register base address |

00214 k_riic1_base_addr = 0x00088320, /**< RIIC1 register base address */
00215 k_riic2_base_addr = 0x00088340, /**< RIIC2 register base address */
00216 } rx_riic_addresses_t;
```

## 5.8.4 Function Documentation

### 5.8.4.1 riic0()

```
volatile rx_riic_regs_t * riic0 (
 void) [inline], [static]
```

Get pointer to RIIC0 registers.

Returns a volatile pointer to RIIC channel 0 registers at address 0x00088300. RIIC0 pins are P16 (SCL0) and P17 (SDA0).

Returns

Volatile pointer to RIIC0 register structure

## Example

```
// Enable RIIC0
riic0()->iccr1 = k_riic_iccr1_ice;

// Start condition
riic0()->iccr2 = k_riic_iccr2_st;
```

Definition at line 440 of file `rx72n_riic_regs.h`.

```
00441 {
00442 return (volatile rx_riic_regs_t*)k_riic0_base_addr;
00443 }
```

References `k_riic0_base_addr`.

Referenced by `internal_get_riic_base()`.

Here is the caller graph for this function:

5.8.4.2 `riic1()`

```
volatile rx_riic_regs_t * riic1 (
 void) [inline], [static]
```

Get pointer to RIIC1 registers.

Returns a volatile pointer to RIIC channel 1 registers at address 0x00088320. RIIC1 pins are P21 (SCL1) and P20 (SDA1).

## Returns

Volatile pointer to RIIC1 register structure

Definition at line 454 of file [rx72n\\_riic\\_regs.h](#).

```
00455 {
00456 return (volatile rx_riic_regs_t*)k_riic1_base_addr;
00457 }
```

References [k\\_riic1\\_base\\_addr](#).

Referenced by [internal\\_get\\_riic\\_base\(\)](#).

Here is the caller graph for this function:

### 5.8.4.3 riic2()

```
volatile rx_riic_regs_t * riic2 (
 void) [inline], [static]
```

Get pointer to RIIC2 registers.

Returns a volatile pointer to RIIC channel 2 registers at address 0x00088340. RIIC2 pins are P66 (SCL2) and P67 (SDA2).

## Returns

Volatile pointer to RIIC2 register structure

Definition at line 468 of file [rx72n\\_riic\\_regs.h](#).

```
00469 {
00470 return (volatile rx_riic_regs_t*)k_riic2_base_addr;
00471 }
```

References [k\\_riic2\\_base\\_addr](#).

Referenced by [internal\\_get\\_riic\\_base\(\)](#).

### 5.8.5 RIIC Static Assertions

Compile-time verification of RIIC register layout.

Collaboration diagram for RIIC Static Assertions:

Compile-time verification of RIIC register layout.

These static assertions are verified at compile time to ensure the C structure definitions match the actual hardware register layout. A failed assertion indicates a bug in the register definitions that must be fixed before the code can compile.

## 5.9 SCI Register Definitions

### Data Structures

- struct `rx_sci_regs_t`  
SCI register map covering UART and SPI mode registers (14 bytes).

## Enumerations

- enum `rx_sci_addresses_t` : `uintptr_t` {  
`k_sci0_base_addr` = 0x0008A000 , `k_sci1_base_addr` = 0x0008A020 , `k_sci2_base_addr` = 0x0008A040 , `k_sci3_base_addr` = 0x0008A060 ,  
`k_sci4_base_addr` = 0x0008A080 , `k_sci5_base_addr` = 0x0008A0A0 , `k_sci6_base_addr` = 0x0008A0C0 , `k_sci7_base_addr` = 0x000D00E0 ,  
`k_sci8_base_addr` = 0x000D0000 , `k_sci9_base_addr` = 0x000D0020 , `k_sci10_base_addr` = 0x000D0040 , `k_sci11_base_addr` = 0x000D0060 ,  
`k_sci12_base_addr` = 0x0008B300 }

SCI channel base addresses (verified against RX72N Hardware Manual).

- enum `rx_sci_ssr_flags_t` : `uint8_t` {  
`k_sci_ssr_tdre_flag` = 0x80U , `k_sci_ssr_rdrf_flag` = 0x40U , `k_sci_ssr_orer_flag` = 0x20U ,  
`k_sci_ssr_fer_flag` = 0x10U ,  
`k_sci_ssr_per_flag` = 0x08U , `k_sci_ssr_tend_flag` = 0x04U , `k_sci_ssr_error_mask` = 0x38U  
}

SCI Serial Status Register (SSR) flag masks.

- enum `sci_channel_limits_t` : `uint8_t` { `k_sci_channel_max` = 13 }

SCI channel count.

## Functions

- static volatile `rx_sci_regs_t * sci0` (void)  
Get pointer to SCI0 registers.
- static volatile `rx_sci_regs_t * sci1` (void)  
Get pointer to SCI1 registers.
- static volatile `rx_sci_regs_t * sci2` (void)  
Get pointer to SCI2 registers.
- static volatile `rx_sci_regs_t * sci3` (void)  
Get pointer to SCI3 registers.
- static volatile `rx_sci_regs_t * sci4` (void)  
Get pointer to SCI4 registers.
- static volatile `rx_sci_regs_t * sci5` (void)  
Get pointer to SCI5 registers.
- static volatile `rx_sci_regs_t * sci6` (void)  
Get pointer to SCI6 registers.
- static volatile `rx_sci_regs_t * sci7` (void)  
Get pointer to SCI7 registers.
- static volatile `rx_sci_regs_t * sci8` (void)  
Get pointer to SCI8 registers.
- static volatile `rx_sci_regs_t * sci9` (void)  
Get pointer to SCI9 registers (Debug UART).
- static volatile `rx_sci_regs_t * sci10` (void)  
Get pointer to SCI10 registers.
- static volatile `rx_sci_regs_t * sci11` (void)  
Get pointer to SCI11 registers.
- static volatile `rx_sci_regs_t * sci12` (void)  
Get pointer to SCI12 registers.
- static volatile `rx_sci_regs_t * sci_get_channel` (uint8\_t channel)  
Get SCI register base for a channel.

## 5.9.1 Detailed Description

## 5.9.2 Data Structure Documentation

### 5.9.2.1 struct rx\_sci\_regs\_t

SCI register map covering UART and SPI mode registers (14 bytes).

Memory-mapped register structure for the RX72N SCI peripheral. Covers registers from SMR (0x00) through SPMR (0x0D) to support both asynchronous UART and clock-synchronous SPI modes.

Register Memory Layout (14 bytes total)

| * Offset | Size | Register | Description                                     |
|----------|------|----------|-------------------------------------------------|
| * 0x00   | 1    | SMR      | Serial Mode (data format, clock source)         |
| * 0x01   | 1    | BRR      | Bit Rate (baud rate divisor)                    |
| * 0x02   | 1    | SCR      | Serial Control (TX/RX enable, interrupts)       |
| * 0x03   | 1    | TDR      | Transmit Data (write-only data buffer)          |
| * 0x04   | 1    | SSR      | Serial Status (flags, error conditions)         |
| * 0x05   | 1    | RDR      | Receive Data (read-only data buffer)            |
| * 0x06   | 1    | SCMR     | Smart Card Mode (SDIR for bit order)            |
| * 0x07   | 1    | SEMR     | Serial Extended Mode (noise filter, modulation) |
| * 0x08   | 1    | SNFR     | Noise Filter Setting                            |
| * 0x09   | 1    | SIMR1    | I2C Mode Register 1                             |
| * 0x0A   | 1    | SIMR2    | I2C Mode Register 2                             |
| * 0x0B   | 1    | SIMR3    | I2C Mode Register 3                             |
| * 0x0C   | 1    | SISR     | I2C Status Register                             |
| * 0x0D   | 1    | SPMR     | SPI Mode Register (CKPH, CKPOL)                 |

### UART Transmission Sequence

- \* 1. Wait for SSR.TDRE = 1 (transmit data register empty)
- \* 2. Write data byte to TDR
- \* 3. SSR.TDRE automatically clears to 0
- \* 4. Data shifts out serially via TXD pin
- \* 5. SSR.TEND = 1 when transmission complete
- \*

### UART Reception Sequence

- \* 1. Data arrives via RXD pin
- \* 2. SSR.RDRF = 1 when byte received
- \* 3. Read data byte from RDR
- \* 4. SSR.RDRF automatically clears to 0
- \* 5. Check SSR.ORER/FER/PER for errors
- \*

### Transmit Character Example

```
void uart_putc(volatile rx_sci_regs_t* uart, char c)
{
 // Wait for transmit buffer empty
 while ((uart->ssr & 0x80) == 0) {
 // SSR.TDRE bit 7
 }
 // Write character to transmit
 uart->tdr = (uint8_t)c;
}
```

## Receive Character Example

```
char uart_getc(volatile rx_sci_regs_t* uart)
{
 // Wait for receive data ready
 while ((uart->ssr & 0x40) == 0) {
 // SSR.RDRF bit 6
 }
 // Read received character
 return (char)uart->rdr;
}
```

## Invariant

Structure size must be exactly 14 bytes  
All registers are 8-bit (byte-accessible)

## Note

Offsets 0x00-0x07 are unchanged from the original 8-byte structure. Existing UART code works unmodified. Offsets 0x08-0x0D add I2C mode and SPI mode register access needed for clock-synchronous SPI.

### 5.9.3 Enumeration Type Documentation

#### 5.9.3.1 rx'sci'addresses't

```
enum rx_sci_addresses_t : uintptr_t
```

SCI channel base addresses (verified against RX72N Hardware Manual).

Base addresses for all 13 SCI channels. The RX72N organizes SCI channels into three modules in different memory regions:

## Memory Map Overview

| * Address Range         | Module | Channels | Notes                            |
|-------------------------|--------|----------|----------------------------------|
| * -----                 |        |          |                                  |
| * 0x0008A000-0x0008A0DF | SCIj   | SCI0-6   | Standard region, 0x20 spacing    |
| * 0x000D0000-0x000D00FF | SCIi   | SCI7-11  | Extended region, varying spacing |
| * 0x0008B300-0x0008B31F | SCIh   | SCI12    | Standard region, separate        |
| *                       |        |          |                                  |

## Channel Spacing

- SCIj (SCI0-6): 0x20 bytes between channels
- SCIi (SCI7-11): Non-uniform spacing (see individual addresses)
- SCIh (SCI12): Standalone at 0x0008B300

## STAR Robot Usage

SCI9 is designated as the debug UART, connected to the CY7C65213 USB-UART bridge IC for host PC communication at 115200 baud.

```

### 5.9.3.2 rx\_sci\_ssr\_flags\_t

```
enum rx_sci_ssr_flags_t : uint8_t
```

SCI Serial Status Register (SSR) flag masks.

Bit masks for the SSR register per RX72N HUM 34.2.7. Error flags (ORER, FER, PER) are sticky and must be cleared by read-modify-write with a 0 written to the bit position (writing 1 has no effect).

Note

Bit positions match both the SCIIa/b/c/d/e/f (standard) and SCIIg/h/i (extended) SSR layouts – the same mask works for all SCI channels on the RX72N.

Enumerator

|                      |                                                 |
|----------------------|-------------------------------------------------|
| k_sci_ssr_tdre_flag  | Transmit data register empty (HUM 34.2.7 bit 7) |
| k_sci_ssr_rdrf_flag  | Receive data register full (bit 6)              |
| k_sci_ssr_orer_flag  | Overrun error (bit 5)                           |

```

### 5.9.3.3 sci\_channel\_limits\_t

enum [sci\\_channel\\_limits\\_t](#) : uint8\_t

SCI channel count.

Enumerator

|                   |                           |
|-------------------|---------------------------|
| k_sci_channel_max | Total SCI channels (0-12) |
|-------------------|---------------------------|

Definition at line 614 of file [rx72n\\_sci\\_regs.h](#).

```
00614 : uint8_t {
00615 k_sci_channel_max = 13, /**< Total SCI channels (0-12) */
00616 } sci_channel_limits_t;
```

## 5.9.4 Function Documentation

### 5.9.4.1 sci0()

volatile [rx\\_sci\\_regs\\_t](#) \* sci0 (  
void ) [inline], [static]

Get pointer to SCI0 registers.

Returns

Volatile pointer to SCI0 register structure

Definition at line 493 of file [rx72n\\_sci\\_regs.h](#).

```
00494 {
00495 return (volatile rx_sci_regs_t*)k_sci0_base_addr;
00496 }
```

References [k\\_sci0\\_base\\_addr](#).

Referenced by [sci\\_get\\_channel\(\)](#).

Here is the caller graph for this function:

## 5.9.4.2 sci1()

```
volatile rx_sci_regs_t * sci1 (
 void) [inline], [static]
```

Get pointer to SCI1 registers.

Returns

Volatile pointer to SCI1 register structure

Definition at line 502 of file rx72n\_sci\_regs.h.

```
00503 {
00504 return (volatile rx_sci_regs_t*)k_sci1_base_addr;
00505 }
```

References [k\\_sci1\\_base\\_addr](#).

Referenced by [sci\\_get\\_channel\(\)](#).

Here is the caller graph for this function:

## 5.9.4.3 sci10()

```
volatile rx_sci_regs_t * sci10 (
 void) [inline], [static]
```

Get pointer to SCI10 registers.

Returns

Volatile pointer to SCI10 register structure

Definition at line 583 of file rx72n\_sci\_regs.h.

```
00584 {
00585 return (volatile rx_sci_regs_t*)k_sci10_base_addr;
00586 }
```

References [k\\_sci10\\_base\\_addr](#).

Referenced by [sci\\_get\\_channel\(\)](#).

Here is the caller graph for this function:

#### 5.9.4.4 sci11()

```
volatile rx_sci_regs_t * sci11 (
 void) [inline], [static]
```

Get pointer to SCI11 registers.

Returns

Volatile pointer to SCI11 register structure

Definition at line 592 of file rx72n\_sci\_regs.h.

```
00593 {
00594 return (volatile rx_sci_regs_t*)k_sci11_base_addr;
00595 }
```

References [k\\_sci11\\_base\\_addr](#).

Referenced by [sci\\_get\\_channel\(\)](#).

Here is the caller graph for this function:

## 5.9.4.5 sci12()

```
volatile rx_sci_regs_t * sci12 (
 void) [inline], [static]
```

Get pointer to SCI12 registers.

Returns

Volatile pointer to SCI12 register structure

Definition at line 601 of file rx72n\_sci\_regs.h.

```
00602 {
00603 return (volatile rx_sci_regs_t*)k_sci12_base_addr;
00604 }
```

References [k\\_sci12\\_base\\_addr](#).

Referenced by [sci\\_get\\_channel\(\)](#).

Here is the caller graph for this function:

## 5.9.4.6 sci2()

```
volatile rx_sci_regs_t * sci2 (
 void) [inline], [static]
```

Get pointer to SCI2 registers.

Returns

Volatile pointer to SCI2 register structure

Definition at line 511 of file rx72n\_sci\_regs.h.

```
00512 {
00513 return (volatile rx_sci_regs_t*)k_sci2_base_addr;
00514 }
```

References [k\\_sci2\\_base\\_addr](#).

Referenced by [sci\\_get\\_channel\(\)](#).

Here is the caller graph for this function:

#### 5.9.4.7 sci3()

```
volatile rx_sci_regs_t * sci3 (
 void) [inline], [static]
```

Get pointer to SCI3 registers.

Returns

Volatile pointer to SCI3 register structure

Definition at line 520 of file rx72n\_sci\_regs.h.

```
00521 {
00522 return (volatile rx_sci_regs_t*)k_sci3_base_addr;
00523 }
```

References [k\\_sci3\\_base\\_addr](#).

Referenced by [sci\\_get\\_channel\(\)](#).

Here is the caller graph for this function:

## 5.9.4.8 sci4()

```
volatile rx_sci_regs_t * sci4 (
 void) [inline], [static]
```

Get pointer to SCI4 registers.

Returns

Volatile pointer to SCI4 register structure

Definition at line 529 of file rx72n\_sci\_regs.h.

```
00530 {
00531 return (volatile rx_sci_regs_t*)k_sci4_base_addr;
00532 }
```

References [k\\_sci4\\_base\\_addr](#).

Referenced by [sci\\_get\\_channel\(\)](#).

Here is the caller graph for this function:

## 5.9.4.9 sci5()

```
volatile rx_sci_regs_t * sci5 (
 void) [inline], [static]
```

Get pointer to SCI5 registers.

Returns

Volatile pointer to SCI5 register structure

Definition at line 538 of file rx72n\_sci\_regs.h.

```
00539 {
00540 return (volatile rx_sci_regs_t*)k_sci5_base_addr;
00541 }
```

References [k\\_sci5\\_base\\_addr](#).

Referenced by [sci\\_get\\_channel\(\)](#).

Here is the caller graph for this function:

#### 5.9.4.10 sci6()

```
volatile rx_sci_regs_t * sci6 (
 void) [inline], [static]
```

Get pointer to SCI6 registers.

Returns

Volatile pointer to SCI6 register structure

Definition at line 547 of file rx72n\_sci\_regs.h.

```
00548 {
00549 return (volatile rx_sci_regs_t*)k_sci6_base_addr;
00550 }
```

References [k\\_sci6\\_base\\_addr](#).

Referenced by [sci\\_get\\_channel\(\)](#).

Here is the caller graph for this function:

## 5.9.4.11 sci7()

```
volatile rx_sci_regs_t * sci7 (
 void) [inline], [static]
```

Get pointer to SCI7 registers.

Returns

Volatile pointer to SCI7 register structure

Definition at line 556 of file rx72n\_sci\_regs.h.

```
00557 {
00558 return (volatile rx_sci_regs_t*)k_sci7_base_addr;
00559 }
```

References [k\\_sci7\\_base\\_addr](#).

Referenced by [sci\\_get\\_channel\(\)](#).

Here is the caller graph for this function:

## 5.9.4.12 sci8()

```
volatile rx_sci_regs_t * sci8 (
 void) [inline], [static]
```

Get pointer to SCI8 registers.

Returns

Volatile pointer to SCI8 register structure

Definition at line 565 of file rx72n\_sci\_regs.h.

```
00566 {
00567 return (volatile rx_sci_regs_t*)k_sci8_base_addr;
00568 }
```

Here is the caller graph for this function:

## 5.9.4.14 sci\_get\_channel()

```
volatile rx_sci_regs_t * sci_get_channel (
 uint8_t channel) [inline], [static]
```

Get SCI register base for a channel.

Parameters

|    |         |                           |
|----|---------|---------------------------|
| in | channel | SCI channel number (0-12) |
|----|---------|---------------------------|

Returns

Pointer to SCI registers, or nullptr if invalid channel

Definition at line 626 of file rx72n\_sci\_regs.h.

```
00627 {
00628 switch (channel) {
00629 case 0:
00630 return sci0();
00631 case 1:
00632 return sci1();
00633 case 2:
00634 return sci2();

## 5.10 Task-Level Watchdog Monitoring

Software layer for per-task heartbeat tracking.

### Data Structures

- struct `task_monitor_t`  
Task monitoring state for a single registered task.
- struct `task_monitor_state_t`  
Complete task monitoring module state.

### Enumerations

- enum `task_registration_state_t` : `uint8_t` { `k_task_not_registered` = 0 , `k_task_registered` = 1 }
  - enum `task_search_constants_t` : `int32_t` { `k_task_not_found` = -1 , `k_task_idx_min` = 0 }
- Task registration state tracking.
- Constants for task search operations.

### Functions

- static `int32_t` `internal_find_task` (`const char *task_name`)  
Find task index by name in the registered tasks array.
- `rx_err_t` `rx_hal_iwdt_register_task` (`const char *task_name`, `uint32_t timeout_ms`)  
Register a task for watchdog monitoring.
- void `rx_hal_iwdt_task_heartbeat` (`const char *task_name`)  
Record a task heartbeat to indicate liveness.
- `rx_err_t` `rx_hal_iwdt_check_tasks` (void)  
Check all monitored tasks for timeout violations.
- `const char *` `rx_hal_iwdt_get_failed_task` (void)  
Get name of last failed task for post-mortem analysis.

### Variables

- static `task_monitor_state_t` `s_task_monitor` = {}  
Module state for task monitoring (static allocation).

### 5.10.1 Detailed Description

Software layer for per-task heartbeat tracking.

Provides fine-grained monitoring of individual RTOS tasks beyond hardware watchdog. Tasks register with unique names and timeout periods, then must send periodic heartbeats. A monitoring task checks for timeouts and identifies which specific task has hung.

#### Architecture

### 5.10.2 Data Structure Documentation

#### 5.10.2.1 struct task\_monitor\_t

Task monitoring state for a single registered task.

Stores all information needed to track one task's heartbeat status. Each registered task gets one slot in the `s_task_monitor.tasks[]` array.

Memory Layout (~32 bytes per task)

```

* Offset 0: task_name[16] [16 bytes] - Null-terminated name
* Offset 16: timeout_ms [4 bytes] - Heartbeat timeout
* Offset 20: last_heartbeat_ms [4 bytes] - Last heartbeat timestamp
* Offset 24: registered [1 byte] - Registration state
* Offset 25: padding [7 bytes] - Alignment padding
* Total: ~32 bytes (depends on alignment)
*

```

## Timeout Check Algorithm

```

* elapsed = current_time - last_heartbeat_ms
* if (elapsed > timeout_ms) -> Task has timed out
*

```

## Invariant

```

task_name is null-terminated
timeout_ms >= k_iwdt_timeout_min_ms
If registered == k_task_registered, task_name[0] != '\0'

```

Since

Version 1.0.0

Definition at line 1169 of file [rx\\_iwdt.c](#).

Collaboration diagram for task\_monitor\_t:

## Data Fields

|                                           |                                                     |                                                          |
|-------------------------------------------|-----------------------------------------------------|----------------------------------------------------------|
| uint32_t                                  | last_heartbeat_ms                                   | Timestamp (tx_time_get) of last heartbeat                |
| <a href="#">task_registration_state_t</a> | registered                                          | Whether this slot is in use                              |
| char                                      | task_name↔<br><a href="#">[k_task_name_max_len]</a> | Task identifier (null-terminated, truncated to 15 chars) |
| uint32_t                                  | timeout_ms                                          | Maximum time between heartbeats in milliseconds          |

## 5.10.2.2 struct task\_monitor\_state\_t

Complete task monitoring module state.

Contains all state for the task monitoring subsystem. Statically allocated to avoid dynamic memory (NASA Power of 10 Rule 3). One instance exists as `s_task_monitor`.

Memory Layout (~520 bytes total)

```
* Offset 0: tasks[8] [~256 bytes] - Task array (8 x 32 bytes)
* Offset 256: task_count [1 byte] - Number of registered tasks
* Offset 257: failed_task[16] [16 bytes] - Failed task name buffer
* Offset 273: padding [7 bytes] - Alignment
* Total: ~280 bytes (actual layout depends on alignment)
*
```

Invariant

`task_count <= k_iwdt_max_tasks`

`failed_task` is null-terminated (or all zeros if no failure)

Since

Version 1.0.0

Definition at line 1200 of file `rx_iwdt.c`.

Collaboration diagram for `task_monitor_state_t`:

Data Fields

|                             |                                                                 |                                  |
|-----------------------------|-----------------------------------------------------------------|----------------------------------|
| <code>char</code>           | <code>failed_task↔</code><br><code>[k_task_name_max_len]</code> | Name of most recent failed task  |
| <code>uint8_t</code>        | <code>task_count</code>                                         | Number of registered tasks (0-8) |
| <code>task_monitor_t</code> | <code>tasks[k_iwdt_max_tasks]</code>                            | Array of task monitoring slots   |

### 5.10.3 Enumeration Type Documentation

#### 5.10.3.1 task`registration`state`t

enum [task\\_registration\\_state\\_t](#) : uint8\_t

Task registration state tracking.

Indicates whether a [task\\_monitor\\_t](#) slot is in use. Allows sparse array usage and efficient task lookup.

Since

Version 1.0.0

Enumerator

|                       |                                          |
|-----------------------|------------------------------------------|
| k_task_not_registered | Slot available for new task registration |
| k_task_registered     | Slot in use by registered task           |

Definition at line [1119](#) of file [rx\\_iwtdt.c](#).

```
01119 : uint8_t {
01120 k_task_not_registered = 0, /**< Slot available for new task registration */
01121 k_task_registered = 1, /**< Slot in use by registered task */
01122 } task_registration_state_t;
```

#### 5.10.3.2 task`search`constants`t

enum [task\\_search\\_constants\\_t](#) : int32\_t

Constants for task search operations.

Defines sentinel values and bounds for task array operations. Using signed int32\_t allows -1 sentinel for "not found" result.

Since

Version 1.0.0

Enumerator

|                  |                                          |
|------------------|------------------------------------------|
| k_task_not_found | Return value when task name not in array |
| k_task_idx_min   | Minimum valid task index (array start)   |

Definition at line [1134](#) of file [rx\\_iwtdt.c](#).

```
01134 : int32_t {
01135 k_task_not_found = -1, /**< Return value when task name not in array */
01136 k_task_idx_min = 0, /**< Minimum valid task index (array start) */
01137 } task_search_constants_t;
```

## 5.10.4 Function Documentation

### 5.10.4.1 internal\_find\_task()

```
int32_t internal_find_task (
 const char * task_name) [static]
```

Find task index by name in the registered tasks array.

Performs linear search through `s_task_monitor.tasks[]` to find a task matching the given name. Uses `strncmp` for safe string comparison.

#### Algorithm

- \* 1. Validate task\_name is not nullptr
- \* 2. Validate task\_name is not empty string
- \* 3. Linear scan through registered tasks (0 to task\_count-1):
- \*   - Compare names using `strncmp(task_name, k_task_name_cmp_len)`
- \*   - If match found: return index
- \* 4. If no match: return `k_task_not_found (-1)`
- \*

#### Complexity

- Time:  $O(n \times m)$  where  $n = \text{task\_count}$ ,  $m = \text{k\_task\_name\_cmp\_len}$
- Space:  $O(1)$  - no additional memory

#### Precondition

```
task_name != nullptr
task_name[0] != '\0'
```

#### Postcondition

```
Return value < s_task_monitor.task_count (if found)
Return value == k_task_not_found (if not found or invalid input)
```

#### Note

Uses `k_task_name_cmp_len (15)` for comparison, not full buffer  
 Empty string returns `k_task_not_found` (invalid task name)

#### See also

[rx\\_hal\\_iwdt\\_task\\_heartbeat\(\)](#) Primary caller  
[rx\\_hal\\_iwdt\\_register\\_task\(\)](#) Uses for duplicate detection

Since

Version 1.0.0

Definition at line 1269 of file `rx_iwdt.c`.

```

01270 {
01271 if (task_name == nullptr) {
01272 return k_task_not_found;
01273 }
01274
01275 if (task_name[0] == '\0') {
01276 return k_task_not_found; /* Empty task name invalid */
01277 }
01278
01279 for (uint32_t i = (uint32_t)k_task_idx_min; i < s_task_monitor.task_count; i++) {
01280 if (strcmp(s_task_monitor.tasks[i].task_name, task_name, k_task_name_cmp_len) == 0) {
01281 return (int32_t)i;
01282 }
01283 }
01284
01285 return k_task_not_found;
01286 }

```

References `k_task_idx_min`, `k_task_name_cmp_len`, `k_task_not_found`, and `s_task_monitor`.

Referenced by `rx_hal_iwdt_register_task()`, and `rx_hal_iwdt_task_heartbeat()`.

Here is the caller graph for this function:

#### 5.10.4.2 `rx_hal_iwdt_check_tasks()`

```

rx_err_t rx_hal_iwdt_check_tasks (
 void) [nodiscard]

```

Check all monitored tasks for timeout violations.

Check for task deadlocks.

Iterates through all registered tasks and compares elapsed time since last heartbeat against each task's configured timeout. If any task has exceeded its timeout, logs the failure and records the task name.

#### Check Algorithm

- \* 1. Validate IWDT is initialized
- \* 2. Validate task\_count is within bounds (detect corruption)
- \* 3. Get current time from ThreadX
- \* 4. For each registered task:
  - \* a. Calculate elapsed = current\_time - last\_heartbeat\_ms
  - \* b. If elapsed > timeout\_ms:
    - \* - Log error with task name and timeout
    - \* - Record failed task name
    - \* - Set result = k\_rx\_err\_timeout
- \* 5. Return result (k\_rx\_ok if all pass, k\_rx\_err\_timeout if any fail)
- \*

## Typical Usage Pattern

```
* Monitoring Task Loop:
* +-----+
* | 1. rx_hal_iwdt_check_tasks() |
* | 2. If all tasks OK: rx_hal_iwdt_feed() |
* | 3. If timeout: DON'T feed (let WDT reset) |
* | 4. tx_thread_sleep(check_interval) |
* | 5. Repeat |
* +-----+
*
```

## Precondition

IWDT must be initialized via [rx\\_hal\\_iwdt\\_init\(\)](#)

Called periodically from monitoring task

## Postcondition

If timeout detected, failed task name recorded in `s_task_monitor.failed_task`

Error logged for each timed-out task

Continues checking all tasks even if one fails (logs all failures)

## Note

Does NOT automatically feed hardware watchdog

Checks all tasks even after finding failure (comprehensive logging)

Uses `tx_time_get()` which returns `uint32_t` tick count

## Warning

Do NOT feed watchdog if this function returns `k_rx_err_timeout`

## Example:

```
static void watchdog_monitor_task(ULONG input) {
 while (1) {
 rx_err_t result = rx_hal_iwdt_check_tasks();

 if (result == k_rx_ok) {
 // All tasks healthy - feed hardware watchdog
 rx_hal_iwdt_feed();
 } else if (result == k_rx_err_timeout) {
 // Task deadlock detected!
 // DON'T feed - let hardware watchdog reset system
 const char* failed = rx_hal_iwdt_get_failed_task();
 uart_debug_printf("DEADLOCK: %s\\r\\n", failed);
 }

 tx_thread_sleep(100); // Check every 100ms
 }
}
```

#### 5.10.4.3 `rx_hal_iwdt_get_failed_task()`

```

const char * rx_hal_iwdt_get_failed_task (
 void)

```

Get name of last failed task for post-mortem analysis.

Get the name of the last failed task (if any).

Returns the name of the task that most recently exceeded its heartbeat timeout. This information is recorded by `rx_hal_iwdt_check_tasks()` when it detects a timeout. Useful for diagnosing which task caused a watchdog reset.

## Use Cases

- \* 1. Post-reset diagnostics:
- \* - After watchdog reset, call `rx_hal_iwdt_get_failed_task()`
- \* - Log failed task name for debugging
- \* - Helps identify deadlock/hang location
- \* 2. Pre-reset logging:
- \* - When `rx_hal_iwdt_check_tasks()` returns `k_rx_err_timeout`
- \* - Get failed task name and log before reset occurs
- \*

## Precondition

IWDT must be initialized via `rx_hal_iwdt_init()`  
`rx_hal_iwdt_check_tasks()` has been called and detected a timeout

## Postcondition

Returns pointer to `s_task_monitor.failed_task` (do not modify)  
 Returned pointer valid until next timeout detection

## Note

Returns pointer to internal static buffer - do not free  
 Buffer contents may change on next `rx_hal_iwdt_check_tasks()` failure  
 Returns NULL if `failed_task[0] == '\0'` (no failure recorded)

## Warning

Do not modify returned buffer (const pointer)  
 Buffer may be overwritten by next timeout detection

## Example:

```
// After detecting timeout
rx_err_t result = rx_hal_iwdt_check_tasks();
if (result == k_rx_err_timeout) {
 const char* failed = rx_hal_iwdt_get_failed_task();
 if (failed != nullptr) {
 uart_debug_printf("FATAL: Task '%s' deadlocked\r\n", failed);
 }
 // Let watchdog reset the system...
}

// After system restart
if (rx_hal_iwdt_was_reset()) {
 const char* failed = rx_hal_iwdt_get_failed_task();
 // Note: May be NULL if buffer not preserved across reset
}
```

## See also

`rx_hal_iwdt_check_tasks()` Records failed task name

Since

Version 1.0.0

Definition at line 1648 of file `rx_iwdt.c`.

```
01649 {
01650 if (s_iwdt_initialized != k_iwdt_initialized) {
01651 return nullptr;
01652 }
01653
01654 if (s_task_monitor.failed_task[0] != '\0') {
01655 return s_task_monitor.failed_task;
01656 }
01657
01658 return nullptr;
01659 }
```

References `k_iwdt_initialized`, `s_iwdt_initialized`, and `s_task_monitor`.

#### 5.10.4.4 `rx_hal_iwdt_register_task()`

```
rx_err_t rx_hal_iwdt_register_task (
 const char * task_name,
 uint32_t timeout_ms) [nodiscard]
```

Register a task for watchdog monitoring.

Register a task for heartbeat monitoring.

Adds a task to the monitoring array with specified timeout period. The task must subsequently call `rx_hal_iwdt_task_heartbeat()` within each timeout period to indicate liveness. Failed tasks are detected by `rx_hal_iwdt_check_tasks()`.

#### Registration Process

- \* 1. Validate task\_name (not nullptr, not empty)
- \* 2. Validate timeout\_ms (within allowed range)
- \* 3. Check capacity (task\_count < k\_iwdt\_max\_tasks)
- \* 4. Check for duplicate registration (same name)
- \* 5. Copy task name to slot (truncate if > 15 chars)
- \* 6. Initialize timeout and heartbeat timestamp
- \* 7. Mark slot as registered
- \* 8. Increment task\_count
- \*

#### Precondition

IWDT module initialized (but not strictly required for registration)

task\_name points to valid null-terminated string

timeout\_ms appropriate for task's execution frequency

#### Postcondition

Task added to `s_task_monitor.tasks[]`

`s_task_monitor.task_count` incremented

Initial heartbeat timestamp set to current time

## Invariant

`s_task_monitor.task_count`  $\leq$  `k_iwdt_max_tasks` at all times

## Note

Task name truncated to 15 characters if longer

First heartbeat auto-recorded at registration time

## Warning

Not thread-safe - call during initialization only

## Example:

```
// Register motor control task (must heartbeat every 500ms)
rx_err_t err = rx_hal_iwdt_register_task("MotorCtrl", 500);
if (err != k_rx_ok) {
 // Handle registration failure
 return err;
}

// In motor task loop
while (1) {
 motor_control_update();
 rx_hal_iwdt_task_heartbeat("MotorCtrl");
 tx_thread_sleep(10); // 100Hz loop
}
```

01381 s_task_monitor.task_count++;
01382
01383 rx_log_info(s_tag, "Registered task for monitoring");
01384
01385 return k_rx_ok;
01386 }

```

References [internal\\_find\\_task\(\)](#), [k\\_iwdt\\_max\\_tasks](#), [k\\_iwdt\\_timeout\\_max\\_ms](#), [k\\_task\\_name\\_cmp\\_len](#), [k\\_task\\_not\\_found](#), [k\\_task\\_registered](#), [task\\_monitor\\_t::last\\_heartbeat\\_ms](#), [task\\_monitor\\_t::registered](#), [s\\_tag](#), [s\\_task\\_monitor](#), [task\\_monitor\\_t::task\\_name](#), and [task\\_monitor\\_t::timeout\\_ms](#).

Here is the call graph for this function:

#### 5.10.4.5 rx\_hal\_iwdt\_task\_heartbeat()

```

void rx_hal_iwdt_task_heartbeat (
 const char * task_name)

```

Record a task heartbeat to indicate liveness.

Record a task heartbeat.

Updates the `last_heartbeat_ms` timestamp for the specified task. Must be called by each monitored task at a rate faster than its configured timeout to avoid being flagged as failed by [rx\\_hal\\_iwdt\\_check\\_tasks\(\)](#).

#### Heartbeat Algorithm

- \* 1. Validate `task_name` (not nullptr)
- \* 2. Find task in registered array ([internal\\_find\\_task](#))
- \* 3. If found: Update `last_heartbeat_ms = tx_time_get()`
- \* 4. If not found: Log error (graceful degradation)
- \*

#### Timing Requirements

- \* - Must be called faster than task's `timeout_ms`
- \* - Typical pattern: Call at end of task's main loop iteration
- \* - Example: 500ms timeout -> call at least every 400ms
- \*

#### Precondition

`task_name` must be non-NULL

Task must be registered via [rx\\_hal\\_iwdt\\_register\\_task\(\)](#)

Called faster than task's configured timeout

## Postcondition

Task's last\_heartbeat\_ms updated to current time  
 No state change if task not found (logs error only)

## Note

Void return - errors logged but not returned  
 Unregistered task heartbeats are logged and ignored  
 Uses tx\_time\_get() for timestamp (ThreadX tick count)

## Warning

Missing heartbeats cause [rx\\_hal\\_iwdt\\_check\\_tasks\(\)](#) to detect timeout

## Example:

```
static void communication_task(ULONG input) {
 while (1) {
 // Process incoming messages
 process_messages();

 // Indicate task is alive
 rx_hal_iwdt_task_heartbeat("CommTask");

 // Wait for next iteration
 tx_thread_sleep(50); // 50ms loop
 }
}
```

Here is the call graph for this function:

### 5.10.5 Variable Documentation

#### 5.10.5.1 s'task'monitor

```
task_monitor_state_t s_task_monitor = {} [static]
```

Module state for task monitoring (static allocation).

Single instance of task monitoring state. Zero-initialized at startup, ensuring all tasks start unregistered and no failed task recorded.

##### Initial State

```
* - task_count = 0
* - All tasks[].registered = k_task_not_registered
* - failed_task[0] = '\0'
*
```

##### Thread Safety

- Registration: Call from single thread during initialization
- Heartbeats: Not thread-safe, caller must synchronize
- Check: Not thread-safe, typically called from single monitoring task

##### Warning

Do not access directly - use API functions

## 7.3.1 Detailed Description

DTC transfer information structure for short-address mode.

Compact format for 16 MB address space transfers. Uses 3-byte addresses to save memory.

## Warning

Must be aligned to 4-byte boundary

## Note

For full-address mode, use `dtc_transfer_info_full_t`

## Since

Version 1.0.0

#include "rx_check.h"
#include "rx_err.h"
#include "rx_infrastructure.h"
#include "rx_log.h"
#include "rx_port_constants.h"
#include "rx_bus_types.h"
```

Include dependency graph for hardware.h:

This graph shows which files directly or indirectly include this file:

#### Data Structures

- struct [riic\\_channel\\_t](#)  
RIIC (I2C) channel wrapper providing strong type safety.
- struct [i2c\\_device\\_addr\\_t](#)  
I2C device address wrapper providing strong type safety.
- struct [rspi\\_config\\_t](#)  
RSPI peripheral mode configuration structure.
- struct [rspi\\_controller\\_config\\_t](#)  
RSPI controller mode configuration structure.
- struct [uart\\_channel\\_config\\_t](#)  
UART channel configuration structure.

## Typedefs

- typedef rx\_adc\_resolution\_t [adc\\_resolution\\_t](#)

## Enumerations

- enum [adc\\_unit\\_t](#) : uint8\_t { [k\\_adc\\_unit\\_0](#) , [k\\_adc\\_unit\\_1](#) }  
ADC unit enumeration with type safety for 12-bit SAR ADC modules.
- enum [adc\\_channel\\_t](#) : uint8\_t {  
[k\\_adc\\_channel\\_0](#) = 0 , [k\\_adc\\_channel\\_1](#) = 1 , [k\\_adc\\_channel\\_2](#) = 2 , [k\\_adc\\_channel\\_3](#) = 3 ,  
[k\\_adc\\_channel\\_4](#) = 4 , [k\\_adc\\_channel\\_5](#) = 5 , [k\\_adc\\_channel\\_6](#) = 6 , [k\\_adc\\_channel\\_7](#) = 7  
}  
ADC channel enumeration with type safety for analog input selection.
- enum [riic\\_peripheral\\_limits\\_t](#) : uint16\_t { [k\\_riic\\_peripheral\\_transfer\\_limit](#) = 256 }  
Public size limits for RIIC peripheral mode callers.
- enum [rspi\\_mode\\_t](#) : uint8\_t { [k\\_rspi\\_mode\\_0](#) , [k\\_rspi\\_mode\\_1](#) , [k\\_rspi\\_mode\\_2](#) = 2 ,  
[k\\_rspi\\_mode\\_3](#) }  
SPI mode enumeration defining clock polarity (CPOL) and phase (CPHA) combinations.
- enum [rspi\\_channel\\_t](#) : uint8\_t { [k\\_rspi\\_channel\\_0](#) = 0 , [k\\_rspi\\_channel\\_1](#) = 1 ,  
[k\\_rspi\\_channel\\_2](#) = 2 }  
RSPI channel enumeration with type safety for SPI peripheral selection.
- enum [rspi\\_freq\\_constants\\_t](#) : uint32\_t { [k\\_rspi\\_freq\\_1mhz](#) = 1000000 , [k\\_rspi\\_freq\\_10mhz](#) = 10000000 }  
Common SPI clock frequency constants for controller mode.
- enum [uart\\_defaults\\_t](#) : uint8\_t { [k\\_uart\\_debug\\_channel](#) = 9 }  
Default debug UART channel (SCI9 - CY7C65213 USB bridge).
- enum [uart\\_channel\\_t](#) : uint8\_t {  
[k\\_uart\\_channel\\_0](#) = 0 , [k\\_uart\\_channel\\_1](#) = 1 , [k\\_uart\\_channel\\_2](#) = 2 , [k\\_uart\\_channel\\_3](#) = 3 ,  
[k\\_uart\\_channel\\_4](#) = 4 , [k\\_uart\\_channel\\_5](#) = 5 , [k\\_uart\\_channel\\_6](#) = 6 , [k\\_uart\\_channel\\_7](#) = 7 ,  
[k\\_uart\\_channel\\_8](#) = 8 , [k\\_uart\\_channel\\_9](#) = 9 , [k\\_uart\\_channel\\_10](#) = 10 , [k\\_uart\\_channel\\_11](#) = 11 ,  
[k\\_uart\\_channel\\_12](#) = 12 }  
UART channel enumeration with type safety.

## Functions

- rx\_err\_t [gpio\\_set\\_output](#) (rx\_port\_pin\_t pin)  
Configure GPIO pin as digital output.
- rx\_err\_t [gpio\\_set\\_input](#) (rx\_port\_pin\_t pin)  
Configure GPIO pin as digital input.
- rx\_err\_t [gpio\\_write\\_high](#) (rx\_port\_pin\_t pin)  
Set GPIO output pin to logic high (VDD).
- rx\_err\_t [gpio\\_write\\_low](#) (rx\_port\_pin\_t pin)  
Set GPIO output pin to logic low (GND).
- rx\_err\_t [gpio\\_toggle](#) (rx\_port\_pin\_t pin)  
Toggle GPIO output pin state (high to low, or low to high).
- rx\_err\_t [gpio\\_read](#) (rx\_port\_pin\_t pin, bool \*value)  
Read current logic level of GPIO pin.
- rx\_err\_t [timer\\_init](#) (void)  
Initialize CMT0 for ThreadX system tick (100 Hz).

- rx\_err\_t [timer\\_stop](#) (void)  
Stop CMT0 timer and disable compare match interrupts.
- rx\_err\_t [timer\\_get\\_count](#) (uint16\_t \*count)  
Get current CMT0 counter value.
- rx\_err\_t [adc\\_init](#) (adc\_unit\_t unit, adc\_channel\_t channel, adc\_resolution\_t bits)  
Initialize ADC unit and channel.
- rx\_err\_t [adc\\_read](#) (adc\_unit\_t unit, adc\_channel\_t channel, uint16\_t \*value)  
Read ADC value.
- rx\_err\_t [adc\\_read\\_voltage\\_mv](#) (adc\_unit\_t unit, adc\_channel\_t channel, adc\_resolution\_t bits, uint32\_t \*voltage\_mv)  
Read ADC value and convert to millivolts.
- rx\_err\_t [riic\\_init](#) (riic\_channel\_t channel, uint32\_t frequency\_hz)  
Initialize RIIC channel for I2C controller communication.
- rx\_err\_t [riic\\_write](#) (riic\_channel\_t channel, i2c\_device\_addr\_t device\_addr, const uint8\_t \*data, uint16\_t length)  
Write data to I2C device on specified RIIC channel.
- rx\_err\_t [riic\\_read](#) (riic\_channel\_t channel, i2c\_device\_addr\_t device\_addr, uint8\_t \*data, uint16\_t length)  
Read data from I2C device on specified RIIC channel.
- rx\_err\_t [riic\\_write\\_read](#) (riic\_channel\_t channel, i2c\_device\_addr\_t device\_addr, const uint8\_t \*write\_data, uint16\_t write\_length, uint8\_t \*read\_data, uint16\_t read\_length)  
Write then read from I2C device using repeated START (combined transaction).
- rx\_err\_t [riic\\_init\\_peripheral](#) (riic\_channel\_t channel, i2c\_device\_addr\_t device\_addr)  
Initialize RIIC channel in peripheral (device) mode.
- rx\_err\_t [riic\\_deinit\\_peripheral](#) (riic\_channel\_t channel)  
Deinitialize an RIIC channel previously initialized in peripheral mode.
- rx\_err\_t [riic\\_peripheral\\_read](#) (riic\_channel\_t channel, uint8\_t \*data, uint16\_t max\_length, uint16\_t \*bytes\_read)  
Read bytes written by the I2C controller to this peripheral.
- rx\_err\_t [riic\\_peripheral\\_write](#) (riic\_channel\_t channel, const uint8\_t \*data, uint16\_t length)  
Write bytes for the I2C controller to read from this peripheral.
- rx\_err\_t [rspi\\_init\\_peripheral](#) (rspi\_channel\_t channel, const rspi\_config\_t \*config)  
Initialize RSPI channel in peripheral mode for RPi5 communication.
- rx\_err\_t [rspi\\_peripheral\\_transfer](#) (rspi\_channel\_t channel, const uint8\_t \*tx\_data, uint8\_t \*rx\_data, uint16\_t length)  
Full-duplex SPI transfer in peripheral mode.
- rx\_err\_t [rspi\\_peripheral\\_read\\_available](#) (rspi\_channel\_t channel, bool \*available)  
Check if receive data is available in the RSPI receive buffer.
- rx\_err\_t [rspi\\_peripheral\\_write\\_ready](#) (rspi\_channel\_t channel, bool \*ready)  
Check if the RSPI transmit buffer is ready for new data.
- rx\_err\_t [rspi\\_deinit](#) (rspi\_channel\_t channel)  
Deinitialize and disable an RSPI peripheral-mode channel.
- rx\_err\_t [rspi\\_init\\_controller](#) (rspi\_channel\_t channel, const rspi\_controller\_config\_t \*config)  
Initialize RSPI channel in controller mode for external device communication.
- rx\_err\_t [rspi\\_controller\\_set\\_cs](#) (rspi\_channel\_t channel, bool active)  
Set chip select line state for an RSPI controller-mode channel.
- rx\_err\_t [rspi\\_controller\\_transfer\\_16bit](#) (rspi\_channel\_t channel, uint16\_t tx\_data, uint16\_t \*rx\_data)  
Perform a 16-bit full-duplex SPI transfer in controller mode with automatic CS.
- rx\_err\_t [rspi\\_controller\\_deinit](#) (rspi\_channel\_t channel)  
Deinitialize and disable an RSPI controller-mode channel.
- rx\_err\_t [uart\\_init\\_channel](#) (const uart\_channel\_config\_t \*config)

- Initialize SCI channel for UART communication.
- rx\_err\_t [uart\\_deinit\\_channel](#) ([uart\\_channel\\_t](#) channel)
- Deinitialize SCI channel.
- rx\_err\_t [uart\\_putc\\_channel](#) ([uart\\_channel\\_t](#) channel, char data)
- Transmit a single character on specified channel.
- rx\_err\_t [uart\\_puts\\_channel](#) ([uart\\_channel\\_t](#) channel, const char \*str)
- Transmit a null-terminated string on specified channel.
- rx\_err\_t [uart\\_write\\_channel](#) ([uart\\_channel\\_t](#) channel, const uint8\_t \*data, uint16\_t length)
- Write buffer to specified channel.
- rx\_err\_t [uart\\_getc\\_channel](#) ([uart\\_channel\\_t](#) channel, char \*data)
- Receive a single character from specified channel (non-blocking).
- rx\_err\_t [uart\\_read\\_channel](#) ([uart\\_channel\\_t](#) channel, uint8\_t \*data, uint16\_t length, uint16\_t \*bytes\_read)
- Read available data from specified channel (non-blocking).
- rx\_err\_t [uart\\_rx\\_available](#) ([uart\\_channel\\_t](#) channel, bool \*available)
- Check if receive data is available on channel.
- rx\_err\_t [uart\\_clear\\_rx\\_errors](#) ([uart\\_channel\\_t](#) channel)
- Clear sticky receive error flags (ORER/FER/PER) on a UART channel.
- rx\_err\_t [uart\\_debug\\_init](#) (void)
- Initialize debug UART (SCI9, 115200 bps, 8N1).
- void [uart\\_debug\\_putc](#) (char data)
- Transmit a single character on debug UART (SCI9).
- void [uart\\_debug\\_puts](#) (const char \*str)
- Transmit a null-terminated string on debug UART (SCI9).
- void [uart\\_debug\\_putint](#) (int32\_t value)
- Print a signed integer on debug UART (SCI9).
- void [uart\\_debug\\_puthex](#) (uint32\_t value, uint8\_t digits)
- Print a hexadecimal value on debug UART (SCI9).

### 8.1.1 Detailed Description

Hardware Abstraction Layer (HAL) - Unified Interface for RX72N Peripherals.

#### 8.1.1.1 Overview

Comprehensive HAL providing type-safe, unified API for all RX72N microcontroller peripherals used in the STAR motor controller. Abstracts hardware register manipulation and provides safe, validated access to GPIO, timers, ADC, I2C, SPI, and UART peripherals.

#### 8.1.1.2 Supported Peripherals

| Peripheral | Channels       | Purpose                            | Configuration                      |
|------------|----------------|------------------------------------|------------------------------------|
| GPIO       | 14 ports (A-N) | Digital I/O, motor control signals | Output/Input, Read/Write/↔ Toggle  |
| CMT        | 4 channels     | ThreadX system tick (100 Hz)       | CMT0 configured for 10ms intervals |

| Peripheral | Channels           | Purpose                                           | Configuration           |
|------------|--------------------|---------------------------------------------------|-------------------------|
| S12AD      | 2 units (0-1)      | Motor current sensing, analog inputs              | 8/10/12-bit resolution  |
| RIIC       | 3 channels (0-2)   | I2C sensors (IMU); temperature sensor uses 1-Wire | 100kHz, 400kHz, 1MHz    |
| RSPI       | 3 channels (0-2)   | SPI: RPi5 comm (peripheral), sensors (controller) | Mode 0-3, 100kHz-10MHz  |
| SCI        | 13 channels (0-12) | UART: Debug (SCI9 @ 115200), expansion            | Configurable baud rates |

### 8.1.1.3 Hardware Architecture

### 8.1.1.4 Key Design Principles

#### 8.1.1.4.1 1. Type Safety (C23 Typed Enums + Struct Wrappers)

- Typed enums: All constants use C23 : `uint8_t` syntax for guaranteed size
- Struct wrappers: I2C channel/address use struct wrappers to prevent argument swaps
- Compile-time validation: Invalid types caught at compile time, not runtime

Example - Type Safety Prevents Bugs:

```

// WRONG - Swapped arguments with plain uint8_t
riic_write(0x48, 0, data, len); // Accidentally swapped channel and address

// CORRECT - Struct wrappers catch this at compile time
riic_channel_t ch = {.value = 0};
i2c_device_addr_t addr = {.value = 0x48};
riic_write(ch, addr, data, len); // Type-checked, no accidental swaps possible

```

#### 8.1.1.4.2 2. Unified Error Handling

- Consistent returns: All functions return `rx_err_t` (except debug helpers)
- Comprehensive error codes: Covers NULL pointers, invalid arguments, timeouts, conflicts
- Validation: All functions validate inputs before hardware access

#### 8.1.1.4.3 3. Configuration Structs Over Positional Parameters

- Maintainability: Adding new config options doesn't break API
- Clarity: Named fields > positional parameters
- Safety: Reduces parameter order mistakes

Example:

```
// OLD STYLE (error-prone):
uart_init(9, 115200, k_port_b_pin_7, k_port_b_pin_6); // Which pin is TX vs RX?

// NEW STYLE (clear and safe):
uart_channel_config_t config = {
 .channel = k_uart_channel_9,
 .baudrate = 115200,
 .tx_gpio = k_port_b_pin_7,
 .rx_gpio = k_port_b_pin_6
};
uart_init_channel(&config); // Self-documenting
```

#### 8.1.1.4.4 4. Zero Dynamic Allocation (NASA Rule 3)

- All functions use stack-based parameters
- No malloc/free anywhere in HAL
- Predictable memory behavior for safety-critical systems

### 8.1.1.5 Performance Characteristics

#### 8.1.1.5.1 Function Call Overhead (RX72N @ 240 MHz)

| Function Category     | Cycles | Time    | Notes                          |
|-----------------------|--------|---------|--------------------------------|
| GPIO write            | ~20    | 83 ns   | Direct register access         |
| GPIO read             | ~25    | 104 ns  | Includes pin validation        |
| UART putc             | ~150   | 625 ns  | Polling TDRE flag              |
| UART puts (10 chars)  | ~1500  | 6.25 us | 150 cycles/char                |
| I2C write (1 byte)    | ~24000 | 100 us  | 400kHz I2C clock               |
| SPI transfer (1 byte) | ~480   | 2 us    | 10 MHz SPI clock               |
| ADC read              | ~7200  | 30 us   | 12-bit conversion + validation |

## 8.1.1.5.2 Memory Footprint

| Component    | Flash  | RAM                 | Stack (max) |
|--------------|--------|---------------------|-------------|
| GPIO drivers | ~2 KB  | 16 bytes (state)    | 32 bytes    |
| UART drivers | ~3 KB  | 128 bytes (buffers) | 48 bytes    |
| I2C drivers  | ~4 KB  | 64 bytes (state)    | 64 bytes    |
| SPI drivers  | ~5 KB  | 96 bytes (state)    | 64 bytes    |
| ADC drivers  | ~2 KB  | 32 bytes (state)    | 32 bytes    |
| Total HAL    | ~16 KB | ~336 bytes          | ~240 bytes  |

## 8.1.1.6 Thread Safety

- NOT thread-safe: Hardware registers are not protected by mutexes
- Single-threaded access: Each peripheral should be accessed from one thread only
- RTOS integration: Use ThreadX mutexes if multi-threaded access needed
- Interrupt safety: All HAL functions disable interrupts during critical sections

## 8.1.1.7 Initialization Sequence

Recommended initialization order for STAR motor controller:

```
void hardware_init(void) {
 // 1. Debug UART (for early logging)
 uart_debug_init();
 rx_log_info("INIT", "Starting hardware initialization");

 // 2. System timer (for ThreadX tick)
 timer_init();

 // 3. GPIO (for motor control signals)
 gpio_set_output(k_port_c_pin_0); // Motor enable
 gpio_set_output(k_port_c_pin_1); // Direction

 // 4. SPI controller (for sensors; DRV8263H uses PWM+GPIO, not SPI)
 rspi_controller_config_t spi_cfg = {
 .spi_mode = k_rspi_mode_0,
 .freq_hz = k_rspi_freq_1mhz,
 .cs = k_port_c_pin_4
 };
 rspi_init_controller(k_rspi_channel_1, &spi_cfg);

 // 5. SPI peripheral (for RPi5 communication)
 rspi_config_t rpi_cfg = {
 .spi_mode = k_rspi_mode_0,
 .use_16bit = false
 };
 rspi_init_peripheral(k_rspi_channel_0, &rpi_cfg);

 // 6. ADC (for motor current sensing on AN007/P47)
 adc_init(k_adc_unit_0, k_adc_channel_7, k_adc_resolution_12bit);

 // 7. I2C (for IMU sensor)
 riic_init((riic_channel_t){.value = 0}, 400000);

 rx_log_info("INIT", "Hardware initialization complete");
}
```

### 8.1.1.8 Pin Assignments (From Project Schematic)

See docs/sections/03\_hardware\_pinout.tex for complete pinout documentation.

Critical Signals:

| Signal    | Pin | Peripheral | Purpose                          |
|-----------|-----|------------|----------------------------------|
| SPI0_CIPO | P30 | RSPI0      | RPi5 <- RX72N (peripheral mode)  |

| UART_RX   | PB6 | SCI9       | Debug input                      |

### 8.1.1.9 Dependencies

- rx\_err.h - Error code definitions
- rx\_check.h - Validation macros
- rx\_log.h - Logging infrastructure
- rx\_port\_constants.h - Port/pin definitions
- rx\_bus\_types.h - Bus enumeration types
- [rx72n\\_regs.h](#) - Hardware register definitions (internal)

NASA Power of 10 Compliance:

- Rule 1 [YES]: No goto, setjmp, recursion (pure validation + register access)
- Rule 2 [YES]: All loops bounded (timeout loops use compile-time max iterations)
- Rule 3 [YES]: No dynamic allocation (all stack-based or static configuration)
- Rule 4 [YES]: All functions <60 lines (HAL functions are typically 20-40 lines)
- \*\*Rule 5 [YES]\*\*: Minimum 2 validations per function (NULL checks + range validation)
- \*\*Rule 6 [YES]\*\*: Data at smallest scope (loop counters, temporary variables)
- \*\*Rule 7 [YES]\*\*: All returns validated (rx\_err\_t checked at every call site)
- \*\*Rule 8 [YES]\*\*: C23 typed enums for constants, minimal preprocessor use
- \*\*Rule 9 [YES]\*\*: Single-level dereferencing (pointer parameters for output values)
- \*\*Rule 10 [YES]\*\*: Compiles with -Wall -Wextra -Werror

SOLID Principles:

- **\*\*S (Single Responsibility):\*\*** Each peripheral has dedicated functions (GPIO, UART, SPI, I2C, ADC)
- **\*\*O (Open/Closed):\*\*** Config structs allow extension without modifying function signatures
- **\*\*L (Liskov Substitution):\*\*** All HAL functions return `rx_err_t` with consistent semantics
- **\*\*I (Interface Segregation):\*\*** Separate controller/peripheral SPI APIs, debug UART wrappers
- **\*\*D (Dependency Inversion):\*\*** Depends on abstract `rx_err_t`, `rx_log`, not concrete implementations

Module Dependencies:

```
hardware.h
+--> rx_err.h (error codes)
+--> rx_check.h (validation macros)
+--> rx_log.h (logging)
+--> rx_port_constants.h (port/pin enums)
+--> rx_bus_types.h (ADC resolution enums)
+--> [internal] rx72n_regs.h (register definitions)
```

Used by:

```
+--> Motor control (rx_motor_control.c)
+--> USB communication (rx_usb.c)
+--> Protocol handling (rx_comm_manager.c)
+--> Application tasks (comm, motor, sensors)
```

## 8.1.2 Data Structure Documentation

### 8.1.2.1 struct `riic_channel_t`

RIIC (I2C) channel wrapper providing strong type safety.

Wraps RIIC channel number in a struct to prevent accidental argument swaps with I2C device addresses. This is a stronger type safety mechanism than simple typedefs because structs cannot be implicitly converted.

### 8.1.2.2 Design Rationale: Struct Wrapper vs. Typedef

Why struct wrapper instead of simple typedef?

I2C functions have multiple `uint8_t` parameters that are easily confused:

- Channel number (0-2)
- Device address (0x00-0x7F)
- Register address (0x00-0xFF)
- Data bytes (0x00-0xFF)

#### 8.1.2.2.1 Problem with Simple Typedefs

```
typedef uint8_t riic_channel_t; // Simple typedef
typedef uint8_t i2c_device_addr_t; // Simple typedef

riic_channel_t ch = 0;
i2c_device_addr_t addr = 0x48;

// PROBLEM: Arguments can be swapped without compiler error!
riic_write(addr, ch, data, len); // Compiles! Wrong order, but types are compatible
```

#### 8.1.2.2.2 Solution with Struct Wrappers

```
typedef struct { uint8_t value; } riic_channel_t; // Struct wrapper
typedef struct { uint8_t value; } i2c_device_addr_t; // Struct wrapper

riic_channel_t ch = {.value = 0};
i2c_device_addr_t addr = {.value = 0x48};

// CORRECT: Compiler catches swapped arguments!
riic_write(addr, ch, data, len); // Compile error: type mismatch!
riic_write(ch, addr, data, len); // Correct order, compiles successfully
```

### 8.1.2.3 Comparison: ADC vs. I2C Type Safety

| Peripheral | Type Safety Mechanism | Rationale                                                    |
|------------|-----------------------|--------------------------------------------------------------|
| ADC        | Simple typed enums    | Parameters are distinct (unit vs channel vs resolution bits) |
| I2C        | Struct wrappers       | Multiple <code>uint8_t</code> parameters easily confused     |
| SPI        | Simple typed enums    | Mode, channel, frequency are distinct types                  |
| UART       | Simple typed enums    | Channel and baudrate are distinct types                      |

ADC: `adc_read(k_adc_unit_0, k_adc_channel_1, &value)` -> Different types prevent swaps I2C:↵  
`riic_write({.value = 0}, {.value = 0x48}, data, len)` -> Struct wrappers prevent swaps

#### 8.1.2.4 RX72N RIIC Hardware

- Channels Available: 3 (RIIC0, RIIC1, RIIC2)
- Speeds: 100 kHz (standard), 400 kHz (fast), 1 MHz (fast-plus)
- Addressing: 7-bit (0x00-0x7F) or 10-bit (not used in STAR project)

## 8.1.2.5 STAR Project Usage

| Channel | SCL Pin | SDA Pin | Device        | Address | Purpose             |
|---------|---------|---------|---------------|---------|---------------------|
| 0       | P16     | P17     | IMU (MPU6050) | 0x68    | Orientation sensing |
| 1       | P54     | P55     | Reserved      | -       | Future expansion    |
| 2       | P52     | P53     | Reserved      | -       | Future expansion    |

## 8.1.2.6 Usage Example

```
#include "hardware.h"

void imu_init(void) {
 // Initialize I2C channel 0 at 400 kHz (fast mode)
 riic_channel_t ch = {.value = 0};
 riic_init(ch, 400000);

 // MPU6050 IMU device address
 i2c_device_addr_t imu_addr = {.value = 0x68};

 // Write to WHO_AM_I register (0x75) to verify device
 uint8_t reg_addr = 0x75;
 uint8_t who_am_i;
 riic_write_read(ch, imu_addr, ®_addr, 1, &who_am_i, 1);

 if (who_am_i == 0x68) {
 rx_log_info("IMU", "MPU6050 detected");
 }
}
```

Example: Compiler Catches Mistakes

```
riic_channel_t ch = {.value = 0};
i2c_device_addr_t addr = {.value = 0x48};
uint8_t data[] = {0x01, 0x02};

// WRONG - Arguments swapped (compiler error!)
riic_write(addr, ch, data, 2);
// Error: cannot convert 'i2c_device_addr_t' to 'riic_channel_t'

// CORRECT - Proper order
riic_write(ch, addr, data, 2); // Compiles successfully
```

## Data Fields

|         |       |                                                             |
|---------|-------|-------------------------------------------------------------|
| uint8_t | value | RIIC channel number (0-2). Use {.value = N} initialization. |
|---------|-------|-------------------------------------------------------------|

## 8.1.2.7 struct i2c\_device\_addr\_t

I2C device address wrapper providing strong type safety.

Wraps 7-bit I2C device address in a struct to prevent accidental swaps with channel numbers or register addresses. Part of the type safety system that uses struct wrappers to catch parameter ordering mistakes at compile time.

## 8.1.2.8 I2C Addressing

- 7-bit addressing: Standard mode used in STAR project
- Valid range: 0x08-0x77 (0x00-0x07 and 0x78-0x7F reserved)
- Reserved addresses:

0x00: General call

0x01-0x07: CBUS, different bus formats

0x78-0x7F: 10-bit addressing, reserved

## 8.1.2.9 Common Device Addresses

| Device              | Address   | Alt Address | Configurable   |
|---------------------|-----------|-------------|----------------|
| MPU6050 (IMU)       | 0x68      | 0x69        | Via AD0 pin    |
| BMP280 (Pressure)   | 0x76      | 0x77        | Via SDO pin    |
| ADS1115 (ADC)       | 0x48-0x4B | -           | Via ADDR pin   |
| PCA9685 (PWM)       | 0x40-0x7F | -           | Via A0-A5 pins |
| EEPROM (24C series) | 0x50-0x57 | -           | Via A0-A2 pins |

## 8.1.2.10 Address Format on Bus

The 7-bit address is shifted left by 1 bit and combined with R/W bit:

[A6 A5 A4 A3 A2 A1 A0 R/W]  
 \\_\_\_\_ 7-bit address \_\_\_\_/ \\_ 0=Write, 1=Read

Note: HAL automatically handles this shifting. Always provide 7-bit address.

## 8.1.2.11 STAR Project Devices

| Device          | Address | Channel | Purpose                |
|-----------------|---------|---------|------------------------|
| MPU6050 IMU     | 0x68    | RIIC0   | 6-axis motion tracking |
| Future sensor 1 | TBD     | RIIC1   | Expansion              |
| Future sensor 2 | TBD     | RIIC2   | Expansion              |

## 8.1.2.12 Usage Example

```
// MPU6050 IMU on RIIC0
riic_channel_t ch = {.value = 0};
i2c_device_addr_t imu_addr = {.value = 0x68};

// Read power management register (0x6B)
uint8_t pwr_mgmt_reg = 0x6B;
uint8_t pwr_mgmt_val;

riic_write_read(ch, imu_addr, &pwr_mgmt_reg, 1, &pwr_mgmt_val, 1);
rx_log_info_hex("IMU", "Power management", pwr_mgmt_val, 2);
```

## Example: Multi-Device Bus

```
// Multiple devices on same I2C bus
riic_channel_t ch = {.value = 0};

i2c_device_addr_t imu_addr = {.value = 0x68}; // MPU6050
i2c_device_addr_t baro_addr = {.value = 0x76}; // BMP280
i2c_device_addr_t adc_addr = {.value = 0x48}; // ADS1115

// Read from different devices on same bus
uint8_t imu_data[6];
riic_read(ch, imu_addr, imu_data, 6);

uint8_t baro_data[3];
riic_read(ch, baro_addr, baro_data, 3);

uint8_t adc_data[2];
riic_read(ch, adc_addr, adc_data, 2);
```

## Data Fields

|                      |       |                                                                                        |
|----------------------|-------|----------------------------------------------------------------------------------------|
| <code>uint8_t</code> | value | 7-bit I2C device address (0x08-0x77). Use <code>{.value = 0xNN}</code> initialization. |
|----------------------|-------|----------------------------------------------------------------------------------------|

8.1.2.13 `struct rspi_config_t`

RSPI peripheral mode configuration structure.

Configuration parameters for initializing an RSPI channel in peripheral mode. Used when the RX72N acts as an SPI peripheral device, receiving clock from an external controller (e.g., Raspberry Pi 5). The struct encapsulates SPI mode and frame size settings to avoid positional parameter errors.

```
rspi_config_t rpi_cfg = {
 .spi_mode = k_rspi_mode_0, // CPOL=0, CPHA=0
 .use_16bit = false // 8-bit frame size
};
```

## Invariant

`spi_mode` must be a valid [rspi\\_mode\\_t](#) value (0-3, CPOL/CPHA combinations)

`use_16bit` is boolean: false for 8-bit frames, true for 16-bit frames

## See also

|------|-----------|------------------------------------------------|
| bool | use_16bit | True for 16-bit frames, false for 8-bit frames |
|------|-----------|------------------------------------------------|

#### 8.1.2.14 struct rspi\_controller\_config\_t

RSPI controller mode configuration structure.

Configuration for initializing RSPI in controller mode. Used for communicating with SPI peripheral devices (sensors, etc.).

Definition at line 2098 of file [hardware.h](#).

Collaboration diagram for rspi\_controller\_config\_t:

#### Data Fields

|                            |                       |                                               |
|----------------------------|-----------------------|-----------------------------------------------|
| <code>rx_port_pin_t</code> | <code>cs</code>       | GPIO pin for chip select (type-safe port+pin) |
| <code>uint32_t</code>      | <code>freq_hz</code>  | SPI clock frequency in Hz (100kHz - 10MHz)    |
| <code>rspi_mode_t</code>   | <code>spi_mode</code> | SPI mode (0-3): CPOL and CPHA configuration   |

#### 8.1.2.15 struct uart\_channel\_config\_t

UART channel configuration structure.

Encapsulates all parameters needed to initialize a UART channel. Using a struct instead of positional parameters prevents accidental parameter swapping and makes the API more maintainable.

Definition at line 2332 of file [hardware.h](#).

Collaboration diagram for uart\_channel\_config\_t:

## Data Fields

|                |          |                                |
|----------------|----------|--------------------------------|
| uint32_t       | baudrate | Baud rate (e.g., 9600, 115200) |
| uart_channel_t | channel  | SCI channel (0-12)             |
| rx_port_pin_t  | rx_gpio  | RX pin (rx_port_pin_t)         |
| rx_port_pin_t  | tx_gpio  | TX pin (rx_port_pin_t)         |

## 8.1.3 Typedef Documentation

## 8.1.3.1 adc\_resolution\_t

```
typedef rx_adc_resolution_t adc_resolution_t
```

Definition at line 966 of file [hardware.h](#).

## 8.1.4 Enumeration Type Documentation

## 8.1.4.1 adc\_channel\_t

```
enum adc_channel_t : uint8_t
```

ADC channel enumeration with type safety for analog input selection.

Identifies which analog input channel (0-7) to use within an ADC unit. Each unit (S12AD0, S12AD1) has 8 independent channels with dedicated analog input pins. Using a typed enum prevents accidental parameter swaps with unit or resolution.

## 8.1.4.2 Pin Mapping (RX72N 144-pin LQFP, R5F572NNHxFB)

## 8.1.4.2.1 S12AD0 Channels (use with k\_adc\_unit\_0)

| Channel         | Pin | Signal Name | STAR Usage            |
|-----------------|-----|-------------|-----------------------|
| k_adc_channel_0 | P40 | AN000       | Available (expansion) |
| k_adc_channel_1 | P41 | AN001       | Available (expansion) |
| k_adc_channel_2 | P42 | AN002       | Available (expansion) |
| k_adc_channel_3 | P43 | AN003       | Available (expansion) |
| k_adc_channel_4 | P44 | AN004       | Motor 3 current sense |
| k_adc_channel_5 | P45 | AN005       | Motor 2 current sense |

| Channel         | Pin | Signal Name | STAR Usage            |
|-----------------|-----|-------------|-----------------------|
| k_adc_channel_6 | P46 | AN006       | Motor 1 current sense |
| k_adc_channel_7 | P47 | AN007       | Motor 0 current sense |

#### 8.1.4.3 Input Specifications

- Voltage Range: 0V to AVCC (3.3V)
- Input Impedance: 1 MOhm typical
- Max Input Current: +/-10 uA
- Protection: Internal clamping diodes to AVCC/AVSS

#### 8.1.4.4 Usage Example

```
// Motor current sensing
adc_init(k_adc_unit_0, k_adc_channel_0, k_adc_resolution_12bit);

uint32_t voltage_mv;
adc_read_voltage_mv(k_adc_unit_0, k_adc_channel_0, k_adc_resolution_12bit, &voltage_mv);
rx_log_info_val("ADC", "Current sense (mV)", voltage_mv);
```

Underlying Type: uint8\_t (C23 typed enum)

- Range: 0-7 (8 channels per unit)
- Size: 1 byte
- Rationale: Matches hardware channel select bits (ADANSA register)

#### Enumerator

|                 |                                                                   |
|-----------------|-------------------------------------------------------------------|
| k_adc_channel_0 | Channel 0 - AN000 (unit 0) or AN100 (unit 1). Available.          |
| k_adc_channel_1 | Channel 1 - AN001 (unit 0) or AN101 (unit 1). Available.          |
| k_adc_channel_2 | Channel 2 - AN002 (unit 0) or AN102 (unit 1). Available.          |
| k_adc_channel_3 | Channel 3 - AN003 (unit 0) or AN103 (unit 1). Available.          |
| k_adc_channel_4 | Channel 4 - AN004/P44 (unit 0, Motor 3 current) or AN104 (unit 1) |

|                 |                                                                   |
|-----------------|-------------------------------------------------------------------|
| k_adc_channel_5 | Channel 5 - AN005/P45 (unit 0, Motor 2 current) or AN105 (unit 1) |
| k_adc_channel_6 | Channel 6 - AN006/P46 (unit 0, Motor 1 current) or AN106 (unit 1) |
| k_adc_channel_7 | Channel 7 - AN007/P47 (unit 0, Motor 0 current) or AN107 (unit 1) |

Definition at line 954 of file [hardware.h](#).

```

00954 : uint8_t {
00955 k_adc_channel_0 = 0, /**< Channel 0 - AN000 (unit 0) or AN100 (unit 1). Available. */
00956 k_adc_channel_1 = 1, /**< Channel 1 - AN001 (unit 0) or AN101 (unit 1). Available. */
00957 k_adc_channel_2 = 2, /**< Channel 2 - AN002 (unit 0) or AN102 (unit 1). Available. */
00958 k_adc_channel_3 = 3, /**< Channel 3 - AN003 (unit 0) or AN103 (unit 1). Available. */
00959 k_adc_channel_4 = 4, /**< Channel 4 - AN004/P44 (unit 0, Motor 3 current) or AN104 (unit 1) */
00960 k_adc_channel_5 = 5, /**< Channel 5 - AN005/P45 (unit 0, Motor 2 current) or AN105 (unit 1) */
00961 k_adc_channel_6 = 6, /**< Channel 6 - AN006/P46 (unit 0, Motor 1 current) or AN106 (unit 1) */
00962 k_adc_channel_7 = 7, /**< Channel 7 - AN007/P47 (unit 0, Motor 0 current) or AN107 (unit 1) */
00963 } adc_channel_t;

```

#### 8.1.4.5 adc\_unit\_t

```
enum adc_unit_t : uint8_t
```

ADC unit enumeration with type safety for 12-bit SAR ADC modules.

Identifies which of the two independent 12-bit successive approximation ADC units (S12AD) on the RX72N to use. Each unit has separate channels, registers, and conversion control. Using a typed enum prevents accidental swapping of unit and channel parameters.

#### 8.1.4.6 Hardware Specifications

| Unit   | Base Address | Channels Available | Max Sample Rate |
|--------|--------------|--------------------|-----------------|
| S12AD0 | 0x00089000   | 8 (AN000-AN007)    | 1 Msps          |
| S12AD1 | 0x00089100   | 21 (AN100-AN120)   | 1 Msps          |

#### 8.1.4.7 STAR Project Usage (144-pin LFQFP)

| Unit              | Channel              | Pin | Signal   | Purpose                                 |

## 8.1.4.8 Type Safety Benefit

```
// WRONG - Easy to swap unit and channel with plain uint8_t
adc_read(0, 1, &value); // Is 0 the unit or channel?

// CORRECT - Typed enums make intent clear
adc_read(k_adc_unit_0, k_adc_channel_1, &value); // Unambiguous
```

Underlying Type: `uint8_t` (C23 typed enum)

- Range: 0-1 (only 2 units on RX72N)
- Size: 1 byte
- Rationale: Smallest type sufficient, explicit size guarantees ABI stability

00904 } adc_unit_t;
```

8.1.4.9 `riic_peripheral_limits_t`

enum [riic\\_peripheral\\_limits\\_t](#) : `uint16_t`

Public size limits for RIIC peripheral mode callers.

Exposes the I/O size ceiling enforced by [riic\\_peripheral\\_read\(\)](#) and [riic\\_peripheral\\_write\(\)](#) so that callers can statically size their buffers and validate arguments without needing to inspect the driver implementation.

See also

[riic\\_peripheral\\_read\(\)](#) Enforces this limit on `max_length`  
[riic\\_peripheral\\_write\(\)](#) Enforces this limit on `length`

|-----------------------------------------------|-------------------------------------------------|
| <code>k_riic_peripheral_transfer_limit</code> | Maximum bytes per peripheral read or write call |
|-----------------------------------------------|-------------------------------------------------|

Definition at line 1511 of file [hardware.h](#).

```
01511 : uint16_t {
01512 k_riic_peripheral_transfer_limit = 256, /**< Maximum bytes per peripheral read or write call */
01513 } riic_peripheral_limits_t;
```

#### 8.1.4.10 `rspi_channel_t`

```
enum rspi_channel_t : uint8_t
```

RSPI channel enumeration with type safety for SPI peripheral selection.

Identifies which of the three RSPI channels (RSPI0, RSPI1, RSPI2) on the RX72N to use. Using a typed enum instead of plain `uint8_t` prevents accidental argument swaps and provides compile-time validation of channel numbers.

#### 8.1.4.11 RX72N RSPI Channel Assignments (STAR Project)

| Channel | Role       | Connected Device   | Pins                                        |
|---------|------------|--------------------|---------------------------------------------|
| RSPI0   | Peripheral | Raspberry Pi 5     | P30 (CIPO), P31 (COPI), P32 (CLK), P33 (CS) |
| RSPI1   | Controller | Reserved (sensors) | PC5 (CIPO), PC6 (COPI), PC7 (CLK)           |
| RSPI2   | Unused     | -                  | -                                           |

Underlying Type: `uint8_t` (C23 typed enum)

- Range: 0-2 (3 channels on RX72N)
- Size: 1 byte

Invariant

Values must be in range `[0, 2]` corresponding to RSPI0, RSPI1, RSPI2

```
// Initialize RSPI channel as peripheral
rspi_config_t cfg = { .spi_mode = k_rspi_mode_0, .use_16bit = false };
rx_err_t err = rspi_init_peripheral(k_rspi_channel_0, &cfg);
```

01807 k_rspi_channel_0 = 0, /**< RSPI0 - RPi5 communication (peripheral mode in STAR project) */
01808 k_rspi_channel_1 = 1, /**< RSPI1 - External sensor SPI (controller mode, reserved) */
01809 k_rspi_channel_2 = 2 /**< RSPI2 - Unused (available for expansion) */
01810 } rspi_channel_t;
```

#### 8.1.4.12 rspi`freq`constants`t

```
enum rspi_freq_constants_t : uint32_t
```

Common SPI clock frequency constants for controller mode.

Named constants for commonly used SPI clock frequencies. Use these instead of magic literals when configuring controller-mode SPI clock rate. The RSPI bit rate register (SPBR) is calculated from these values and the peripheral clock (PCLKB).

Invariant

All values must be positive and expressible by the SPBR register

02088 k_rspi_freq_1mhz = 1000000, /**< 1 MHz SPI clock frequency */
02089 k_rspi_freq_10mhz = 10000000, /**< 10 MHz SPI clock frequency (RPi5 link) */
02090 } rspi_freq_constants_t;
```

#### 8.1.4.13 `rspi_mode_t`

enum `rspi_mode_t` : `uint8_t`

SPI mode enumeration defining clock polarity (CPOL) and phase (CPHA) combinations.

Defines the four standard SPI modes based on clock polarity and phase settings. These modes determine when data is sampled relative to the clock edge and what the idle state of the clock line is.

#### 8.1.4.14 SPI Mode Definitions

| Mode | CPOL | CPHA | Clock Idle | Data Sampled | Data Shifted | Common Devices     |
|------|------|------|------------|--------------|--------------|--------------------|
| 0    | 0    | 0    | Low        | Rising edge  | Falling edge | RPi5, most sensors |
| 1    | 0    | 1    | Low        | Falling edge | Rising edge  | SD cards           |
| 2    | 1    | 0    | High       | Falling edge | Rising edge  | Rare               |
| 3    | 1    | 1    | High       | Rising edge  | Falling edge | Rare               |

#### 8.1.4.15 STAR Project Usage

| Peripheral                  | Mode   | Rationale                                   |
|-----------------------------|--------|---------------------------------------------|
| RPi5 (RSPI0 peripheral)     | Mode 0 | Linux spidev default, maximum compatibility |
| RSPI1 controller (not used) | TBD    | RSPI1 not used in current design            |

#### 8.1.4.16 Clock Polarity (CPOL)

- CPOL=0: Clock idle state is low (GND). Clock starts low, pulses high.
- CPOL=1: Clock idle state is high (VDD). Clock starts high, pulses low.

#### 8.1.4.17 Clock Phase (CPHA)

- CPHA=0: Data sampled on leading clock edge, shifted on trailing edge.
- CPHA=1: Data shifted on leading clock edge, sampled on trailing edge.

#### 8.1.4.18 Timing Diagrams

##### 8.1.4.18.1 Mode 0 (CPOL=0, CPHA=0) - Most Common

```

CLK: ____/---____/---____
COP: ===[D0]===[D1]===
CIP: ===[D0]===[D1]===
 ^ Sample ^ Sample

```

##### 8.1.4.18.2 Mode 3 (CPOL=1, CPHA=1)

```

CLK: ---____/---____/---
COP: ===[D0]===[D1]===
CIP: ===[D0]===[D1]===
 ^ Sample ^ Sample

```

## 8.1.4.19 Selection Guidelines

1. Check device datasheet: Most devices specify preferred mode
2. Mode 0 default: Use Mode 0 if device supports multiple modes
3. Controller/Peripheral match: Both sides must use same mode
4. Avoid Modes 1 and 2: Less common, higher chance of incompatibility

## 8.1.4.20 Hardware Configuration

- SPCR.CPOL bit: Set for CPOL=1, clear for CPOL=0
- SPCR.CPHA bit: Set for CPHA=1, clear for CPHA=0
- Both configurable: HAL automatically sets registers based on mode

## 8.1.4.21 Usage Example

```
// RPi5 communication (peripheral mode, Mode 0)
rspi_config_t rpi_cfg = {
 .spi_mode = k_rspi_mode_0, // CPOL=0, CPHA=0
 .use_16bit = false
};
rspi_init_peripheral(k_rspi_channel_0, &rpi_cfg);

// External sensor communication (controller mode, Mode 0)
rspi_controller_config_t sensor_cfg = {
 .spi_mode = k_rspi_mode_0, // Standard SPI mode 0
 .freq_hz = k_rspi_freq_1mhz, // 1 MHz
 .cs = k_port_c_pin_4
};
rspi_init_controller(k_rspi_channel_1, &sensor_cfg); // RSPI1
```

Underlying Type: uint8\_t (C23 typed enum)

- Range: 0-3 (4 SPI modes)
- Size: 1 byte
- Rationale: Matches SPCR register bit pattern (CPOL | (CPHA << 1))

```

#### 8.1.4.22 uart\_channel\_t

```
enum uart_channel_t : uint8_t
```

UART channel enumeration with type safety.

Prevents accidental argument swaps and provides compile-time type checking. RX72N has SCI channels 0-12 (13 channels total).

Enumerator

|                   |  |
|-------------------|--|
| k_uart_channel_0  |  |
| k_uart_channel_1  |  |

| k_uart_debug_channel | Debug UART on SCI9 (PB7/TXD9, PB6/RXD9) |
|----------------------|-----------------------------------------|

Definition at line [2299](#) of file [hardware.h](#).

```

02299 : uint8_t {
02300 k_uart_debug_channel = 9 /**< Debug UART on SCI9 (PB7/TXD9, PB6/RXD9) */
02301 } uart_defaults_t;

```

### 8.1.5 Function Documentation

#### 8.1.5.1 adc\_init()

```

rx_err_t adc_init (
 const adc_unit_t unit,
 const adc_channel_t channel,
 const adc_resolution_t bits) [nodiscard]

```

Initialize ADC unit and channel.

Parameters

|    |         |                                |
|----|---------|--------------------------------|
| in | unit    | ADC unit (0 or 1)              |
| in | channel | ADC channel (0-7)              |
| in | bits    | Resolution (8, 10, or 12 bits) |

Returns

k\_rx\_ok on success, k\_rx\_err\_invalid\_arg if unit, channel, or bits is invalid, k\_rx\_err\_gpio\_conflict if pin already reserved

Initialize ADC unit and channel.

Configures the S12ADFa peripheral for A/D conversion. On first call for each unit, enables the module clock, configures resolution, and initializes the hardware. Subsequent calls to the same unit enable additional channels.

## 8.1.5.2 Initialization Behavior

| Scenario                        | Action              | Resolution    | Result               |
|---------------------------------|---------------------|---------------|----------------------|
| First init for unit             | Full init           | Set to 'bits' | k_rx_ok              |
| Subsequent init, same bits      | Enable channel only | Unchanged     | k_rx_ok              |
| Subsequent init, different bits | Error               | Unchanged     | k_rx_err_invalid_arg |

## Precondition

None (can be first call for unit)

Resolution must match if unit already initialized

## Postcondition

Module clock enabled (if first init)

Channel enabled in ADANSA register

Unit marked as initialized

## Note

NOT thread-safe: Call from initialization code only

Performance: ~1-2 us for first init, ~0.5 us for subsequent

## Example:

```
// Initialize ADC unit 0, channel 2 with 12-bit resolution
rx_err_t err = adc_init(k_adc_unit_0, k_adc_channel_2, k_adc_resolution_12bit);
if (err != k_rx_ok) {
 rx_log_error("SENSOR", "ADC init failed: %d", err);
 return err;
}
```

## See also

Here is the call graph for this function:

### 8.1.5.3 `adc_read()`

```
rx_err_t adc_read (
 const adc_unit_t unit,
 const adc_channel_t channel,
 uint16_t * value) [nodiscard]
```

Read ADC value.

Parameters

|     |         |                            |
|-----|---------|----------------------------|
| in  | unit    | ADC unit (0 or 1)          |
| in  | channel | ADC channel (0-7)          |
| out | value   | Pointer to store ADC value |

Returns

`k_rx_ok` on success, `k_rx_err_null_ptr` if value is nullptr, `k_rx_err_invalid_arg` if unit or channel is invalid, `k_rx_err_invalid_state` if ADC unit not initialized, `k_rx_err_timeout` if conversion times out

Read ADC value.

Performs a single-scan A/D conversion and returns the raw digital value. This is a blocking operation that polls the ADST bit until conversion completes or timeout occurs.

### 8.1.5.4 Conversion Sequence

1. Validate parameters and initialization state
2. Start conversion by setting ADCSR.ADST bit
3. Poll ADCSR.ADST until cleared (conversion complete)
4. Read result from appropriate ADDRn register

### 8.1.5.5 Output Value Ranges

| Resolution | Range  | Full-Scale |
|------------|--------|------------|
| 12-bit     | 0-4095 | 3.3V       |
| 10-bit     | 0-1023 | 3.3V       |
| 8-bit      | 0-255  | 3.3V       |

Precondition

ADC unit must be initialized via `adc_init()`  
 value must point to valid `uint16_t` storage

## Postcondition

\*value contains raw ADC reading (if k\_rx\_ok)  
 ADC ready for next conversion

## Note

NOT thread-safe: Caller must synchronize if shared  
 Blocking: Waits up to ~100ms for conversion  
 Performance: ~1-10 us typical (depends on conversion time)

## Warning

Do not call from ISR (blocking wait)

## Example:

```
uint16_t raw_value;
rx_err_t err = adc_read(k_adc_unit_0, k_adc_channel_2, &raw_value);
if (err == k_rx_ok) {
 // Example: 12-bit resolution (0-4095 raw -> 0-3.3 V)
 static const float s_vref_volts = 3.3F;
 static const float s_adc_full_scale_12bit = 4095.0F;
 float voltage_v = (raw_value * s_vref_volts) / s_adc_full_scale_12bit;
}
```

Here is the call graph for this function:

Here is the caller graph for this function:

#### 8.1.5.6 `adc_read_voltage_mv()`

```

rx_err_t adc_read_voltage_mv (
 const adc_unit_t unit,
 adc_channel_t channel,
 adc_resolution_t bits,
 uint32_t * voltage_mv) [nodiscard]

```

Read ADC value and convert to millivolts.

## Parameters

|     |            |                                            |
|-----|------------|--------------------------------------------|
| in  | unit       | ADC unit (0 or 1)                          |
| in  | channel    | ADC channel (0-7)                          |
| in  | bits       | Resolution used during init (8, 10, or 12) |
| out | voltage_mv | Pointer to store voltage in millivolts     |

## Returns

k\_rx\_ok on success, k\_rx\_err\_null\_ptr if voltage\_mv is nullptr, k\_rx\_err\_invalid\_arg if unit or channel is invalid, k\_rx\_err\_invalid\_state if ADC unit not initialized, k\_rx\_err\_timeout if conversion times out

Performs an A/D conversion and scales the result to millivolts. This is a convenience function that calls [adc\\_read\(\)](#) and applies the voltage calculation formula.

## 8.1.5.7 Voltage Calculation Formula

$$V_{mV} = \frac{V_{raw} \times 3300}{2^{bits} - 1}$$

## 8.1.5.8 Example Calculations

| Resolution | Raw Value | Voltage (mV) | Calculation        |
|------------|-----------|--------------|--------------------|
| 12-bit     | 2048      | 1650         | 2048 x 3300 / 4095 |
| 10-bit     | 512       | 1650         | 512 x 3300 / 1023  |
| 8-bit      | 128       | 1655         | 128 x 3300 / 255   |

## Precondition

ADC unit must be initialized via [adc\\_init\(\)](#)

bits must match the resolution used in [adc\\_init\(\)](#)

## Postcondition

\*voltage\_mv contains voltage in millivolts (0-3300)

ADC ready for next conversion

## Note

NOT thread-safe: Caller must synchronize if shared

Blocking: Waits for conversion (see [adc\\_read](#))

Reference: Uses 3.3V reference (k\_adc\_reference\_voltage\_mv = 3300)

Example:

```
// Read motor current sense (DRV8263H IPROPI output)
uint32_t voltage_mv;
rx_err_t err = adc_read_voltage_mv(k_adc_unit_0, k_adc_channel_0,
 k_adc_resolution_12bit, &voltage_mv);

if (err == k_rx_ok) {
 // voltage_mv: 0-3300 mV
 // For DRV8263H-Q1 IPROPI (202 uA/A mirror, 5100 Ohm sense):
 // I_motor = V_IPROPI / k_ipropi_divisor
 // (where k_ipropi_divisor = 1.0302 = 202e-6 * 5100)
 // Fixed-point: scale = 10000, divisor = 10302 (1.0302 * 10000)
 enum : uint32_t { k_scale = 10000, k_divisor = 10302 };
 uint32_t current_ma = (voltage_mv * k_scale) / k_divisor;
 rx_log_info("ADC", "Current: %lu mA", current_ma);
}
```

Here is the call graph for this function:

#### 8.1.5.9 gpio\_read()

```

rx_err_t gpio_read (
 const rx_port_pin_t pin,
 bool * value) [nodiscard]

```

Read current logic level of GPIO pin.

Reads the current logic level from the specified GPIO pin's Port Input Data Register (PIDR). Works for both input and output pins. For output pins, reads back the actual pin state (not the output register), which may differ if external circuitry pulls the pin.

#### 8.1.5.10 Algorithm

1. Validate pin parameter (port exists, pin number valid)
2. Validate value pointer (NULL check)
3. Extract port letter and pin number from rx\_port\_pin\_t
4. Read PIDR register for the specified port
5. Extract bit corresponding to pin number
6. Store result (true if bit=1, false if bit=0) in value pointer

#### 8.1.5.11 Performance

- Cycles: ~25 @ 240 MHz
- Time: ~104 ns
- Stack: 8 bytes (pin extraction, register read)

## Parameters

|     |       |                                                                                                                                                                                                                                                                                         |
|-----|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| in  | pin   | GPIO pin identifier from rx_port_constants.h <ul style="list-style-type: none"> <li>• Type: rx_port_pin_t (C23 typed enum)</li> <li>• Format: k_port_X_pin_Y (X = A-N, Y = 0-7)</li> <li>• Can be input or output pin</li> </ul>                                                        |
| out | value | Pointer to boolean for storing pin state <ul style="list-style-type: none"> <li>• Must point to valid bool variable</li> <li>• Set to true if pin reads logic high (VDD)</li> <li>• Set to false if pin reads logic low (GND)</li> <li>• Unchanged if function returns error</li> </ul> |

## Returns

rx\_err\_t Error code indicating success or failure

## Return values

|                            |                                                  |
|----------------------------|--------------------------------------------------|
| k_rx_ok                    | Pin level successfully read and stored in *value |
| k_rx_err_gpio_invalid_port | Port letter out of range (not A-N)               |
| k_rx_err_gpio_invalid_pin  | Pin number out of range (not 0-7)                |
| k_rx_err_null_ptr          | value pointer is nullptr                         |

## Precondition

value pointer must be valid (not nullptr)

## Postcondition

\*value contains current pin state if function succeeds

\*value unchanged if function returns error

## Note

Thread Safety: NOT thread-safe. Reading PIDR register is atomic but value pointer access is not protected.

Output Pins: For output pins, this reads the actual pin level (PIDR), not the output register (PODR). This detects external pull-up/pull-down or short circuits.

Input Pins: Ensure pin is configured as input via [gpio\\_set\\_input\(\)](#) before reading for sensor/button inputs.

## Example: Reading Button State

```
#include "hardware.h"

void check_button(void) {
 // Button connected to Port E Pin 5 (active low with pull-up)
 bool button_state;
 rx_err_t err = gpio_read(k_port_e_pin_5, &button_state);

 if (err != k_rx_ok) {
 rx_log_error_val("BUTTON", "Failed to read button", err);
 return;
 }

 if (!button_state) { // Active low (button pressed)
 rx_log_info("BUTTON", "Button pressed");
 handle_button_press();
 }
}
```

## Example: Verifying Output State

```
// Set motor enable high
gpio_write_high(k_port_c_pin_0);

// Verify pin actually went high (detects short circuit)
bool actual_state;
gpio_read(k_port_c_pin_0, &actual_state);
if (!actual_state) {
 rx_log_error("MOTOR", "Enable pin stuck low - possible short circuit");
 emergency_shutdown();
}
```

## Example: Polling Multiple Inputs

```
typedef struct {
 rx_port_pin_t pin;
 const char* name;
} sensor_input_t;

void poll_sensors(void) {
 const sensor_input_t sensors[] = {
 {k_port_a_pin_0, "LIMIT_SWITCH_1"},
 {k_port_a_pin_1, "LIMIT_SWITCH_2"},
 {k_port_a_pin_2, "ESTOP"}
 };

 for (uint8_t i = 0; i < 3; i++) {
 bool state;
 if (gpio_read(sensors[i].pin, &state) == k_rx_ok) {
 rx_log_debug_val(sensors[i].name, "State", state ? 1 : 0);
 }
 }
}
```

See also

[gpio\\_set\\_input\(\)](#) Configure pin as digital input  
[gpio\\_set\\_output\(\)](#) Configure pin as digital output  
[gpio\\_write\\_high\(\)](#) Set output pin to logic high  
[gpio\\_write\\_low\(\)](#) Set output pin to logic low

Read current logic level of GPIO pin.

Reads the current logic level of a GPIO pin. Uses the PIDR (Port Input Data Register) which reflects the actual voltage level on the pin, regardless of whether the pin is configured as input or output.

## 8.1.5.12 Register Operation

```
value = (PIDR & (1 « pin)) != 0
```

### 8.1.5.13 Input vs Output Reading

- Input pin: PIDR reflects external voltage on pin
- Output pin: PIDR reflects actual pin state (may differ from PODR if pin is shorted or overdriven)

### 8.1.5.14 Voltage Thresholds (RX72N)

| Level     | Voltage Range | Returned Value |
|-----------|---------------|----------------|
| Low       | 0V to ~0.8V   | false          |
| High      | ~2.0V to VCC  | true           |
| Undefined | 0.8V to 2.0V  | Unpredictable  |

#### Precondition

value must be non-nullptr

Pin should be configured as input for external signals

#### Postcondition

\*value contains current pin level (true=high, false=low)

No hardware state changes

#### Note

Thread-safe: Read-only operation

Performance: ~100 ns @ 240 MHz

ISR-safe: Can be called from interrupt handlers

#### Warning

Floating inputs may return unpredictable values

Use pull-up/pull-down for stable readings on open pins

#### Example:

```
// Read button state (active low with pull-up)
bool button_pressed;
rx_err_t err = gpio_read(RX_PORT_PIN(2, 0), &button_pressed);

if (err == k_rx_ok) {
 // Invert because button is active low
 if (!button_pressed) {
 rx_log_info("BTN", "Button pressed");
 handle_button_press();
 }
}
```

Example: Debounced button read

```
bool debounced_read(rx_port_pin_t pin) {
 bool first, second;
 gpio_read(pin, &first);
 tx_thread_sleep(1); // 1 tick delay
 gpio_read(pin, &second);
 return (first == second) ? first : false; // Only return if stable
}
```

#### 8.1.5.15 gpio\_set\_input()

```
rx_err_t gpio_set_input (
 const rx_port_pin_t pin) [nodiscard]
```

Configure GPIO pin as digital input.

Configures the specified GPIO pin as a digital input with high-impedance state. Performs full hardware initialization including port direction register (PDR), port mode register (PMR), and input buffer control. Validates pin assignment and checks for peripheral conflicts.

## 8.1.5.16 Algorithm

1. Validate pin parameter (port exists, pin number valid)
2. Check pin is not already reserved by another peripheral
3. Unlock port write protection (PWPR register)
4. Set PMR bit to 0 (GPIO mode, not peripheral function)
5. Set PDR bit to 0 (input direction)
6. Enable input buffer (ICR register)
7. Lock port write protection
8. Mark pin as reserved in allocation tracker

## Parameters

| in | pin | GPIO pin identifier from rx_port_constants.h                                                                                                                                                                                                                             |
|----|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    |     | <ul style="list-style-type: none"> <li>• Type: rx_port_pin_t (C23 typed enum)</li> <li>• Format: k_port_X_pin_Y (X = A-N, Y = 0-7)</li> <li>• Example: k_port_e_pin_5 (Port E, Pin 5)</li> <li>• Range: All valid combinations defined in rx_port_constants.h</li> </ul> |

## Returns

rx\_err\_t Error code indicating success or failure

## Return values

|                            |                                                             |
|----------------------------|-------------------------------------------------------------|
| k_rx_ok                    | Pin successfully configured as input                        |
| k_rx_err_gpio_invalid_port | Port letter out of range (not A-N)                          |
| k_rx_err_gpio_invalid_pin  | Pin number out of range (not 0-7)                           |
| k_rx_err_gpio_conflict     | Pin already reserved by UART, SPI, I2C, or other peripheral |

## Precondition

- Pin must not be currently in use by another peripheral
- Pin must correspond to a valid physical pin on the RX72N package

## Postcondition

- Pin configured as high-impedance input with input buffer enabled
- Pin marked as reserved in internal allocation tracker

Note

Thread Safety: NOT thread-safe. Do not call concurrently from multiple threads.

Example: Button Input

```
#include "hardware.h"

void button_init(void) {
 rx_err_t err = gpio_set_input(k_port_e_pin_5);
 if (err != k_rx_ok) {
 rx_log_error_val("BTN", "Failed to configure button pin", err);
 return;
 }
 rx_log_info("BTN", "Button input configured");
}
```

See also

[gpio\\_set\\_output\(\)](#) Configure pin as digital output

[gpio\\_read\(\)](#) Read pin logic level

Since

Version 1.0.0

Configures a GPIO pin for digital input mode. This function performs:

1. Parameter validation (port and pin number)
2. Pin reservation via the global pin validator (conflict detection)
3. PMR register clear (select GPIO mode instead of peripheral function)
4. PDR register clear (configure as input direction)

#### 8.1.5.17 Register Operations

```
PMR &= ~(1 « pin) // Clear bit: Select GPIO mode (not peripheral)
PDR &= ~(1 « pin) // Clear bit: Configure as input
```

#### 8.1.5.18 Pull-up Configuration

This function does NOT configure internal pull-up resistors. To enable pull-ups, additional configuration of the PCR register is required.

### 8.1.5.19 Reading Input State

After configuration, use `gpio_read()` to read the current pin state. The PIDR register is read for input state, not PODR.

#### Precondition

- Pin must be a valid GPIO-capable pin on RX72N
- System infrastructure should be initialized (for pin validation)

#### Postcondition

- Pin is configured as GPIO input
- PMR bit for pin is cleared (GPIO mode)
- PDR bit for pin is cleared (input direction)
- Pin is reserved in validator (if available)

#### Note

- Thread-safe: Pin reservation uses mutex
- Performance: ~1-2 us @ 240 MHz (includes reservation)
- Pull-ups: Not enabled by this function (use PCR register)

#### Warning

- Floating inputs may read unpredictable values - use pull-up/pull-down
- Do not call from ISR (pin reservation may block)

#### Example:

```
// Configure button pin as input
rx_err_t err = gpio_set_input(RX_PORT_PIN(2, 0)); // Port 2, Pin 0
if (err != k_rx_ok) {
 rx_log_error("BTN", "Failed to configure button pin");
 return err;
}

// Read button state
bool pressed;
err = gpio_read(RX_PORT_PIN(2, 0), &pressed);
if (err == k_rx_ok && pressed) {
 rx_log_info("BTN", "Button pressed");
}
```

Here is the call graph for this function:

#### 8.1.5.20 gpio\_set\_output()

```
rx_err_t gpio_set_output (
 const rx_port_pin_t pin) [nodiscard]
```

Configure GPIO pin as digital output.

Configures the specified GPIO pin as a digital output with push-pull drive. Performs full hardware initialization including port direction register (PDR), port mode register (PMR), and open-drain control (ODR). Validates pin assignment and checks for peripheral conflicts.

## 8.1.5.21 Algorithm

1. Validate pin parameter (port exists, pin number valid)
2. Check pin is not already reserved by another peripheral
3. Unlock port write protection (PWPR register)
4. Set PMR bit to 0 (GPIO mode, not peripheral function)
5. Set PDR bit to 1 (output direction)
6. Ensure ODR is 0 (push-pull, not open-drain)
7. Lock port write protection
8. Mark pin as reserved in allocation tracker

## 8.1.5.22 Performance

- Cycles: ~120 @ 240 MHz
- Time: ~500 ns
- Stack: 8 bytes (pin validation, temporary registers)

## Parameters

|    |     |                                                                                                                                                                                                                                                                                                                       |
|----|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| in | pin | GPIO pin identifier from rx_port_constants.h <ul style="list-style-type: none"> <li>• Type: rx_port_pin_t (C23 typed enum)</li> <li>• Format: k_port_X_pin_Y (X = A-N, Y = 0-7)</li> <li>• Example: k_port_c_pin_0 (Port C, Pin 0)</li> <li>• Range: All valid combinations defined in rx_port_constants.h</li> </ul> |
|----|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Returns

rx\_err\_t Error code indicating success or failure

## Return values

|                            |                                                             |
|----------------------------|-------------------------------------------------------------|
| k_rx_ok                    | Pin successfully configured as output                       |
| k_rx_err_gpio_invalid_port | Port letter out of range (not A-N)                          |
| k_rx_err_gpio_invalid_pin  | Pin number out of range (not 0-7)                           |
| k_rx_err_gpio_conflict     | Pin already reserved by UART, SPI, I2C, or other peripheral |

## Precondition

Pin must not be currently in use by another peripheral

## Postcondition

Pin configured as push-pull output, initial state undefined (use `gpio_write_*` to set level)  
 Pin marked as reserved in internal allocation tracker

## Note

Thread Safety: NOT thread-safe. Do not call concurrently from multiple threads.  
 Initial State: Output level is undefined after configuration. Call [gpio\\_write\\_high\(\)](#) or [gpio\\_write\\_low\(\)](#) to set initial state.  
 Peripheral Conflicts: Automatically detects conflicts with UART, SPI, I2C pin assignments.

## Warning

Changing pin direction while peripheral is active may cause undefined behavior.

## Example: Motor Enable Pin

```
#include "hardware.h"

void motor_init(void) {
 // Configure motor enable pin as output
 rx_err_t err = gpio_set_output(k_port_c_pin_0);
 if (err != k_rx_ok) {
 rx_log_error_val("MOTOR", "Failed to configure enable pin", err);
 return;
 }

 // Set initial state (motors disabled)
 gpio_write_low(k_port_c_pin_0);
 rx_log_info("MOTOR", "Enable pin configured");
}
```

## Example: Multiple GPIO Outputs

```
void configure_leds(void) {
 const rx_port_pin_t led_pins[] = {
 k_port_e_pin_5, // LED1
 k_port_e_pin_6, // LED2
 k_port_e_pin_7, // LED3
 };

 for (uint8_t i = 0; i < 3; i++) {
 rx_err_t err = gpio_set_output(led_pins[i]);
 if (err != k_rx_ok) {
 rx_log_error_hex("GPIO", "LED init failed", i, 2);
 } else {
 gpio_write_low(led_pins[i]); // LEDs off initially
 }
 }
}
```

## Example: Error Handling

```
rx_err_t setup_motor_control_pins(void) {
 // Try to configure direction pin
 rx_err_t err = gpio_set_output(k_port_c_pin_1);
 if (err == k_rx_err_gpio_conflict) {
 rx_log_error("MOTOR", "Pin conflict - already used by SPI?");
 return err;
 } else if (err != k_rx_ok) {
 rx_log_error_val("MOTOR", "Unexpected error", err);
 return err;
 }

 return k_rx_ok;
}
```

See also

[gpio\\_set\\_input\(\)](#) Configure pin as digital input  
[gpio\\_write\\_high\(\)](#) Set output pin to logic high  
[gpio\\_write\\_low\(\)](#) Set output pin to logic low  
[gpio\\_toggle\(\)](#) Toggle output pin state  
[rx\\_port\\_constants.h](#) for complete pin definitions

Configures a GPIO pin for digital output mode. This function performs:

1. Parameter validation (port and pin number)
2. Pin reservation via the global pin validator (conflict detection)
3. PMR register clear (select GPIO mode instead of peripheral function)
4. PDR register set (configure as output direction)

#### 8.1.5.23 Register Operations

```
PMR &= ~(1 « pin) // Clear bit: Select GPIO mode (not peripheral)
PDR |= (1 « pin) // Set bit: Configure as output
```

#### 8.1.5.24 Pin Reservation

The function attempts to reserve the pin through `rx_infrastructure_get_pin_interface()`. If the pin is already reserved (`k_rx_err_gpio_conflict`), the function continues without error - this allows reconfiguration of already-owned pins.

#### 8.1.5.25 Initial Output State

This function does NOT set the initial output level. After calling [gpio\\_set\\_output\(\)](#), call [gpio\\_write\\_high\(\)](#) or [gpio\\_write\\_low\(\)](#) to set the desired level.

Precondition

Pin must be a valid GPIO-capable pin on RX72N  
 System infrastructure should be initialized (for pin validation)

Postcondition

Pin is configured as GPIO output  
 PMR bit for pin is cleared (GPIO mode)  
 PDR bit for pin is set (output direction)  
 Pin is reserved in validator (if available)

Note

Thread-safe: Pin reservation uses mutex, register writes are not atomic  
 Performance: ~1-2 us @ 240 MHz (includes reservation)  
 Idempotent: Safe to call multiple times on same pin

## Warning

Output level is undefined after this call - set with `gpio_write_*`  
 Do not call from ISR (pin reservation may block)

## Example:

```
// Configure LED pin as output
rx_err_t err = gpio_set_output(RX_PORT_PIN(0, 3)); // Port 0, Pin 3
if (err != k_rx_ok) {
 rx_log_error("LED", "Failed to configure LED pin");
 return err;
}

// Set initial state to low (LED off)
gpio_write_low(RX_PORT_PIN(0, 3));

// Toggle LED
gpio_toggle(RX_PORT_PIN(0, 3));
```

Here is the call graph for this function:

#### 8.1.5.26 gpio\_toggle()

```

rx_err_t gpio_toggle (
 const rx_port_pin_t pin) [nodiscard]

```

Toggle GPIO output pin state (high to low, or low to high).

Inverts the current output level of the specified GPIO pin by XOR-ing the corresponding bit in the Port Output Data Register (PODR). If the pin is currently high it becomes low, and vice versa. The pin must have been previously configured as output via [gpio\\_set\\_output\(\)](#).

## 8.1.5.27 Algorithm

1. Validate pin parameter (port exists, pin number valid)
2. Extract port letter and pin number from rx\_port\_pin\_t
3. XOR corresponding bit in PODR register (read-modify-write)

## Parameters

| in | pin | GPIO pin identifier from rx_port_constants.h                                                                                                                                                                                |
|----|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    |     | <ul style="list-style-type: none"> <li>• Type: rx_port_pin_t (C23 typed enum)</li> <li>• Format: k_port_X_pin_Y (X = A-N, Y = 0-7)</li> <li>• Must be configured as output via <a href="#">gpio_set_output()</a></li> </ul> |

## Returns

rx\_err\_t Error code indicating success or failure

## Return values

|                            |                                    |
|----------------------------|------------------------------------|
| k_rx_ok                    | Pin successfully toggled           |
| k_rx_err_gpio_invalid_port | Port letter out of range (not A-N) |
| k_rx_err_gpio_invalid_pin  | Pin number out of range (not 0-7)  |

## Precondition

Pin must be configured as output via [gpio\\_set\\_output\(\)](#)  
 Pin port and number must be within valid hardware range

## Postcondition

Pin output level is inverted from its previous state  
 PODR register bit for the pin is toggled

## Note

Thread Safety: NOT thread-safe. Concurrent toggles or writes to pins on the same port may cause read-modify-write races on the PODR register.

## Example: LED Heartbeat

```
// Toggle heartbeat LED every 500 ms
void heartbeat_task(void) {
 gpio_set_output(k_port_e_pin_5);
 while (1) {
 gpio_toggle(k_port_e_pin_5);
 tx_thread_sleep(50); // 500 ms at 100 Hz tick
 }
}
```

See also

[gpio\\_write\\_high\(\)](#) Set output pin to logic high  
[gpio\\_write\\_low\(\)](#) Set output pin to logic low  
[gpio\\_set\\_output\(\)](#) Configure pin as output first

Since

Version 1.0.0

Toggle GPIO output pin state (high to low, or low to high).

Inverts the current output state of a GPIO pin. If the pin is currently high, it becomes low. If currently low, it becomes high. Uses XOR operation for efficient toggling.

#### 8.1.5.28 Register Operation

```
PODR ^= (1 << pin) // XOR bit: Toggle output
```

#### 8.1.5.29 Atomicity Warning

This operation is a read-modify-write sequence and is NOT atomic. If an interrupt modifies the same port register between the read and write, the interrupt's change may be lost.

For thread-safe toggling, use explicit [write\\_high/write\\_low](#) with external synchronization, or disable interrupts around the toggle.

Precondition

Pin must be configured as output via [gpio\\_set\\_output\(\)](#)  
Port and pin numbers must be valid

Postcondition

PODR bit for pin is inverted  
Pin output level is opposite of previous state

Note

NOT thread-safe: Read-modify-write operation  
NOT atomic: Can race with ISRs on same port  
Performance: ~150 ns @ 240 MHz

Warning

Race condition possible with ISRs modifying same port  
Use [gpio\\_write\\_high/low](#) with sync for critical applications

Example:

```
// Blink LED in loop
while (running) {
 gpio_toggle(RX_PORT_PIN(0, 3)); // Toggle LED
 tx_thread_sleep(50); // 50ms delay (20 Hz blink)
}
```

00719 const uint8_t pin_mask = (uint8_t)(k_gpio_bit_set « pin_num);
00720 port_base->podr ^= pin_mask;
00721
00722 return k_rx_ok;
00723 }
```

References [internal\\_validate\\_port\\_pin\(\)](#), [k\\_gpio\\_bit\\_set](#), [rx\\_port\\_regs\\_t::podr](#), [rx\\_port\\_get\\_base\(\)](#), and [s\\_tag](#).

Here is the call graph for this function:

#### 8.1.5.30 gpio\_write\_high()

```
rx_err_t gpio_write_high (
 const rx_port_pin_t pin) [nodiscard]
```

Set GPIO output pin to logic high (VDD).

Drives the specified GPIO pin to logic high by setting the corresponding bit in the Port Output Data Register (PODR). The pin must have been previously configured as output via [gpio\\_set\\_output\(\)](#). Writing to an input pin has no effect on the physical pin state.

## 8.1.5.31 Algorithm

1. Validate pin parameter (port exists, pin number valid)
2. Extract port letter and pin number from rx\_port\_pin\_t
3. Set corresponding bit in PODR register (atomic read-modify-write)

## Parameters

| in | pin | GPIO pin identifier from rx_port_constants.h                                                                                                                                                                                |
|----|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    |     | <ul style="list-style-type: none"> <li>• Type: rx_port_pin_t (C23 typed enum)</li> <li>• Format: k_port_X_pin_Y (X = A-N, Y = 0-7)</li> <li>• Must be configured as output via <a href="#">gpio_set_output()</a></li> </ul> |

## Returns

rx\_err\_t Error code indicating success or failure

## Return values

|                            |                                    |
|----------------------------|------------------------------------|
| k_rx_ok                    | Pin successfully driven high       |
| k_rx_err_gpio_invalid_port | Port letter out of range (not A-N) |
| k_rx_err_gpio_invalid_pin  | Pin number out of range (not 0-7)  |

## Precondition

Pin must be configured as output via [gpio\\_set\\_output\(\)](#)  
 Pin port and number must be within valid hardware range

## Postcondition

Pin output level is logic high (VDD, typically 3.3V)  
 PODR register bit for the pin is set to 1

## Note

Thread Safety: NOT thread-safe. Concurrent writes to pins on the same port may cause read-modify-write races on the PODR register.

## Example: Enable Motor

```
// Enable motor driver (active high)
rx_err_t err = gpio_write_high(k_port_c_pin_0);
if (err != k_rx_ok) {
 rx_log_error_val("MOTOR", "Failed to enable motor", err);
}
```

See also

[gpio\\_write\\_low\(\)](#) Set output pin to logic low  
[gpio\\_toggle\(\)](#) Toggle output pin state  
[gpio\\_set\\_output\(\)](#) Configure pin as output first

Since

Version 1.0.0

Set GPIO output pin to logic high (VDD).

Sets a GPIO output pin to logic high level. On the RX72N, this means the pin outputs VCC (typically 3.3V). The pin must be configured as an output before calling this function.

#### 8.1.5.32 Register Operation

```
PODR |= (1 « pin) // Set bit: Output high
```

#### 8.1.5.33 Timing

The output level changes on the next peripheral clock cycle after the register write completes. GPIO toggle rate is limited by bus speed.

Precondition

Pin must be configured as output via [gpio\\_set\\_output\(\)](#)  
Port and pin numbers must be valid

Postcondition

PODR bit for pin is set (output high)  
Pin outputs VCC level (typically 3.3V)

Note

NOT thread-safe: Direct register write without synchronization  
Performance: ~100 ns @ 240 MHz  
ISR-safe: Can be called from interrupt handlers

Warning

No check that pin is configured as output  
Calling on input pin has no visible effect

Example:

```
// Turn on LED (active high)
rx_err_t err = gpio_write_high(RX_PORT_PIN(0, 3));
if (err != k_rx_ok) {
 // Handle error
}
```

Here is the call graph for this function:

#### 8.1.5.34 gpio\_write\_low()

```
rx_err_t gpio_write_low (
 const rx_port_pin_t pin) [nodiscard]
```

Set GPIO output pin to logic low (GND).

Drives the specified GPIO pin to logic low by clearing the corresponding bit in the Port Output Data Register (PODR). The pin must have been previously configured as output via [gpio\\_set\\_output\(\)](#). Writing to an input pin has no effect on the physical pin state.

#### 8.1.5.35 Algorithm

1. Validate pin parameter (port exists, pin number valid)

2. Extract port letter and pin number from rx\_port\_pin\_t
3. Clear corresponding bit in PODR register (atomic read-modify-write)

## Parameters

|    |     |                                                                                                                                                                                                                                                                          |
|----|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| in | pin | GPIO pin identifier from rx_port_constants.h <ul style="list-style-type: none"> <li>• Type: rx_port_pin_t (C23 typed enum)</li> <li>• Format: k_port_X_pin_Y (X = A-N, Y = 0-7)</li> <li>• Must be configured as output via <a href="#">gpio_set_output()</a></li> </ul> |
|----|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Returns

rx\_err\_t Error code indicating success or failure

## Return values

|                            |                                    |
|----------------------------|------------------------------------|
| k_rx_ok                    | Pin successfully driven low        |
| k_rx_err_gpio_invalid_port | Port letter out of range (not A-N) |
| k_rx_err_gpio_invalid_pin  | Pin number out of range (not 0-7)  |

## Precondition

Pin must be configured as output via [gpio\\_set\\_output\(\)](#)  
Pin port and number must be within valid hardware range

## Postcondition

Pin output level is logic low (GND, 0V)  
PODR register bit for the pin is cleared to 0

## Note

Thread Safety: NOT thread-safe. Concurrent writes to pins on the same port may cause read-modify-write races on the PODR register.

## Example: Disable Motor

```
// Disable motor driver (active high enable)
rx_err_t err = gpio_write_low(k_port_c_pin_0);
if (err != k_rx_ok) {
 rx_log_error_val("MOTOR", "Failed to disable motor", err);
}
```

## See also

[gpio\\_write\\_high\(\)](#) Set output pin to logic high  
[gpio\\_toggle\(\)](#) Toggle output pin state  
[gpio\\_set\\_output\(\)](#) Configure pin as output first

Since

Version 1.0.0

Set GPIO output pin to logic low (GND).

Sets a GPIO output pin to logic low level. On the RX72N, this means the pin outputs GND (0V). The pin must be configured as an output before calling this function.

#### 8.1.5.36 Register Operation

```
PODR &= ~(1 « pin) // Clear bit: Output low
```

#### 8.1.5.37 Open-Drain Mode

If the pin is configured for open-drain mode (ODR register), setting low actively pulls the pin to GND. Setting high makes the pin float (high-impedance), requiring an external pull-up.

Precondition

Pin must be configured as output via [gpio\\_set\\_output\(\)](#)

Port and pin numbers must be valid

Postcondition

PODR bit for pin is cleared (output low)

Pin outputs GND level (0V)

Note

NOT thread-safe: Direct register write without synchronization

Performance: ~100 ns @ 240 MHz

ISR-safe: Can be called from interrupt handlers

Warning

No check that pin is configured as output

Calling on input pin has no visible effect

Example:

```
// Turn off LED (active high)
rx_err_t err = gpio_write_low(RX_PORT_PIN(0, 3));
if (err != k_rx_ok) {
 // Handle error
}
```

Here is the call graph for this function:

#### 8.1.5.38 riic\_deinit\_peripheral()

```

rx_err_t riic_deinit_peripheral (
 const riic_channel_t channel) [nodiscard]

```

Deinitialize an RIIC channel previously initialized in peripheral mode.

Disables peripheral address match (ICSER.SAR0E), clears SARL0/SARU0 address registers, and resets the RIIC module. After this call, the channel may be reinitialized via [riic\\_init\(\)](#) or [riic\\_init\\_peripheral\(\)](#).

##### Parameters

|    |         |                                                         |
|----|---------|---------------------------------------------------------|
| in | channel | RIIC channel to deinitialize (channel.value range: 0-2) |
|----|---------|---------------------------------------------------------|

## Returns

rx\_err\_t Error code

## Return values

|                        |                                                |
|------------------------|------------------------------------------------|
| k_rx_ok                | Channel deinitialized successfully             |
| k_rx_err_invalid_arg   | channel.value >= k_riic_max_channels           |
| k_rx_err_invalid_state | Channel was not initialized in peripheral mode |

## Precondition

channel.value must be in range [0, k\_riic\_max\_channels - 1]

Channel must have been initialized via [riic\\_init\\_peripheral\(\)](#)

## Postcondition

Channel mode reset to uninitialized; safe to call [riic\\_init\\_peripheral\(\)](#) again

Peripheral address match disabled on the hardware

## Note

Only available on RX72N target (guarded by RX preprocessor)

Not thread-safe; provide external synchronization if needed

## Example:

```
riic_channel_t ch = { .value = k_i2c_comm_default_channel };
rx_err_t err = riic_deinit_peripheral(ch);
if (err != k_rx_ok) {
 // Channel was not in peripheral mode or index out of range
 return err;
}
// Channel is now free; may be reinitialized for controller or peripheral use
```

## See also

[riic\\_init\\_peripheral\(\)](#) Complementary initialization function

## Since

Version 1.0.0

Deinitialize an RIIC channel previously initialized in peripheral mode.

Disables the peripheral address match (ICSER.SAR0E), clears the SARL0/SARU0 address registers, resets the RIIC module, and marks the channel as uninitialized. After this call, [riic\\_init\(\)](#) or [riic\\_init\\_peripheral\(\)](#) may be called again on the same channel.

## Precondition

channel.value must be in range [0, k\_riic\_max\_channels - 1]  
 Channel must have been initialized via [riic\\_init\\_peripheral\(\)](#)

## Postcondition

s\_riic\_channel\_mode[channel.value] == k\_riic\_mode\_uninitialized on success  
 RIIC peripheral address match disabled; hardware in reset state

## Note

Only available on RX72N target (guarded by RX preprocessor)  
 Not thread-safe; provide external synchronization if needed

#### 8.1.5.39 riic\_init()

```

rx_err_t riic_init (
 riic_channel_t channel,
 uint32_t frequency_hz) [nodiscard]

```

Initialize RIIC channel for I2C controller communication.

Configures the specified RIIC peripheral channel for I2C controller mode at the requested clock frequency. Performs full hardware initialization including module stop release, pin function selection (SCL/SDA via MPC), internal reset sequence, bit rate register (BRH/BRL) calculation from PCLKB, and interrupt configuration.

#### 8.1.5.40 Algorithm

1. Validate channel number (0-2) and frequency
2. Release RIIC module from module stop (MSTPCRB)
3. Assert internal reset (ICCR1.IICRST = 1)
4. Configure SCL/SDA pins via MPC register
5. Set bit rate registers (BRH/BRL) from PCLKB and frequency\_hz
6. Configure noise filter, timeout detection
7. Release internal reset (ICCR1.IICRST = 0)
8. Enable I2C bus (ICCR1.ICE = 1)

#### 8.1.5.41 Supported Frequencies

| Frequency  | Mode      | BRL/BRH         | Max Bus Length |
|------------|-----------|-----------------|----------------|
| 100000 Hz  | Standard  | Auto-calculated | 1 m            |
| 400000 Hz  | Fast      | Auto-calculated | 0.3 m          |
| 1000000 Hz | Fast-plus | Auto-calculated | 0.1 m          |

## Parameters

|    |              |                                                                                                                                                                  |
|----|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| in | channel      | RIIC channel wrapper <ul style="list-style-type: none"><li>channel.value range: 0-2</li><li>Use <code>{.value = N}</code> designated initializer</li></ul>       |
| in | frequency_hz | I2C clock frequency in Hz <ul style="list-style-type: none"><li>Valid values: 100000, 400000, 1000000</li><li>Must match connected device capabilities</li></ul> |

## Returns

`rx_err_t` Error code indicating success or failure

## Return values

|                                     |                                      |
|-------------------------------------|--------------------------------------|
| <code>k_rx_ok</code>                | Channel successfully initialized     |
| <code>k_rx_err_invalid_arg</code>   | Channel > 2 or unsupported frequency |
| <code>k_rx_err_invalid_state</code> | Channel already initialized          |

## Precondition

Channel must not be already initialized (call `riic deinit` first to reinitialize)  
System clocks must be configured (PCLKB running at expected frequency)

## Postcondition

RIIC channel configured and ready for I2C transactions  
SCL/SDA pins configured with open-drain output and internal pull-ups

## Note

Thread Safety: NOT thread-safe. Initialize each channel from a single thread during system startup.

## Example: Initialize IMU I2C Bus

```
riic_channel_t ch = {.value = 0};
rx_err_t err = riic_init(ch, 400000); // 400 kHz fast mode
if (err != k_rx_ok) {
 rx_log_error_val("I2C", "RIIC0 init failed", err);
 return;
}
rx_log_info("I2C", "RIIC0 initialized at 400 kHz");
```

Here is the call graph for this function:

#### 8.1.5.42 riic\_init\_peripheral()

```

rx_err_t riic_init_peripheral (
 const riic_channel_t channel,
 const i2c_device_addr_t device_addr) [nodiscard]

```

Initialize RIIC channel in peripheral (device) mode.

Configures the RIIC peripheral to act as an I2C peripheral device, responding to a fixed 7-bit I2C address issued by a controller (RPi5). Sets up the peripheral address register (SARL0/SARU0), enables address match detection (ICSER.SAR0E), and leaves the module in peripheral mode (MS=0 in ICMR1).

Peripheral Mode Architecture:

- RPi5 acts as I2C controller (generates SCL, START, STOP)
- RX72N acts as I2C peripheral (responds to address, provides/accepts data)
- Address matching handled in hardware (ICSER.SAR0E)
- Data transfer polled via ICSR2.RDRF and ICSR2.TDRE

#### Parameters

|    |             |                                                 |
|----|-------------|-------------------------------------------------|
| in | channel     | RIIC channel wrapper (channel.value range: 0-2) |
| in | device_addr | 7-bit peripheral address for this device        |

## Returns

`rx_err_t` Error code

## Return values

|                                     |                                                                 |
|-------------------------------------|-----------------------------------------------------------------|
| <code>k_rx_ok</code>                | Channel initialized in peripheral mode                          |
| <code>k_rx_err_invalid_arg</code>   | Channel value out of range                                      |
| <code>k_rx_err_invalid_state</code> | Channel already initialized; deinitialize before reinitializing |

## Precondition

`channel.value` must be in range `[0, 2]` (i.e., `< k_riic_max_channels`)

`device_addr.value` must be in range `[0x08, 0x77]` (valid non-reserved 7-bit I2C address)

## Postcondition

RIIC peripheral responds to `device_addr` on the I2C bus

`s_riic_channel_initialized[channel.value] == true` on success

## Note

Only available on RX72N target (guarded by RX preprocessor)

Not thread-safe during initialization

## See also

[riic\\_peripheral\\_read\(\)](#) Read data written by I2C controller

## Since

Version 1.0.0

Configures the RIIC peripheral to act as an I2C peripheral device, responding to a fixed 7-bit I2C address issued by a controller (RPI5). Sets up the peripheral address register (SARL0/SARU0), enables address match detection (ICSER.SAR0E), and leaves the module in peripheral mode (MS=0 in ICMR1).

## 8.1.5.43 Initialization Sequence

1. Validate channel number and device address
2. Enable RIIC module clock (clear MSTPCRB bit)
3. Reset RIIC internal state (IICRST)
4. Configure peripheral address in SARL0/SARU0
5. Enable SAR0 address match detection (ICSER.SAR0E)
6. Configure peripheral mode (MS=0), 7-bit addressing
7. Enable I2C bus interface (ICE)
8. Mark channel as initialized

## Precondition

channel.value must be in range [0, k\_riic\_max\_channels - 1]  
 device\_addr.value must be <= k\_riic\_addr\_max\_7bit (0x7F)

## Postcondition

RIIC peripheral responds to device\_addr on the I2C bus  
 s\_riic\_channel\_mode[channel.value] == k\_riic\_mode\_peripheral

## Note

Only available on RX72N target (guarded by RX preprocessor)  
 Not thread-safe during initialization

#### 8.1.5.44 riic\_peripheral\_read()

```

rx_err_t riic_peripheral_read (
 const riic_channel_t channel,
 uint8_t * data,
 const uint16_t max_length,
 uint16_t * bytes_read) [nodiscard]

```

Read bytes written by the I2C controller to this peripheral.

Polls ICSR2.RDRF (Receive Data Register Full) to detect incoming bytes from the I2C controller (RPI5). Reads up to `max_length` bytes. Returns immediately with `bytes_read=0` if no data is currently available.

##### Parameters

|     |            |                                                 |
|-----|------------|-------------------------------------------------|
| in  | channel    | RIIC channel wrapper (channel.value range: 0-2) |
| out | data       | Buffer to store received bytes                  |
| in  | max_length | Maximum number of bytes to read                 |
| out | bytes_read | Actual number of bytes read (may be 0)          |

## Returns

`rx_err_t` Error code

## Return values

|                                     |                                                                                                                             |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>k_rx_ok</code>                | Read completed (check <code>bytes_read</code> for count)                                                                    |
| <code>k_rx_err_null_ptr</code>      | <code>data</code> or <code>bytes_read</code> is <code>nullptr</code>                                                        |
| <code>k_rx_err_invalid_arg</code>   | Channel value out of range or <code>max_length == 0</code> or <code>max_length &gt; k_riic_peripheral_transfer_limit</code> |
| <code>k_rx_err_invalid_state</code> | Channel not initialized via <a href="#">riic_init_peripheral()</a>                                                          |

## Precondition

channel must be initialized via [riic\\_init\\_peripheral\(\)](#)

`data != nullptr` with capacity for at least `max_length` bytes

`max_length >= 1 && max_length <= k_riic_peripheral_transfer_limit`

## Postcondition

`*bytes_read` contains number of bytes placed in `data` (0 to `max_length`)

`data[0..*bytes_read-1]` contain valid received bytes on `k_rx_ok`

## Note

Non-blocking: returns immediately with available data

Only available on RX72N target (guarded by RX preprocessor)

## See also

[riic\\_init\\_peripheral\(\)](#) Initialize channel first

[riic\\_peripheral\\_write\(\)](#) Provide read data to controller

## Since

Version 1.0.0

Polls ICSR2.RDRF (Receive Data Register Full) to detect incoming bytes from the I2C controller (RPi5). Reads up to `max_length` bytes into the caller-supplied buffer. Returns immediately with `bytes_read == 0` if no data is currently available (non-blocking). Each byte read clears the RDRF flag automatically on the RX72N.

## 8.1.5.45 Read Algorithm

1. Validate pointers, channel, and max\_length
2. Clear \*bytes\_read to 0
3. Poll ICSR2.RDRF; if set, read ICDRR into data[\*bytes\_read], increment count
4. Repeat until RDRF clear or max\_length reached
5. Return k\_rx\_ok with actual count in \*bytes\_read

## Precondition

channel must be initialized via [riic\\_init\\_peripheral\(\)](#)  
 data != nullptr with at least max\_length bytes of capacity  
 max\_length >= 1 && max\_length <= k\_riic\_peripheral\_transfer\_limit

## Postcondition

\*bytes\_read contains the number of bytes placed in data (0 to max\_length)  
 data[0..(\*bytes\_read)-1] contain valid received bytes on k\_rx\_ok

## Note

Non-blocking: returns immediately with available data (bytes\_read may be 0)  
 Only available on RX72N target (guarded by RX preprocessor)  
 Not thread-safe, caller must provide external synchronization

#### 8.1.5.46 riic\_peripheral\_write()

```

rx_err_t riic_peripheral_write (
 const riic_channel_t channel,
 const uint8_t * data,
 const uint16_t length) [nodiscard]

```

Write bytes for the I2C controller to read from this peripheral.

Polls ICSR2.TDRE (Transmit Data Register Empty) to detect when the I2C controller is reading from this peripheral. Writes up to length bytes into the ICDRT transmit data register. Returns immediately if the transmit register is not yet empty (controller not currently reading).

#### Parameters

|    |         |                                                                             |
|----|---------|-----------------------------------------------------------------------------|
| in | channel | RIIC channel wrapper (channel.value range: 0-2)                             |
| in | data    | Pointer to data buffer to write                                             |
| in | length  | Number of bytes to write (valid range: 1..k_riic_peripheral_transfer_limit) |

## Returns

`rx_err_t` Error code

## Return values

|                                     |                                                                                                    |
|-------------------------------------|----------------------------------------------------------------------------------------------------|
| <code>k_rx_ok</code>                | Write completed                                                                                    |
| <code>k_rx_err_null_ptr</code>      | data is nullptr                                                                                    |

## Precondition

channel must be initialized via [riic\\_init\\_peripheral\(\)](#)

data != nullptr with at least length valid bytes

length >= 1 && length <= `k_riic_peripheral_transfer_limit`

## Postcondition

On `k_rx_ok`: all length bytes have been written to ICDRT

On `k_rx_err_timeout`: partial write may have occurred

## Note

Only available on RX72N target (guarded by RX preprocessor)

Not thread-safe, caller must provide external synchronization

## See also

[riic\\_init\\_peripheral\(\)](#) Initialize channel first

[riic\\_peripheral\\_read\(\)](#) Receive data from controller

## Since

Version 1.0.0

Loads data bytes into the RIIC transmit data register (ICDRT) one at a time. For each byte, polls ICSR2.TDRE (Transmit Data Register Empty) until the register is available or a 1 ms timeout expires, then writes the byte. The controller clock-shifts bytes out automatically after each write.

## 8.1.5.47 Write Algorithm

1. Validate pointer, channel, and length
2. For each byte in data[0..length-1]: a. Poll ICSR2.TDRE with k\_riic\_periph\_timeout\_us count-down b. If timeout, return k\_rx\_err\_timeout c. Write data[i] to ICDRT
3. Return k\_rx\_ok

## Precondition

channel must be initialized via [riic\\_init\\_peripheral\(\)](#)  
 data != nullptr with at least length valid bytes  
 length >= 1

## Postcondition

On k\_rx\_ok: all length bytes have been written to ICDRT  
 On k\_rx\_err\_timeout: partial write may have occurred (i bytes written)

## Note

Only available on RX72N target (guarded by RX preprocessor)  
 Not thread-safe, caller must provide external synchronization

Here is the call graph for this function:

#### 8.1.5.48 riic\_read()

```

rx_err_t riic_read (
 const riic_channel_t channel,
 const i2c_device_addr_t device_addr,
 uint8_t * data,
 const uint16_t length) [nodiscard]

```

Read data from I2C device on specified RIIC channel.

Performs a complete I2C read transaction: generates START condition, transmits device address with read bit (R/W=1), receives data bytes with ACK (NACK on last byte), and generates STOP condition. The function blocks until all bytes are received or an error occurs.

#### 8.1.5.49 Transaction Sequence

1. Generate START condition
2. Send device address byte (7-bit address << 1 | 1)
3. Wait for ACK from peripheral
4. Receive data bytes, sending ACK after each (NACK after last byte)
5. Generate STOP condition

6. Wait for bus idle (BBSY = 0)

#### Parameters

|     |                  |                                                                                                                                                                                                           |

#### Returns

rx\_err\_t Error code indicating success or failure

#### Return values

|                        |                                                            |
|------------------------|------------------------------------------------------------|
| k_rx_ok                | All bytes successfully received                            |
| k_rx_err_null_ptr      | data pointer is nullptr                                    |
| k_rx_err_invalid_state | Channel not initialized via <a href="#">riic_init()</a>    |
| k_rx_err_timeout       | Bus timeout waiting for data or bus idle                   |
| k_rx_err_nack          | Device sent NACK on address (wrong address or device busy) |

#### Precondition

Channel must be initialized via [riic\\_init\(\)](#)

data pointer must be valid with space for at least length bytes

#### Postcondition

data buffer contains received bytes if function succeeds

I2C bus returned to idle state (STOP condition generated)

#### Note

Thread Safety: NOT thread-safe. Do not perform concurrent transactions on the same RIIC channel. Different channels may be used from different threads.

## Example: Read IMU Accelerometer Data

```

riic_channel_t ch = {.value = 0};
i2c_device_addr_t imu_addr = {.value = 0x68};

uint8_t accel_data[6];
rx_err_t err = riic_read(ch, imu_addr, accel_data, 6);
if (err != k_rx_ok) {
 rx_log_error_val("IMU", "Failed to read accel data", err);
}

```

See also

[riic\\_write\(\)](#) Write data to I2C device  
[riic\\_write\\_read\(\)](#) Combined write-then-read (register read pattern)  
[riic\\_init\(\)](#) Initialize RIIC channel first

Since

Version 1.0.0

Read data from I2C device on specified RIIC channel.

Performs a complete I2C read transaction: START, address+R, receive data bytes (ACK all except last), NACK last byte, STOP. This function is suitable for reading device status, sensor data, or sequential memory reads where the device auto-increments its internal pointer.

## 8.1.5.50 Transaction Sequence

8.1.5.51 When to Use `riic_read()` vs `riic_write_read()`

| Function                          | Use When                                          |
|-----------------------------------|---------------------------------------------------|
| <a href="#">riic_read()</a>       | Device auto-increments address, or reading status |
| <a href="#">riic_write_read()</a> | Need to specify register address first            |

## 8.1.5.52 Common Use Cases

- Read device status register (if device supports direct read)
- Continue reading after previous write set address pointer
- Read from devices with auto-increment address mode

## Precondition

[riic\\_init\(\)](#) called for this channel  
 data != nullptr  
 Buffer size >= length  
 length >= 1 && length <= 256  
 device\_addr.value <= 127

## Postcondition

On success: data contains received bytes, bus released  
 On failure: Bus released via STOP

## Note

This is a blocking function - returns only after transfer complete.  
 NACK is automatically sent before reading last byte.

## Warning

Most peripherals require [riic\\_write\\_read\(\)](#) to specify which register to read from. Use this function only when the device supports direct reads or address auto-increment.

## Example: Read Temperature Sensor (Direct Read)

```

// Read 2 bytes from temperature sensor at address 0x48
// (sensor auto-reports temperature on read)
uint8_t temp_data[2];
riic_channel_t channel = {.value = 0};
i2c_device_addr_t addr = {.value = 0x48};

rx_err_t err = riic_read(channel, addr, temp_data, 2);
if (err == k_rx_ok) {
 int16_t raw = (temp_data[0] « 8) | temp_data[1];
 float celsius = raw * 0.0625f;
}

```

Here is the call graph for this function:

### 8.1.5.53 riic\_write()

```

rx_err_t riic_write (
 const riic_channel_t channel,
 const i2c_device_addr_t device_addr,
 const uint8_t * data,
 const uint16_t length) [nodiscard]

```

Write data to I2C device on specified RIIC channel.

Performs a complete I2C write transaction: generates START condition, transmits device address with write bit (R/W=0), sends data bytes, and generates STOP condition. Each byte is acknowledged by the peripheral device. The function blocks until all bytes are transmitted or an error occurs.

### 8.1.5.54 Transaction Sequence

1. Generate START condition
2. Send device address byte (7-bit address << 1 | 0)
3. Wait for ACK from peripheral
4. Send data bytes one at a time, waiting for ACK after each

5. Generate STOP condition
6. Wait for bus idle (BBSY = 0)

#### Parameters

|    |                  |                                                                                                                                                |
|----|------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| in | channel          | RIIC channel wrapper <ul style="list-style-type: none"><li>channel.value range: 0-2</li></ul>                                                  |
| in | device_↵<br>addr | 7-bit I2C device address wrapper <ul style="list-style-type: none"><li>device_addr.value range: 0x08-0x77</li></ul>                            |
| in | data             | Pointer to data buffer to write <ul style="list-style-type: none"><li>Must not be nullptr</li><li>Must contain at least length bytes</li></ul> |
| in | length           | Number of bytes to write <ul style="list-style-type: none"><li>Range: 1-65535</li></ul>                                                        |

#### Returns

rx\_err\_t Error code indicating success or failure

#### Return values

|                        |                                                         |
|------------------------|---------------------------------------------------------|
| k_rx_ok                | All bytes successfully written and ACKed                |
| k_rx_err_null_ptr      | data pointer is nullptr                                 |
| k_rx_err_invalid_state | Channel not initialized via <a href="#">riic_init()</a> |
| k_rx_err_timeout       | Bus timeout waiting for ACK or bus idle                 |
| k_rx_err_nack          | Device sent NACK (wrong address or device busy)         |

#### Precondition

Channel must be initialized via [riic\\_init\(\)](#)

data pointer must be valid and contain at least length bytes

#### Postcondition

All data bytes transmitted to the I2C device if successful

I2C bus returned to idle state (STOP condition generated)

#### Note

Thread Safety: NOT thread-safe. Do not perform concurrent transactions on the same RIIC channel. Different channels may be used from different threads.

## Example: Write IMU Configuration Register

```

riic_channel_t ch = {.value = 0};
i2c_device_addr_t imu_addr = {.value = 0x68};

// Write power management register (0x6B) to wake up MPU6050
uint8_t wake_cmd[] = {0x6B, 0x00};
rx_err_t err = riic_write(ch, imu_addr, wake_cmd, 2);
if (err != k_rx_ok) {
 rx_log_error_val("IMU", "Failed to wake IMU", err);
}

```

[riic\\_init\(\)](#) Initialize RIIC channel first

Since

Version 1.0.0

Write data to I2C device on specified RIIC channel.

Performs a complete I2C write transaction: START, address+W, data bytes, STOP. This function is suitable for writing configuration registers, sending commands, or storing data in EEPROM.

## 8.1.5.55 Transaction Sequence

## 8.1.5.56 Common Use Cases

| Use Case              | Data Format                 |
|-----------------------|-----------------------------|
| Config register write | [reg_addr, value]           |
| Multi-byte register   | [reg_addr, val0, val1, ...] |
| EEPROM page write     | [addr_hi, addr_lo, data...] |
| Sensor command        | [command_↵ byte]            |

## 8.1.5.57 Error Handling

On any error (timeout or NACK), the function issues a STOP condition to release the bus before returning. The original error code is preserved.

## Precondition

`riic_init()` called for this channel  
`data != nullptr`  
`length >= 1 && length <= 256`  
`device__addr.value <= 127`

## Postcondition

On success: All bytes transferred, bus released  
 On failure: Bus released via STOP

## Note

This is a blocking function - returns only after transfer complete.  
 STOP is always issued (success or failure) to release the bus.

## Warning

NACK on address usually means device not present or wrong address.  
 NACK on data may indicate device buffer full or write-protected.

## Example: Write Configuration Register

```
// Write value 0x42 to register 0x05 of device at address 0x48
uint8_t config_data[2] = {0x05, 0x42}; // [reg_addr, value]
riic_channel_t channel = {.value = 0};
i2c_device_addr_t addr = {.value = 0x48};

rx_err_t err = riic_write(channel, addr, config_data, 2);
if (err != k_rx_ok) {
 handle_i2c_error(err);
}
```

Here is the call graph for this function:

#### 8.1.5.58 riic\_write\_read()

```

rx_err_t riic_write_read (
 const riic_channel_t channel,
 const i2c_device_addr_t device_addr,
 const uint8_t * write_data,
 const uint16_t write_length,
 uint8_t * read_data,
 const uint16_t read_length) [nodiscard]

```

Write then read from I2C device using repeated START (combined transaction).

Performs an I2C combined write-then-read transaction using a repeated START condition. This is the standard pattern for reading device registers: write the register address, then issue a repeated START and read back the register data without releasing the bus between operations.

#### 8.1.5.59 Transaction Sequence

1. Generate START condition
2. Send device address byte (7-bit address << 1 | 0) – write mode
3. Wait for ACK from peripheral
4. Send write\_data bytes (typically register address), ACK after each
5. Generate repeated START condition (no STOP)
6. Send device address byte (7-bit address << 1 | 1) – read mode
7. Wait for ACK from peripheral
8. Receive read\_data bytes, ACK each (NACK on last byte)
9. Generate STOP condition
10. Wait for bus idle (BBSY = 0)

## Parameters

|     |              |                                                                                                                                                                                                                |

## Returns

rx\_err\_t Error code indicating success or failure

## Return values

|                        |                                                         |
|------------------------|---------------------------------------------------------|
| k_rx_ok                | Write and read completed successfully                   |
| k_rx_err_null_ptr      | write_data or read_data pointer is nullptr              |
| k_rx_err_invalid_state | Channel not initialized via <a href="#">riic_init()</a> |
| k_rx_err_timeout       | Bus timeout during write or read phase                  |
| k_rx_err_nack          | Device sent NACK (wrong address or device busy)         |

## Precondition

Channel must be initialized via [riic\\_init\(\)](#)

write\_data and read\_data pointers must be valid with sufficient size

## Postcondition

read\_data buffer contains received register data if function succeeds

I2C bus returned to idle state (STOP condition generated)

## Note

Thread Safety: NOT thread-safe. Do not perform concurrent transactions on the same RIIC channel. Different channels may be used from different threads.

Example: Read IMU WHO\_AM\_I Register

```
riic_channel_t ch = {.value = 0};
i2c_device_addr_t imu_addr = {.value = 0x68};

uint8_t reg_addr = 0x75; // WHO_AM_I register
uint8_t who_am_i;
rx_err_t err = riic_write_read(ch, imu_addr, ®_addr, 1, &who_am_i, 1);
if (err == k_rx_ok && who_am_i == 0x68) {
 rx_log_info("IMU", "MPU6050 detected");
}
```

[riic\\_read\(\)](#) Read-only transaction  
[riic\\_init\(\)](#) Initialize RIIC channel first

Since

Version 1.0.0

Write then read from I2C device using repeated START (combined transaction).

Performs a complete I2C write-read transaction using a repeated START condition. This is the most common pattern for reading registers from I2C peripherals: write the register address, then read the data.

#### 8.1.5.60 Transaction Sequence (Register Read)

#### 8.1.5.61 Why Repeated START?

The repeated START (Sr) is critical for atomic register access:

| Approach     | Bus Release | Risk                               |
|--------------|-------------|------------------------------------|
| STOP + START | Yes         | Another controller could interrupt |

| Approach       | Bus Release | Risk                  |
|----------------|-------------|-----------------------|
| Repeated START | No          | Transaction is atomic |

Many I2C peripherals require repeated START and may not work correctly with separate write-then-read transactions.

#### 8.1.5.62 Common Use Cases

| Peripheral Type | write_data            | read_length | Purpose            |
|-----------------|-----------------------|-------------|--------------------|
| Temperature     | [reg_↵<br>addr]       | 2           | Read temp register |
| EEPROM          | [addr_hi,<br>addr_lo] | N           | Read N bytes       |
| Accelerometer   | [reg_↵<br>addr]       | 6           | Read XYZ axes      |
| RTC             | [seconds_↵<br>reg]    | 7           | Read time          |

#### Precondition

```

riic_init() called for this channel
write_data != nullptr
read_data != nullptr
write_length >= 1 && write_length <= 256
read_length >= 1 && read_length <= 256
device_addr.value <= 127

```

#### Postcondition

On success: read\_data contains register contents, bus released  
On failure: Bus released via STOP

#### Note

This is a blocking function - returns only after transfer complete.  
Uses repeated START (no bus release between write and read phases).  
NACK is automatically sent before reading last byte.

#### Example: Read WHO\_AM\_I Register from IMU

```

// Read WHO_AM_I register (0x0F) from MPU6050 at address 0x68
riic_channel_t channel = {.value = 0};
i2c_device_addr_t imu_addr = {.value = 0x68};

uint8_t reg_addr = 0x0F; // WHO_AM_I register
uint8_t who_am_i;

rx_err_t err = riic_write_read(channel, imu_addr,
 ®_addr, 1, // Write: register address
 &who_am_i, 1); // Read: 1 byte

if (err == k_rx_ok && who_am_i == 0x68) {
 // IMU detected and responding correctly
}

```

Example: Read 6 Bytes of Accelerometer Data

```
// Read ACCEL_XOUT_H through ACCEL_ZOUT_L (6 bytes starting at 0x3B)
uint8_t reg_addr = 0x3B;
uint8_t accel_data[6];

rx_err_t err = riic_write_read(channel, imu_addr,
 ®_addr, 1,
 accel_data, 6);

if (err == k_rx_ok) {
 int16_t accel_x = (accel_data[0] « 8) | accel_data[1];
 int16_t accel_y = (accel_data[2] « 8) | accel_data[3];
 int16_t accel_z = (accel_data[4] « 8) | accel_data[5];
}
```

#### 8.1.5.63 `rspi_controller_deinit()`

```

rx_err_t rspi_controller_deinit (
 const rspi_channel_t channel) [nodiscard]

```

Deinitialize and disable an RSPI controller-mode channel.

Performs a safe shutdown of the specified RSPI channel previously initialized in controller mode. The deinitialization sequence is ordered to prevent bus glitches: first deasserts CS to release any connected peripheral, then disables SPI (`SPCR.SPE = 0`) to stop clock generation, then gates the module clock via `MSTPCRB` for power savings, and finally clears internal state (CS pin config and initialization flag). Register protection (`PRCR`) is temporarily unlocked for module stop control.

This function is safe to call on channels that were never initialized in controller mode; it will still disable the hardware and clear the state.

#### Parameters

|    |         |                                                                                                                                        |
|----|---------|----------------------------------------------------------------------------------------------------------------------------------------|
| in | channel | RSPI channel number (valid: <code>k_rspi_channel_0</code> , <code>k_rspi_channel_1</code> , <code>k_rspi_channel_2</code> ; range 0-2) |
|----|---------|----------------------------------------------------------------------------------------------------------------------------------------|

## Returns

`rx_err_t` Error code indicating success or failure

## Return values

|                                   |                                                                     |
|-----------------------------------|---------------------------------------------------------------------|
| <code>k_rx_ok</code>              | Channel successfully deinitialized and module stopped               |
| <code>k_rx_err_invalid_arg</code> | channel $\geq 3$ or RSPI base address lookup failed for the channel |

## Precondition

channel must be in range [0, 2] (`k_rspi_channel_0` through `k_rspi_channel_2`)

No active SPI transfer should be in progress on this channel

## Postcondition

CS GPIO deasserted (driven high) if channel was initialized

RSPI peripheral disabled (`SPCR.SPE = 0`)

Module clock gated (`MSTPCRB` module stop bit set)

`s_rspi_cs_config[channel]` cleared to defaults (port=0, pin=0)

`s_rspi_controller_initialized[channel]` set to false

## Note

Not thread-safe. Caller must ensure no concurrent transfers or accesses to the same channel during deinitialization.

## See also

[rspi\\_init\\_controller\(\)](#) Reinitialize channel after deinit

[rspi\\_deinit\(\)](#) Deinit for peripheral-mode channels

## Since

Version 1.0.0

Deinitialize and disable an RSPI controller-mode channel.

Disables the RSPI controller, deasserts chip select, clears configuration, and stops the module to reduce power consumption.

## Precondition

Should be called after [rspi\\_init\\_controller\(\)](#) to properly clean up

## Postcondition

If successful:

- CS is deasserted via `rspi_controller_set_cs(channel, false)`
- RSPI is disabled (`rspi->spr = k_rspi_spr_disabled`)
- Module clock is stopped via `internal_set_mstpcrb_for_channel()`
- `s_rspi_cs_config[channel]` is cleared (`port=0, pin=0`)
- `s_rspi_controller_initialized[channel] = false`
- Register protection is unlocked/locked via `*prcr_reg()`

## Note

Thread-safe only if caller ensures no concurrent access to the same channel

#### 8.1.5.64 rspi\_controller\_set\_cs()

```

rx_err_t rspi_controller_set_cs (
 const rspi_channel_t channel,
 const bool active) \[nodiscard\]

```

Set chip select line state for an RSPI controller-mode channel.

Controls the GPIO chip select pin associated with the specified RSPI channel operating in controller mode. The CS signal is active-low: when active is true, the GPIO pin is driven low (CS asserted, peripheral selected); when active is false, the pin is driven high (CS deasserted, peripheral released). The port and pin are read from the internal `s_rspi_cs_config[]` array populated during [rspi\\_init\\_controller\(\)](#).

This function provides direct CS control for protocols that require multi-transfer CS framing. For single 16-bit transfers with automatic CS handling, use [rspi\\_controller\\_transfer\\_16bit\(\)](#) instead.

## Parameters

|    |         |                                                                                                                                        |
|----|---------|----------------------------------------------------------------------------------------------------------------------------------------|
| in | channel | RSPI channel number (valid: <code>k_rspi_channel_0</code> , <code>k_rspi_channel_1</code> , <code>k_rspi_channel_2</code> ; range 0-2) |
| in | active  | true to assert CS (drive GPIO low), false to deassert CS (drive GPIO high)                                                             |

## Returns

`rx_err_t` Error code indicating success or failure

## Return values

|                                     |                                                                                                           |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>k_rx_ok</code>                | CS line successfully driven to requested state                                                            |
| <code>k_rx_err_invalid_state</code> | channel $\geq 3$ or channel not initialized in controller mode via <a href="#">rspi_init_controller()</a> |
| <code>k_rx_err_invalid_arg</code>   | GPIO port base address lookup failed for the stored CS port configuration                                 |

## Precondition

channel must be initialized via [rspi\\_init\\_controller\(\)](#)

`s_rspi_cs_config[channel]` must contain valid port/pin from init

## Postcondition

GPIO PODR bit for the CS pin reflects the requested state

No other GPIO pins on the same port are modified (read-modify-write)

## Note

Not thread-safe. Caller must provide external synchronization when accessing the same channel or GPIO port from multiple threads.

Here is the caller graph for this function:

#### 8.1.5.65 rspi\_controller\_transfer\_16bit()

```

rx_err_t rspi_controller_transfer_16bit (
 const rspi_channel_t channel,
 const uint16_t tx_data,
 uint16_t *const rx_data) [nodiscard]

```

Perform a 16-bit full-duplex SPI transfer in controller mode with automatic CS.

Executes a single 16-bit SPI transfer with full chip select lifecycle management. The transfer sequence is:

1. Assert CS (drive low) with ~300 ns setup delay
2. Wait for TX buffer empty, write 16-bit tx\_data to SPDR
3. Wait for RX buffer full, read 16-bit response from SPDR
4. Clear SPSR status flags (SPRF, OVRF)
5. Apply ~300 ns hold delay, then deassert CS (drive high)

On transfer error (timeout), CS is forcibly deasserted before returning to avoid leaving the peripheral in a selected state. The CS setup and hold delays use cycle-accurate NOP loops calibrated for 240 MHz core clock.

#### Parameters

|     |         |                                                                                              |
|-----|---------|----------------------------------------------------------------------------------------------|
| in  | channel | RSPI channel number (valid: k_rspi_channel_0, k_rspi_channel_1, k_rspi_channel_2; range 0-2) |
| in  | tx_data | 16-bit data word to transmit                                                                 |
| out | rx_data | Pointer to store the received 16-bit response (must not be nullptr)                          |

#### Returns

rx\_err\_t Error code indicating success or failure

#### Return values

|         |                                                               |
|---------|---------------------------------------------------------------|
| k_rx_ok | Transfer completed, *rx_data contains response, CS deasserted |
|---------|---------------------------------------------------------------|

|                                     |                                                                                                             |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>k_rx_err_null_ptr</code>      | rx_data pointer is nullptr                                                                                  |
| <code>k_rx_err_invalid_state</code> | channel $\geq 3$ or channel not initialized via <a href="#">rspi_init_controller()</a>                      |
| <code>k_rx_err_invalid_arg</code>   | RSPI base address lookup failed, or GPIO port lookup failed during CS assertion/deassertion                 |
| <code>k_rx_err_timeout</code>       | TX buffer did not empty or RX buffer did not fill within the 10 ms timeout (CS is deasserted on this error) |

#### Precondition

channel must be initialized via [rspi\\_init\\_controller\(\)](#)

rx\_data must be a valid non-null pointer

#### Postcondition

\*rx\_data contains received 16-bit value on success

CS is deasserted (GPIO driven high) on both success and error

SPSR status flags SPRF and OVRF are cleared on success

#### Note

Not thread-safe. Caller must provide external synchronization when accessing the same channel from multiple threads.

[rspi\\_controller\\_set\\_cs\(\)](#) Manual CS control for multi-transfer framing

[rspi\\_controller\\_deinit\(\)](#) Deinitialize controller-mode channel

#### Since

Version 1.0.0

Perform a 16-bit full-duplex SPI transfer in controller mode with automatic CS.

Executes a full-duplex 16-bit SPI transfer with automatic chip select assertion/deassertion and timing delays.

#### Sequence:

1. Assert CS (active low) with setup delay ( $\sim 300\text{ns}$ )
2. Wait for TX buffer ready, then transmit 16-bit data
3. Wait for RX buffer full, then read 16-bit response
4. Hold CS for minimum hold time ( $\sim 300\text{ns}$ )
5. Deassert CS (inactive high)
6. Clear status flags

## Precondition

Channel must be initialized via [rspi\\_init\\_controller\(\)](#)  
 rx\_data must be a valid non-nullptr

## Postcondition

If successful:

- rx\_data is filled with received 16-bit value
- Status flags (SPRF, OVRF) are cleared
- CS is deasserted (high)

On error:

- CS is deasserted if possible
- rx\_data contents are undefined

## Note

CS setup delay: k\_rspi\_cs\_setup\_delay NOP loops (~300ns)

CS hold delay: k\_rspi\_cs\_hold\_delay NOP loops (~300ns)

Uses inline assembly NOP for precise timing control

Here is the call graph for this function:

### 8.1.5.66 rspi\_deinit()

```
rx_err_t rspi_deinit (
 const rspi_channel_t channel) [nodiscard]
```

Deinitialize and disable an RSPI peripheral-mode channel.

Performs a safe shutdown of the specified RSPI channel previously initialized in peripheral mode. The deinitialization sequence disables SPI bus activity (SPCR.SPE = 0), gates the module clock via MST-PCRB to reduce power consumption, and clears the internal initialization flag. Register protection (PRCR) is temporarily unlocked for module stop control.

This function is safe to call on channels that were never initialized; it will still disable the hardware and clear the init flag. To reinitialize a channel after deinit, call [rspi\\_init\\_peripheral\(\)](#) again.

#### Parameters

|    |         |                                                                                              |
|----|---------|----------------------------------------------------------------------------------------------|
| in | channel | RSPI channel number (valid: k_rspi_channel_0, k_rspi_channel_1, k_rspi_channel_2; range 0-2) |
|----|---------|----------------------------------------------------------------------------------------------|

## Returns

`rx_err_t` Error code indicating success or failure

## Return values

|                                   |                                                                     |
|-----------------------------------|---------------------------------------------------------------------|
| <code>k_rx_ok</code>              | Channel successfully deinitialized and module stopped               |
| <code>k_rx_err_invalid_arg</code> | channel $\geq 3$ or RSPI base address lookup failed for the channel |

## Precondition

channel must be in range  $[0, 2]$  (`k_rspi_channel_0` through `k_rspi_channel_2`)

No active SPI transfer should be in progress on this channel

## Postcondition

RSPI peripheral disabled (`SPCR.SPE = 0`)

Module clock gated (`MSTPCRB` module stop bit set)

`s_rspi_channel_initialized[channel]` set to false

## Note

Not thread-safe. Caller must ensure no concurrent transfers or accesses to the same channel during deinitialization.

## See also

[rspi\\_init\\_peripheral\(\)](#) Reinitialize channel after deinit

[rspi\\_controller\\_deinit\(\)](#) Deinit for controller-mode channels

## Since

Version 1.0.0

Deinitialize and disable an RSPI peripheral-mode channel.

Disables the specified RSPI channel, clears the initialization flag, and optionally disables the module (via module stop bit) to reduce power consumption.

## Precondition

Channel should have been initialized via [rspi\\_init\\_peripheral\(\)](#) previously

## Postcondition

If successful:

- RSPI peripheral is disabled (SPCR.SPE = 0)
- `s_rspi_channel_initialized[channel]` is set to false
- Channel is no longer available for SPI operations

Here is the call graph for this function:

8.1.5.67 `rspi_init_controller()`

```

rx_err_t rspi_init_controller (
 const rspi_channel_t channel,
 const rspi_controller_config_t * config) [nodiscard]

```

Initialize RSPI channel in controller mode for external device communication.

Configures the specified RSPI channel as an SPI controller for communicating with external SPI peripheral devices such as sensors. Performs argument validation, SPBR bit rate calculation, CS GPIO pin configuration, and full hardware register setup following the RX72N Hardware Manual Section 38.3.6 initialization sequence. Always configures 16-bit data frames with word access mode.

The initialization is split into three internal phases: argument validation, hardware resource preparation (SPBR calculation, base address lookup, GPIO setup), and register configuration (module clock enable, SPI mode, bit rate, SPI enable). On any failure, no partial hardware state is left behind.

## Parameters

|    |         |                                                                                                                                                                                                                                                                                                                                                        |
|----|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| in | channel | RSPI channel number (valid: <code>k_rspi_channel_0</code> , <code>k_rspi_channel_1</code> , <code>k_rspi_channel_2</code> ; range 0-2)                                                                                                                                                                                                                 |
| in | config  | Pointer to <code>rspi_controller_config_t</code> containing: <ul style="list-style-type: none"> <li><code>spi_mode</code>: SPI mode (0-3) for CPOL/CPHA configuration</li> <li><code>freq_hz</code>: SPI clock frequency in Hz (100 kHz to 10 MHz)</li> <li><code>cs</code>: GPIO pin for chip select (<code>rx_port_pin_t</code> encoding)</li> </ul> |

## Returns

`rx_err_t` Error code indicating success or failure

## Return values

|                                     |                                                                                                                                                                       |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>k_rx_ok</code>                | Channel successfully initialized in controller mode                                                                                                                   |
| <code>k_rx_err_null_ptr</code>      | config pointer is nullptr                                                                                                                                             |
| <code>k_rx_err_invalid_arg</code>   | channel $\geq 3$ , <code>spi_mode</code> $> 3$ , <code>freq_hz</code> outside 100 kHz - 10 MHz range, RSPI base address lookup failed, or CS GPIO port/pin is invalid |
| <code>k_rx_err_invalid_state</code> | channel already initialized in controller mode (call <code>rspi_controller_deinit()</code> first)                                                                     |

## Precondition

config must be a valid non-null pointer

channel must not already be initialized in controller mode

System clocks must be configured (PCLKB running at 60 MHz)

## Postcondition

RSPI module clock enabled, registers configured, SPI enabled in controller mode (SPCR.MSTR = 1, SPCR.SPE = 1)

CS GPIO configured as output, driven high (inactive / deasserted)

s\_rspi\_controller\_initialized[channel] set to true

## Note

Not thread-safe. Initialize each channel from a single thread during system startup.

## See also

[rspi\\_controller\\_transfer\\_16bit\(\)](#) Perform 16-bit transfers after init

[rspi\\_controller\\_set\\_cs\(\)](#) Manual chip select control

[rspi\\_controller\\_deinit\(\)](#) Deinitialize controller-mode channel

[rspi\\_controller\\_config\\_t](#) Configuration structure

## Since

Version 1.0.0

Initialize RSPI channel in controller mode for external device communication.

Configures the specified RSPI channel as a SPI controller to communicate with SPI peripheral devices. Enables the module, configures clock frequency, SPI mode, and chip select GPIO pin.

## Precondition

config must be non-NULL

channel < k\_rspi\_max\_channels

channel must not be already initialized

CS GPIO port and pin must be valid and available

## Postcondition

If successful:

- RSPI module is enabled via [internal\\_set\\_mstpcrb\\_for\\_channel\(\)](#)
- \*prcr\_reg() is unlocked/locked for register protection
- RSPI registers configured: spbr, spcmd0, spcr, spdcr, sppcr
- CS GPIO configured as output, driven high (inactive)
- s\_rspi\_cs\_config[channel] stores CS port/pin
- s\_rspi\_controller\_initialized[channel] = true

On error:

- Hardware state is unchanged
- Channel remains uninitialized

## Note

Bit rate calculation:  $\text{freq} = \text{PCLKB} / (2 * (\text{SPBR} + 1))$

Always configures 16-bit data frames with word access mode

CS is active-low (asserted=0, deasserted=1)

Definition at line 1339 of file [rspi.c](#).

8.1.5.68 `rspi_init_peripheral()`

```
rx_err_t rspi_init_peripheral (
 rspi_channel_t channel,
 const rspi_config_t * config) [nodiscard]
```

Initialize RSPI channel in peripheral mode for RPi5 communication.

Configures the specified RSPI channel as an SPI peripheral device. In peripheral mode the RX72N receives the clock signal from an external SPI controller (Raspberry Pi 5). Performs full hardware initialization including module stop release, pin function selection (COPI/CIPO/CLK/CS via MPC), SPI mode register configuration, and frame size setup.

## 8.1.5.69 Algorithm

1. Validate channel (0-2) and config pointer
2. Release RSPI module from module stop (MSTPCRB)
3. Disable RSPI (SPCR.SPE = 0)
4. Configure pin functions via MPC (COPI, CIPO, CLK, CS)
5. Set SPI mode (CPOL/CPHA in SPCMD0)
6. Set frame length (8-bit or 16-bit in SPCMD0)
7. Configure as peripheral (SPCR.MSTR = 0)
8. Enable RSPI (SPCR.SPE = 1)

## Parameters

|    |         |                                                                                                                                                                     |
|----|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| in | channel | RSPI channel number (0-2)                                                                                                                                           |
| in | config  | Pointer to peripheral mode configuration <ul style="list-style-type: none"> <li>• Must not be nullptr</li> <li>• config-&gt;spi_mode must be valid (0-3)</li> </ul> |

## Returns

`rx_err_t` Error code indicating success or failure

## Return values

|                                     |                                                                               |
|-------------------------------------|-------------------------------------------------------------------------------|
| <code>k_rx_ok</code>                | Channel successfully initialized in peripheral mode                           |
| <code>k_rx_err_invalid_arg</code>   | Channel > 2 or invalid SPI mode                                               |
| <code>k_rx_err_null_ptr</code>      | config pointer is nullptr                                                     |
| <code>k_rx_err_invalid_state</code> | Channel already initialized (call <code>rspi_deinit()</code> to reinitialize) |

## Precondition

- Channel must not be already initialized (call [rspi\\_deinit\(\)](#) first to reinitialize)
- System clocks must be configured (PCLKB running at expected frequency)

## Postcondition

- RSPI channel configured as SPI peripheral, ready for transfers
- COPI/CIPO/CLK/CS pins configured for SPI peripheral function

## Note

- Thread Safety: NOT thread-safe. Initialize each channel from a single thread during system startup.

## Example: RPi5 Communication Setup

```
rspi_config_t rpi_cfg = {
 .spi_mode = k_rspi_mode_0,
 .use_16bit = false
};
rx_err_t err = rspi_init_peripheral(k_rspi_channel_0, &rpi_cfg);
if (err != k_rx_ok) {
 rx_log_error_val("SPI", "RSPI0 peripheral init failed", err);
}
```

```

rx_err_t rspi_peripheral_read_available (
 const rspi_channel_t channel,
 bool * available) [nodiscard]

```

Check if receive data is available in the RSPi receive buffer.

Polls the RSPi Status Register (SPSR) SPRF flag to determine whether the receive buffer contains data ready for reading. This is a non-blocking status check that returns immediately without waiting for data. Use this to implement polled receive patterns without incurring the overhead of a full transfer call.

##### Parameters

|     |           |                                                                                                             |
|-----|-----------|-------------------------------------------------------------------------------------------------------------|
| in  | channel   | RSPi channel number (valid: k_rspi_channel_0, k_rspi_channel_1, k_rspi_channel_2; range 0-2)                |
| out | available | Pointer to bool set to true if SPRF flag indicates data is available, false otherwise (must not be nullptr) |

##### Returns

rx\_err\_t Error code indicating success or failure

##### Return values

|                        |                                                                                    |
|------------------------|------------------------------------------------------------------------------------|
| k_rx_ok                | Status successfully read into *available                                           |
| k_rx_err_null_ptr      | available pointer is nullptr                                                       |
| k_rx_err_invalid_state | channel >= 3 or channel not initialized via <a href="#">rspi_init_peripheral()</a> |
| k_rx_err_invalid_arg   | RSPi base address lookup failed for the channel                                    |

## Precondition

channel must be initialized via [rspi\\_init\\_peripheral\(\)](#)  
 available must be a valid non-null pointer

## Postcondition

\*available reflects current SPRF flag state on success  
 \*available set to false on RSPI base address lookup failure

## Note

Not thread-safe. Caller must provide external synchronization when accessing the same channel from multiple threads.

#### 8.1.5.71 rspi\_peripheral\_transfer()

```

rx_err_t rspi_peripheral_transfer (
 const rspi_channel_t channel,
 const uint8_t * tx_data,
 uint8_t * rx_data,
 const uint16_t length) [nodiscard]

```

Full-duplex SPI transfer in peripheral mode.

Executes a byte-by-byte full-duplex SPI transfer on the specified RSPI channel operating in peripheral mode. For each byte, the function waits for the transmit buffer to empty, writes the TX byte, waits for the receive buffer to fill, then reads the RX byte. Both TX and RX wait operations are bounded by a 10 ms timeout to prevent infinite loops.

The transfer loop is bounded by `k_rspi_transfer_len_max` (65535) per NASA Rule 2 to ensure statically provable loop termination.

#### Parameters

|     |         |                                                                                                                                        |
|-----|---------|----------------------------------------------------------------------------------------------------------------------------------------|
| in  | channel | RSPI channel number (valid: <code>k_rspi_channel_0</code> , <code>k_rspi_channel_1</code> , <code>k_rspi_channel_2</code> ; range 0-2) |
| in  | tx_data | Pointer to transmit data buffer (must not be nullptr)                                                                                  |
| out | rx_data | Pointer to receive data buffer (must not be nullptr, must have capacity for at least length bytes)                                     |
| in  | length  | Number of bytes to transfer (valid: 1 to 65535)                                                                                        |

#### Returns

`rx_err_t` Error code indicating success or failure

#### Return values

|                                     |                                                                                       |
|-------------------------------------|---------------------------------------------------------------------------------------|
| <code>k_rx_ok</code>                | Transfer completed successfully, <code>rx_data</code> filled                          |
| <code>k_rx_err_null_ptr</code>      | <code>tx_data</code> or <code>rx_data</code> pointer is nullptr                       |
| <code>k_rx_err_invalid_arg</code>   | length is zero, or RSPI base address lookup failed for the channel                    |
| <code>k_rx_err_invalid_state</code> | channel $\geq 3$ or channel not initialized via <code>rspi_init_peripheral()</code>   |
| <code>k_rx_err_timeout</code>       | Transmit buffer did not empty or receive buffer did not fill within the 10 ms timeout |

#### Precondition

channel must be initialized via [rspi\\_init\\_peripheral\(\)](#)  
tx\_data and rx\_data must be valid non-null pointers  
length must be in range [1, 65535]

#### Postcondition

rx\_data buffer contains received bytes corresponding to each transmitted byte offset on success  
SPSR status flags (SPRF, OVRF) cleared after each byte transfer

#### Note

Not thread-safe. Caller must provide external synchronization when accessing the same channel from multiple threads.

8.1.5.72 `rspi_peripheral_write_ready()`

```
rx_err_t rspi_peripheral_write_ready (
 const rspi_channel_t channel,
 bool * ready) [nodiscard]
```

Check if the RSPi transmit buffer is ready for new data.

Polls the RSPi Status Register (SPSR) SPTEF flag to determine whether the transmit buffer is empty and ready to accept new data. This is a non-blocking status check that returns immediately without waiting for the buffer to drain. Use this to implement polled transmit patterns or to verify readiness before writing to the SPI data register.

## Parameters

|     |         |                                                                                                                                        |
|-----|---------|----------------------------------------------------------------------------------------------------------------------------------------|
| in  | channel | RSPi channel number (valid: <code>k_rspi_channel_0</code> , <code>k_rspi_channel_1</code> , <code>k_rspi_channel_2</code> ; range 0-2) |
| out | ready   | Pointer to bool set to true if SPTEF flag indicates the transmit buffer is empty, false otherwise (must not be nullptr)                |

## Returns

`rx_err_t` Error code indicating success or failure

## Return values

|                                     |                                                                                        |

Here is the call graph for this function:

## 8.1.5.73 timer`get`count()

```
rx_err_t timer_get_count (
 uint16_t * count) [nodiscard]
```

Get current CMT0 counter value.

Reads the 16-bit free-running counter register (CMCNT) from CMT0. The counter increments at PCLKB/8 rate and resets to 0 on compare match with CMCOR. This can be used for sub-tick timing measurements or to check elapsed time within a 10 ms system tick period. Works whether the timer is running or stopped.

## Parameters

| out | count | Pointer to store 16-bit counter value                                                                                                                                                                |
|-----|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     |       | <ul style="list-style-type: none"> <li>• Must point to valid uint16_t variable</li> <li>• Value range: 0 to CMCOR (compare match constant)</li> <li>• Unchanged if function returns error</li> </ul> |

## Returns

rx\_err\_t Error code indicating success or failure

## Return values

|                   |                                                      |
|-------------------|------------------------------------------------------|
| k_rx_ok           | Counter value successfully read and stored in *count |
| k_rx_err_null_ptr | count pointer is nullptr                             |

## Precondition

count pointer must be valid (not nullptr)

CMT0 must have been initialized via [timer\\_init\(\)](#) for meaningful values

## Postcondition

\*count contains current CMCNT register value if function succeeds

\*count unchanged if function returns error

## Note

Thread Safety: NOT thread-safe. The 16-bit register read is atomic on RX72N but the pointer write is not protected.

## Example: Sub-Tick Timing

```
uint16_t start, end;
timer_get_count(&start);
// ... perform operation ...
timer_get_count(&end);
uint16_t elapsed_ticks = (end >= start) ? (end - start) : (0xFFFF - start + end);
```

See also

[timer\\_init\(\)](#) Initialize CMT0 timer

[timer\\_stop\(\)](#) Stop CMT0 timer

Since

Version 1.0.0

Get current CMT0 counter value.

Reads the current value of CMT0.CMCNT register, which increments from 0 to CMCOR (4687) at 468.75 kHz. This provides sub-millisecond timing resolution for diagnostics, performance measurement, and jitter analysis.

Algorithm steps:

1. Validate count pointer is not nullptr
2. Validate CMT0 hardware accessibility
3. Read CMCNT register (atomic 16-bit read)
4. Validate count is within expected range (0-4687)
5. Store count value to output parameter

Counter behavior:

- Increments every  $1/(1.875 \text{ MHz}) = 0.533 \text{ us}$
- Resets to 0 when reaching CMCOR (18749)
- Wraps every 10 ms (one system tick)
- Can be read at any time without affecting timer operation

Timing resolution:

$$\text{Resolution} = \frac{1}{f_{CMT}} = \frac{1}{1875000 \text{ Hz}} = 0.533 \text{ us}$$

Maximum readable value:

$$\text{Max count} = CMCOR = 18749 \approx 10 \text{ ms}$$

Return Value Details:

| Return Value         | Condition                            | *count Value |
|----------------------|--------------------------------------|--------------|
| k_rx_ok              | Normal operation                     | 0 to 18749   |
| k_rx_err_null_ptr    | count == nullptr                     | Unchanged    |
| k_rx_err_hw_unmapped | <a href="#">cmt0()</a> returned NULL | Unchanged    |

| Return Value      | Condition     | *count Value  |
|-------------------|---------------|---------------|
| k_rx_err_hw_error | *count > 4687 | Invalid value |

#### Precondition

`timer_init()` must have been called successfully  
count pointer must be valid and non-NULL

#### Postcondition

If `k_rx_ok`: \*count contains current CMCNT value (0-4687)  
If error: \*count unchanged (nullptr) or contains invalid value (hw\_error)  
Timer operation not affected (read-only access)

#### Invariant

Return value `k_rx_ok` guarantees \*count in [0, 18749]

#### Note

Thread Safety: Thread-safe for reading. Multiple threads can call simultaneously. CMCNT is atomic 16-bit register on RX72N. No need for mutual exclusion.

Re-entrancy: Fully reentrant. Safe to call from ISRs and tasks concurrently. No shared state modified.

Performance: Executes in ~500 ns @ 240 MHz (single register read). Suitable for high-frequency polling.

Memory: No heap allocation. Stack usage: ~4 bytes (local variable).

#### Warning

Counter wraps: Counter resets to 0 every 10 ms. For measuring intervals longer than 10 ms, use ThreadX system time (`tx_time_get`) instead.

Race condition: Counter value is snapshot at time of read. By the time caller processes value, hardware counter has advanced. Don't assume static value.

#### Example - Basic Usage:

```
uint16_t count;
rx_err_t err = timer_get_count(&count);
if (err == k_rx_ok) {
 // Convert to microseconds: count * 0.533 us
 float us = count * 0.533f;
 rx_log_info("TIMER", "Current time in tick: %.1f us", us);
}
```

## Example - Performance Measurement:

```
// Measure execution time of function (sub-tick resolution)
uint16_t start, end;
timer_get_count(&start);

// Execute function to measure
motor_update();

timer_get_count(&end);

// Calculate elapsed time (handle wrap)
uint16_t elapsed;
if (end >= start) {
 elapsed = end - start;
} else {
 elapsed = (18749 - start) + end; // Wrapped
}

float us = elapsed * 0.533f;
rx_log_info("PERF", "motor_update took %.1f us", us);
```

## Example - Jitter Analysis:

```
// Measure interrupt jitter
static uint16_t last_count = 0;

void analyze_jitter(void)
{
 uint16_t current;
 timer_get_count(¤t);

 int16_t jitter = current - last_count;
 if (abs(jitter) > 10) { // >21 us jitter
 rx_log_warn("TIMER", "High jitter detected: %d counts", jitter);
 }

 last_count = current;
}
```

## Example - Error Handling:

```
uint16_t count;
rx_err_t err = timer_get_count(&count);
switch (err) {
 case k_rx_ok:
 // Normal operation
 break;
 case k_rx_err_null_ptr:
 rx_log_error("TIMER", "Invalid pointer");
 return err;
 case k_rx_err_hw_unmapped:
 rx_log_error("TIMER", "CMT0 not initialized");
 return err;
 case k_rx_err_hw_error:
 rx_log_error("TIMER", "Counter overflow: %u", count);
 return err;
}
```

Here is the call graph for this function:

## 8.1.5.74 timer\_init()

```

rx_err_t timer_init (
 void) [nodiscard]
```

Initialize CMT0 for ThreadX system tick (100 Hz).

Configures Compare Match Timer channel 0 (CMT0) to generate periodic interrupts at 100 Hz (10 ms interval) for the ThreadX RTOS system tick. Performs full hardware initialization including module stop release, clock source selection (PCLKB/8), compare match constant calculation, and interrupt priority setup.

### 8.1.5.75 Algorithm

1. Release CMT0 from module stop (MSTPCRA.MSTPA15 = 0)
2. Stop counter (CMSTR0.STR0 = 0)
3. Configure CMCR: PCLKB/8 clock source, compare match interrupt enable
4. Calculate CMCOR from PCLKB frequency and desired 100 Hz rate
5. Clear counter (CMCNT = 0)
6. Set compare match value (CMCOR)
7. Configure interrupt priority (IPR = 5)
8. Start counter (CMSTR0.STR0 = 1)

### Returns

rx\_err\_t Error code indicating success or failure

### Return values

|                        |                                                     |
|------------------------|-----------------------------------------------------|
| k_rx_ok                | CMT0 successfully initialized and running at 100 Hz |
| k_rx_err_invalid_state | CMT0 already initialized                            |

### Precondition

System clocks must be configured (PCLKB running at expected frequency)  
 CMT0 must not be already initialized (call [timer\\_stop\(\)](#) first to reinitialize)

### Postcondition

CMT0 generating 100 Hz interrupts for ThreadX system tick  
 CMT0 interrupt enabled at priority 5

### Note

Thread Safety: NOT thread-safe. Must be called once during system initialization before ThreadX is started.

### Example: System Initialization

```
void hardware_init(void) {
 rx_err_t err = timer_init();
 if (err != k_rx_ok) {
 rx_log_error_val("TIMER", "CMT0 init failed", err);
 return;
 }
 rx_log_info("TIMER", "System tick running at 100 Hz");
}
```

[timer\\_get\\_count\(\)](#) Read current counter value

Since

Version 1.0.0

Initialize CMT0 for ThreadX system tick (100 Hz).

Configures the RX72N CMT0 (Compare Match Timer 0) peripheral to generate precise periodic interrupts at 100.00 Hz for ThreadX RTOS scheduling. This function must be called during system initialization, before starting ThreadX kernel.

Algorithm steps:

1. Validate CMT0 and CMT\_CTRL hardware accessibility
2. Stop CMT0 if currently running (safe reconfiguration)
3. Configure CMCR register: PCLKB/128 clock, interrupt enabled
4. Set CMCOR compare match value: 4687 (for 100 Hz)
5. Reset CMCNT counter to 0 (known initial state)
6. Configure ICU: clear pending interrupt, set priority, enable interrupt
7. Start CMT0 timer
8. Enable global interrupts (PSW I-flag)
9. Verify timer started successfully

Configuration summary:

- Clock source: PCLKB = 60 MHz
- Divider: /32 -> 1.875 MHz
- Compare value: 18749 -> 100.00 Hz
- Interrupt priority: 3/15 (higher than app tasks, lower than motor control)
- Tick period: 10.000 ms (exact, zero drift)

Hardware configuration sequence:

Return Value Details:

| Return Value           | Condition                                                          |
|------------------------|--------------------------------------------------------------------|
| k_rx_ok                | Timer initialized successfully                                     |
| k_rx_err_invalid_state | <a href="#">cmt_ctrl()</a> or <a href="#">cmt0()</a> returned NULL |
| k_rx_err_hw_error      | CMSTR0 start bit failed to set                                     |

#### Precondition

- System clocks must be configured (PCLKB = 60 MHz)
- CMT0 must not be in use by another module
- Must be called before [tx\\_kernel\\_enter\(\)](#)
- Interrupts can be disabled (function enables at end)

#### Postcondition

- CMT0 running at 100 Hz, generating periodic interrupts
- [cmt0\\_isr\(\)](#) will be called every 10 ms
- ThreadX system tick operational
- Global interrupts enabled (PSW I-flag set)

#### Invariant

- CMT0 compare value = 4687 (100.00 Hz)
- CMT0 interrupt priority = 3/15

## Note

Thread Safety: Not thread-safe. Must be called during single-threaded initialization before ThreadX kernel starts. Do not call from running RTOS tasks.

Re-entrancy: Not reentrant. Calling multiple times without `timer_stop()` is undefined behavior (timer will be reconfigured).

Performance: Initialization takes ~10 us @ 240 MHz (multiple register writes). This is one-time startup cost, not runtime overhead.

Memory: Zero heap allocation. All configuration is register I/O.

## Warning

Call order critical: Must call `timer_init()` BEFORE `tx_kernel_enter()`. ThreadX depends on system tick being operational. Calling after kernel start causes undefined behavior.

Clock dependency: Assumes PCLKB = 60 MHz. If system clock configuration changes, `k_cmt0←_compare_match` must be recalculated. Incorrect clock frequency causes incorrect tick rate.

## Attention

Global interrupt enable: This function enables global interrupts via "setpsw i". If interrupts were intentionally disabled, they will be enabled after this call.

## Example - System Initialization:

```
#include "timer.h"
#include "tx_api.h"

int main(void)
{
 // 1. Initialize hardware (clocks, GPIO, etc.)
 hardware_init();

 // 2. Initialize system tick BEFORE ThreadX
 rx_err_t err = timer_init();
 if (err != k_rx_ok) {
 rx_log_error("MAIN", "System tick init failed: %d", err);
 while (1) {} // Halt on critical error
 }

 // 3. Define ThreadX application
 tx_application_define(NULLptr);

 // 4. Start ThreadX kernel (never returns)
 tx_kernel_enter();
}
```

## Example - Error Handling:

```
// Robust initialization with error checking
rx_err_t err = timer_init();
switch (err) {
 case k_rx_ok:
 rx_log_info("MAIN", "System tick running at 100 Hz");
 break;
 case k_rx_err_invalid_state:
 rx_log_error("MAIN", "Clock not configured - check hardware_init()");
 return err;
 case k_rx_err_hw_error:
 rx_log_error("MAIN", "CMT0 hardware fault");
 return err;
 default:
 rx_log_error("MAIN", "Unexpected error: %d", err);
 return err;
}
```

Example - Verification:

```
// After initialization, verify tick is running
timer_init();

uint16_t count1, count2;
timer_get_count(&count1);
tx_thread_sleep(50); // Sleep 500ms (50 ticks)
timer_get_count(&count2);

// Counter should have rolled over ~50 times
rx_log_info("MAIN", "Tick verified: count changed from %u to %u", count1, count2);
```

Here is the call graph for this function:

#### 8.1.5.76 timer\_stop()

```

rx_err_t timer_stop (
 void) [nodiscard]

```

Stop CMT0 timer and disable compare match interrupts.

Halts the CMT0 counter by clearing the start bit (CMSTR0.STR0 = 0) and disables the compare match interrupt. The counter value is preserved and can be read via [timer\\_get\\_count\(\)](#). After stopping, [timer\\_init\(\)](#) may be called to restart the timer.

### 8.1.5.77 Algorithm

1. Disable compare match interrupt (CMCR.CMIE = 0)
2. Stop counter (CMSTR0.STR0 = 0)
3. Mark timer as stopped in internal state

#### Returns

`rx_err_t` Error code indicating success or failure

#### Return values

|                                     |                           |
|-------------------------------------|---------------------------|
| <code>k_rx_ok</code>                | CMT0 successfully stopped |
| <code>k_rx_err_invalid_state</code> | CMT0 was not initialized  |

#### Precondition

CMT0 must have been initialized via [timer\\_init\(\)](#)

Caller must ensure stopping the system tick will not break RTOS scheduling

#### Postcondition

CMT0 counter halted, counter value preserved

Compare match interrupts disabled

#### Note

Thread Safety: NOT thread-safe. Stopping the system tick from a ThreadX thread may cause scheduling to freeze.

#### Warning

Stopping CMT0 halts the ThreadX system tick. Only stop during shutdown or low-power entry.

#### Example: Entering Low Power Mode

```
void enter_low_power(void) {
 rx_err_t err = timer_stop();
 if (err != k_rx_ok) {
 rx_log_error_val("TIMER", "Failed to stop timer", err);
 return;
 }
 // Enter low-power mode
}
```

#### See also

[timer\\_init\(\)](#) Reinitialize CMT0 after stopping

[timer\\_get\\_count\(\)](#) Read counter value (works while stopped)

Since

Version 1.0.0

Stop CMT0 timer and disable compare match interrupts.

Halts the CMT0 timer by clearing the start bit in CMSTR0 register. This stops the system tick interrupts, effectively freezing ThreadX scheduling and time tracking. Use only during system shutdown or for testing.

Algorithm steps:

1. Validate CMT\_CTRL hardware accessibility
2. Check if timer is currently running
3. Clear CMSTR0 start bit to stop counter
4. Verify timer stopped successfully

Use cases:

- System shutdown sequence
- Power management (entering low-power mode)
- Testing and diagnostics
- Emergency stop during fault condition

Warning

Stopping system tick will freeze ThreadX scheduler. All time-based operations (tx\_thread\_sleep, timeouts) will hang. Only call during controlled shutdown or with ThreadX suspended.

Precondition

[timer\\_init\(\)](#) must have been called successfully

CMT0 should be running (otherwise returns k\_rx\_err\_invalid\_state)

Postcondition

CMT0 timer stopped, CMCNT frozen

No more [cmt0\\_isr\(\)](#) interrupts will occur

ThreadX time tracking frozen (system time no longer increments)

Note

Thread Safety: Not thread-safe. Should only be called from single-threaded shutdown sequence or with ThreadX suspended.

Performance: Executes in ~1 us @ 240 MHz (register read/write).

Example - Controlled Shutdown:

```
// Shutdown sequence
tx_thread_suspend(&all_app_threads); // Suspend all app threads

rx_err_t err = timer_stop();
if (err != k_rx_ok) {
 rx_log_error("SHUTDOWN", "Failed to stop timer: %d", err);
}

// System is now halted, safe to power down
```

Here is the call graph for this function:

#### 8.1.5.78 `uart_clear_rx_errors()`

```
rx_err_t uart_clear_rx_errors (
 uart_channel_t channel) [nodiscard]
```

Clear sticky receive error flags (ORER/FER/PER) on a UART channel.

Reads SSR and writes back with the receive error bits masked to 0. Per HUM 34.2.7, those flags must be cleared before the receiver will latch further bytes. The RXI ISR clears them on every byte; this helper is the periodic-fallback path when an error latches without RDRF firing (e.g. line glitch on an idle bus).

## Parameters

|    |         |                     |
|----|---------|---------------------|
| in | channel | SCI channel (0-12). |
|----|---------|---------------------|

## Returns

k\_rx\_ok on success, k\_rx\_err\_invalid\_arg if channel is invalid.

Definition at line 1834 of file [uart.c](#).

```
01835 {
01836 if ((uint8_t)channel >= k_uart_max_channels) {
01837 return k_rx_err_invalid_arg;
01838 }
01839 volatile rx_sci_regs_t* sci = sci_get_channel(channel);
01840 if (sci == nullptr) {
01841 return k_rx_err_invalid_arg;
01842 }
01843 const uint8_t ssr = sci->ssr;
01844 if ((ssr & k_sci_ssr_error_mask) != k_uart_flag_clear) {
01845 sci->ssr = (uint8_t)(ssr & ~k_sci_ssr_error_mask);
01846 }
01847 return k_rx_ok;
01848 }
```

References [k\\_sci\\_ssr\\_error\\_mask](#), [k\\_uart\\_flag\\_clear](#), [k\\_uart\\_max\\_channels](#), [sci\\_get\\_channel\(\)](#), and [rx\\_sci\\_regs\\_t::ssr](#).

Here is the call graph for this function:

#### 8.1.5.79 `uart_debug_init()`

```
rx_err_t uart_debug_init (
 void) [nodiscard]
```

Initialize debug UART (SCI9, 115200 bps, 8N1).

Convenience wrapper for `uart_init_channel(k_uart_debug_channel, 115200)`. Used by `rx_log` for early boot logging before ThreadX is initialized.

### Returns

k\_rx\_ok on success, error code on failure

Initialize debug UART (SCI9, 115200 bps, 8N1).

Convenience function to initialize SCI9 with default debug settings:

- Channel: SCI9
- Baud rate: 115200 bps
- TX pin: PB7 (TXD9)
- RX pin: PB6 (RXD9)
- Format: 8N1 (8 data bits, no parity, 1 stop bit)

SCI9 is connected to the CY7C65213 USB-UART bridge on the STAR PCB, providing a virtual COM port when connected via USB.

### Algorithm steps:

1. Create `uart_channel_config_t` with default values
2. Call `uart_init_channel()` with the configuration
3. Return result

### Precondition

System clocks must be initialized (PCLKB = 60 MHz)

SCI9 must not be already initialized

### Postcondition

SCI9 configured and ready for TX/RX at 115200 baud

`uart_debug_puts()`, `uart_debug_putc()` etc. are functional

### Note

Call once during early system initialization

Call before any other debug output functions

### Warning

Must be called before ThreadX starts if debug output is needed during init

### Thread Safety:

Not thread-safe. Call once during startup before ThreadX.

Performance:

- Execution time: ~50 us
- Stack usage: 64 bytes

Example:

```
void system__init(void)
{
 // Initialize clocks first
 rx_clock_init();

 // Initialize debug UART for early output
 rx_err_t err = uart_debug_init();
 if (err != k_rx_ok) {
 // Cannot print error - no UART!
 // Could blink LED or set error flag
 return;
 }

 // Now we can print debug messages
 uart_debug_puts("[INFO] System starting...\n");
}
```

[uart\\_debug\\_putc\(\)](#) Debug character output

Since

Version 1.0.0

Definition at line 1977 of file [uart.c](#).

```
01978 {
01979 const uart_channel_config_t config = {
01980 .channel = (uart_channel_t)k_uart_debug_channel,
01981 .baudrate = k_uart_default_baudrate,
01982 .tx_gpio = (rx_port_pin_t)k_uart_debug_tx_gpio,
01983 .rx_gpio = (rx_port_pin_t)k_uart_debug_rx_gpio,
01984 };
01985 return uart_init_channel(&config);
01986 }
```

References [k\\_uart\\_debug\\_channel](#), [k\\_uart\\_debug\\_rx\\_gpio](#), [k\\_uart\\_debug\\_tx\\_gpio](#), [k\\_uart\\_default\\_baudrate](#), and [uart\\_init\\_channel\(\)](#).

Here is the call graph for this function:

### 8.1.5.80 uart\_debug\_putc()

```
void uart_debug_putc (
 const char data)
```

Transmit a single character on debug UART (SCI9).

#### Parameters

|    |      |                       |
|----|------|-----------------------|
| in | data | Character to transmit |
|----|------|-----------------------|

Transmit a single character on debug UART (SCI9).

Convenience wrapper around [uart\\_putc\\_channel\(\)](#) for the fixed debug channel (SCI9). Errors are silently ignored to allow use in early initialization contexts where error propagation is not yet possible.

Algorithm steps:

1. Call `uart_putc_channel(k_uart_debug_channel, data)`
2. Cast return value to (void) - errors discarded

#### Precondition

[uart\\_debug\\_init\(\)](#) must have been called successfully  
SCI9 must be initialized and TX enabled

#### Postcondition

Character written to SCI9 TDR and transmission started  
Any errors are silently discarded

#### Note

Error return from [uart\\_putc\\_channel\(\)](#) is intentionally discarded  
For error-checked output use [uart\\_putc\\_channel\(\)](#) directly

#### Warning

Only available when `RX_IS_SIMULATOR` is 0 (hardware builds)

#### Thread Safety:

Not safe for concurrent access on SCI9 without external mutex.

#### Performance:

- Execution time: ~90 us @ 115200 baud
- Stack usage: 16 bytes

#### Example:

```
uart_debug_putc('A'); // Send 'A'
uart_debug_putc('\r'); // Carriage return
uart_debug_putc('\n'); // Line feed
```

#### See also

#### 8.1.5.81 uart\_debug\_puthex()

```
void uart_debug_puthex (
 const uint32_t value,
 uint8_t digits)
```

Print a hexadecimal value on debug UART (SCI9).

Parameters

|    |        |                            |
|----|--------|----------------------------|
| in | value  | Value to print             |
| in | digits | Number of hex digits (1-8) |

Print a hexadecimal value on debug UART (SCI9).

Transmits "0x" prefix followed by the specified number of uppercase hex digits of value on SCI9. Digits are always printed most-significant first. The digits parameter is clamped to [k\_uart\_hex\_min\_digits, k\_uart\_hex\_max\_digits] (1-8) before use.

Algorithm steps:

1. Send "0x" prefix via `uart_debug_puts()`
2. Clamp digits to [1, 8]
3. Iterate nibbles from MSN to LSN (statically bounded by k\_uart\_hex\_max\_digits)
4. For each nibble index < digits, extract nibble and print uppercase hex char

Precondition

`uart_debug_init()` must have been called successfully  
`uart_debug_puts()` and `uart_debug_putc()` must be functional

Postcondition

"0x" followed by digits uppercase hex characters transmitted on SCI9  
digits clamped to [1, 8] if out of range

Note

Uses static lookup table `s_hex[]` for digit-to-character conversion  
Always prefixes output with "0x"

Warning

Only available when `RX_IS_SIMULATOR` is 0 (hardware builds)

Thread Safety:

Not safe for concurrent access on SCI9 without external mutex.

Performance:

- Execution time: ~90 us per character @ 115200 baud
- Stack usage: 24 bytes

Example:

```
uart_debug_puts("Addr: ");
uart_debug_puthex(0xDEADBEEF, 8); // Sends "0xDEADBEEF"
uart_debug_puthex(0x42, 2); // Sends "0x42"
uart_debug_putc('\n');
```

Here is the call graph for this function:

8.1.5.82 `uart_debug_putint()`

```
void uart_debug_putint (
 const int32_t value)
```

Print a signed integer on debug UART (SCI9).

Parameters

|    |       |                        |
|----|-------|------------------------|
| in | value | Integer value to print |
|----|-------|------------------------|

Print a signed integer on debug UART (SCI9).

Converts a signed 32-bit integer to a decimal ASCII string and transmits it on SCI9. Handles INT32\_MIN correctly by using int64\_t for the negation. Uses a fixed-size stack buffer (`k_uart_int_buffer_size` = 12) built in reverse then passed to [uart\\_debug\\_puts\(\)](#).

Algorithm steps:

1. Determine sign; compute `abs_value` as `uint32_t`
2. Null-terminate the buffer end
3. Build digits right-to-left (statically bounded by `k_uart_int_buffer_size`)
4. Prepend '-' if negative
5. Call [uart\\_debug\\_puts\(\)](#) with the resulting substring pointer

Precondition

[uart\\_debug\\_init\(\)](#) must have been called successfully  
[uart\\_debug\\_puts\(\)](#) must be functional

Postcondition

Decimal representation of value transmitted on SCI9  
 Leading zeros suppressed; negative values prefixed with '-'

Note

No return value - output errors are silently discarded  
 Buffer is stack-allocated; safe for re-entrant calls on different tasks

Warning

Only available when `RX_IS_SIMULATOR` is 0 (hardware builds)

Thread Safety:

Not safe for concurrent access on SCI9 without external mutex.

Performance:

- Execution time: ~90 us per digit @ 115200 baud + digit-loop overhead
- Stack usage: 32 bytes (buffer + locals)

Example:

```
uart_debug_puts("Value: ");
uart_debug_putint(42); // Sends "42"
uart_debug_putint(-2147483648); // Sends "-2147483648"
uart_debug_putc('\n');
```

Here is the call graph for this function:

#### 8.1.5.83 `uart_debug_puts()`

```
void uart_debug_puts (
 const char * str)
```

Transmit a null-terminated string on debug UART (SCI9).

##### Parameters

|    |     |                   |
|----|-----|-------------------|
| in | str | Pointer to string |
|----|-----|-------------------|

Transmit a null-terminated string on debug UART (SCI9).

Transmits a null-terminated string to SCI9 with automatic LF-to-`\r`+LF conversion for terminal compatibility. Enforces a maximum length of `k_uart_max_str_len` (256) characters per NASA Power of 10 Rule 2. Silently returns on NULL pointer to allow safe use in early init.

Algorithm steps:

1. Return immediately if `str` is `nullptr` (defensive, no error return)
2. For each character up to `k_uart_max_str_len`:
  - a. Stop at null terminator
  - b. If LF, send `\r` first
  - c. Send character via [uart\\_debug\\_putc\(\)](#)

##### Precondition

[uart\\_debug\\_init\(\)](#) must have been called successfully  
`str` should point to a null-terminated string in valid memory

## Postcondition

All characters up to null terminator transmitted to SCI9  
Each LF replaced by `\r\n` in the transmitted output

## Note

No return value - errors from `uart_debug_putc()` are silently discarded  
String truncated at `k_uart_max_str_len` (256) characters

## Warning

Only available when `RX_IS_SIMULATOR` is 0 (hardware builds)

## Thread Safety:

Not safe for concurrent access on SCI9 without external mutex.

## Performance:

- Execution time: ~90 us per character @ 115200 baud
- Stack usage: 24 bytes

## Example:

```
uart_debug_puts("Hello, World!\n"); // Sends "Hello, World!\r\n"
uart_debug_puts("[INFO] Boot complete\n");
```

#### 8.1.5.84 uart\_deinit\_channel()

```
rx_err_t uart_deinit_channel (
 const uart_channel_t channel) [nodiscard]
```

Deinitialize SCI channel.

Parameters

|    |         |                    |
|----|---------|--------------------|
| in | channel | SCI channel (0-12) |
|----|---------|--------------------|

### Returns

k\_rx\_ok on success, k\_rx\_err\_invalid\_arg if channel is invalid

### Deinitialize SCI channel.

Disables transmit and receive on the specified SCI channel and marks it as uninitialized. The module clock is left running (safe to re-initialize without re-enabling). After this call the channel may be re-initialized with `uart_init_channel()`.

### Algorithm steps:

1. Validate channel number (0-12)
2. Get SCI register base address
3. Write S\r = 0 to disable TX and RX
4. Clear s\_channel\_initialized[channel]

### Precondition

channel must be in range [0, 12]

Channel should be initialized before deinitializing (safe to call on uninit channel)

### Postcondition

TX and RX disabled (S\r = 0)

s\_channel\_initialized[channel] set to false

### Note

Not thread-safe - call during shutdown, not during normal operation

Module stop clock is NOT re-asserted (peripheral clock left enabled)

### Thread Safety:

Not thread-safe. Do not call while another thread is using the channel.

### Performance:

- Execution time: ~1 us
- Stack usage: 16 bytes

### Example:

```
rx_err_t err = uart_deinit_channel(k_uart_channel_9);
if (err != k_rx_ok) {
 // Handle error (invalid channel)
}
// Channel is now disabled and can be re-initialized
```

#### 8.1.5.85 `uart_getc_channel()`

```
rx_err_t uart_getc_channel (
 const uart_channel_t channel,
 char * data) [nodiscard]
```

Receive a single character from specified channel (non-blocking).

## Parameters

|     |         |                                     |
|-----|---------|-------------------------------------|
| in  | channel | SCI channel (0-12)                  |
| out | data    | Pointer to store received character |

## Returns

k\_rx\_ok on success, k\_rx\_err\_null\_ptr if data is nullptr, k\_rx\_err\_invalid\_arg if channel is invalid, k\_rx\_err\_invalid\_state if channel not initialized, k\_rx\_err\_empty if no data available

Receive a single character from specified channel (non-blocking).

Attempts to read a single byte from the specified SCI channel's receive data register (RDR). This is a non-blocking operation - returns immediately with k\_rx\_err\_empty if no data is available.

## Algorithm steps:

1. Validate data pointer and channel number
2. Check channel initialization state
3. Get SCI register base address
4. Clear any error flags (ORER, FER, PER)
5. Check RDRF flag (Receive Data Register Full)
  - If not set, return k\_rx\_err\_empty immediately
6. Read data byte from RDR register
7. Clear RDRF flag (read SSR, write back with RDRF=0)

## Error flag handling:

- ORER (Overflow Error): Previous data overwritten before read
- FER (Framing Error): Stop bit not detected
- PER (Parity Error): Parity mismatch (not used in 8N1 mode)

## Precondition

Channel must be initialized via [uart\\_init\\_channel\(\)](#)  
data must point to valid memory for single char

## Postcondition

On success, \*data contains received byte  
RDRF flag cleared (ready for next byte)  
Error flags cleared if any were set

#### Note

- Non-blocking - returns immediately if no data
- Clears error flags automatically before read
- Single byte buffer - call frequently to avoid overrun

#### Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

#### Performance:

- Execution time: ~5 us (no wait)
- Stack usage: 16 bytes

#### Example (Polling Loop):

```
char c;
rx_err_t err;

// Poll for incoming data
do {
 err = uart_getc_channel(k_uart_channel_9, &c);
 if (err == k_rx_ok) {
 process_character(c);
 }
} while (err == k_rx_ok); // Continue while data available
```

#### Example (Timeout Loop):

```
char c;
uint32_t timeout = 100000;

while (timeout > 0) {
 rx_err_t err = uart_getc_channel(k_uart_channel_9, &c);
 if (err == k_rx_ok) {
 // Got data
 break;
 }
 timeout--;
}

if (timeout == 0) {
 // No data received within timeout
}
```

#### 8.1.5.87 uart\_putc\_channel()

```

rx_err_t uart_putc_channel (
 const uart_channel_t channel,
 const char data) [nodiscard]

```

Transmit a single character on specified channel.

Parameters

|    |         |                       |
|----|---------|-----------------------|
| in | channel | SCI channel (0-12)    |
| in | data    | Character to transmit |

### Returns

k\_rx\_ok on success, k\_rx\_err\_invalid\_arg if channel is invalid, k\_rx\_err\_invalid\_state if channel not initialized

Transmit a single character on specified channel.

Transmits a single byte on the specified SCI channel. Waits for the transmit data register to become empty (TDRE flag) with timeout protection, then writes the data to TDR. Uses polling mode (no interrupts).

Algorithm steps:

1. Validate channel number (0-12)
2. Check channel is initialized
3. Get SCI register base address
4. Wait for TDRE flag with timeout (k\_uart\_tx\_timeout iterations)
5. Write data byte to TDR register
6. Clear TDRE flag (read SSR, write back with TDRE=0)

Character transmission timing at 115200 baud:

- Start bit: 8.68 us
- 8 data bits: 69.44 us
- Stop bit: 8.68 us
- Total: ~86.8 us per character

### Precondition

Channel must be initialized via [uart\\_init\\_channel\(\)](#)  
UART TX must be enabled (happens during init)

### Postcondition

Character written to TDR and transmission started  
TDRE flag cleared (TDR occupied)

### Note

Blocking call - waits for TDRE flag  
Timeout prevents infinite wait if hardware fails

### Warning

May block for up to ~100ms if TX line is held low

Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

Performance:

- Execution time: ~90 us @ 115200 baud (one character time)
- Stack usage: 16 bytes

Example:

```
// Send single character
rx_err_t err = uart_putc_channel(k_uart_channel_9, 'A');
if (err != k_rx_ok) {
 // Handle error
}

// Send carriage return + line feed
uart_putc_channel(k_uart_channel_9, '\\r');
uart_putc_channel(k_uart_channel_9, '\\n');
```

#### 8.1.5.88 uart\_puts\_channel()

```

rx_err_t uart_puts_channel (
 const uart_channel_t channel,
 const char * str) [nodiscard]

```

Transmit a null-terminated string on specified channel.

Parameters

|    |         |                    |
|----|---------|--------------------|
| in | channel | SCI channel (0-12) |
| in | str     | Pointer to string  |

Returns

k\_rx\_ok on success, k\_rx\_err\_null\_ptr if str is nullptr, k\_rx\_err\_invalid\_arg if channel is invalid, k\_rx\_err\_invalid\_state if channel not initialized

Transmit a null-terminated string on specified channel.

Transmits a null-terminated string with automatic LF to \r+LF conversion for terminal compatibility. Enforces maximum string length (k\_uart\_max\_str\_len = 256) to comply with NASA Power of 10 Rule 2 (bounded loops).

Algorithm steps:

1. Validate string pointer (NULL check)
2. Validate channel number and initialization state
3. For each character up to k\_uart\_max\_str\_len: a. Check for null terminator (success exit) b. If ' ', send '\r' first (\r+LF conversion) c. Transmit character via [uart\\_putc\\_channel\(\)](#) d. Propagate any errors immediately
4. If limit reached without terminator, return k\_rx\_err\_invalid\_size

Newline conversion:

- Input ' ' (LF) -> Output '\r\n' (\r+LF)
- Required for Windows terminals (e.g., PuTTY, TeraTerm)
- Ensures cursor returns to column 0 before line feed

#### Precondition

Channel must be initialized via `uart_init_channel()`  
str must point to null-terminated string in valid memory

#### Postcondition

All characters transmitted including converted newlines  
On error, partial string may have been transmitted

#### Note

Blocking call - waits for each character to transmit  
String length limited to 256 characters for safety

#### Warning

Long strings may take significant time (256 chars ~ 22ms @ 115200)

#### Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

#### Performance:

- Execution time: ~90 us per character @ 115200 baud
- Stack usage: 24 bytes
- Example: 100-char string ~ 9 ms

#### Example:

```
// Simple string
uart_puts_channel(k_uart_channel_9, "Hello, World!\n");
// Output: "Hello, World!\r\n"

// Multiple lines
uart_puts_channel(k_uart_channel_9, "Line 1\nLine 2\nLine 3\n");
// Output: "Line 1\r\nLine 2\r\nLine 3\r\n"

// Error handling
rx_err_t err = uart_puts_channel(k_uart_channel_9, msg);
if (err != k_rx_ok) {
 // Partial transmission may have occurred
}
```

#### 8.1.5.89 uart\_read\_channel()

```

rx_err_t uart_read_channel (
 const uart_channel_t channel,
 uint8_t * data,
 uint16_t length,
 uint16_t * bytes_read) [nodiscard]

```

Read available data from specified channel (non-blocking).

Reads up to length bytes that are currently available.

## Parameters

|     |            |                                     |
|-----|------------|-------------------------------------|
| in  | channel    | SCI channel (0-12)                  |
| out | data       | Pointer to buffer for received data |
| in  | length     | Maximum number of bytes to read     |
| out | bytes_read | Pointer to store actual bytes read  |

## Returns

k\_rx\_ok on success, k\_rx\_err\_null\_ptr if data or bytes\_read is nullptr, k\_rx\_err\_invalid\_arg if channel is invalid, k\_rx\_err\_invalid\_state if channel not initialized

Read available data from specified channel (non-blocking).

Reads up to length bytes from the specified SCI channel using [uart\\_getc\\_channel\(\)](#). Stops immediately when no more data is available (RDRE flag not set) rather than waiting. Actual bytes received is reported via bytes\_read.

Algorithm steps:

1. Validate data and bytes\_read pointers (NULL check)
2. Validate channel number and initialization state
3. Set \*bytes\_read = 0
4. For each slot in [0, length): a. Call [uart\\_getc\\_channel\(\)](#); if k\_rx\_err\_empty, break (done) b. On other error, propagate immediately c. Store byte and increment \*bytes\_read
5. Return k\_rx\_ok (even if zero bytes were read)

## Precondition

Channel must be initialized via [uart\\_init\\_channel\(\)](#)  
data must point to at least length bytes of writable memory

## Postcondition

\*bytes\_read set to actual number of bytes received  
data[0..\*bytes\_read-1] contain the received bytes

## Note

Non-blocking - returns immediately with whatever data is available  
k\_rx\_ok with \*bytes\_read == 0 means no data was available

## Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

Performance:

- Execution time:  $\sim 5$  us per byte received +  $\sim 5$  us when no data
- Stack usage: 24 bytes

Example:

```
uint8_t buf[64];
uint16_t count = 0;
rx_err_t err = uart_read_channel(k_uart_channel_9, buf, sizeof(buf), &count);
if (err == k_rx_ok && count > 0) {
 process_bytes(buf, count);
}
```

#### 8.1.5.90 uart`rx`available()

```

rx_err_t uart_rx_available (
 const uart_channel_t channel,
 bool * available) [nodiscard]

```

Check if receive data is available on channel.

##### Parameters

|     |           |                                      |
|-----|-----------|--------------------------------------|
| in  | channel   | SCI channel (0-12)                   |
| out | available | Pointer to store availability status |

##### Returns

k\_rx\_ok on success, k\_rx\_err\_null\_ptr if available is nullptr, k\_rx\_err\_invalid\_arg if channel is invalid, k\_rx\_err\_invalid\_state if channel not initialized

Check if receive data is available on channel.

Checks the RDRF (Receive Data Register Full) flag in the SSR register of the specified SCI channel. Provides a non-destructive peek at receive availability without consuming any data from the buffer.

Algorithm steps:

1. Validate available pointer (NULL check)
2. Validate channel number and initialization state
3. Get SCI register base address
4. Read SSR and test RDRF bit; store boolean result in \*available

#### Precondition

Channel must be initialized via [uart\\_init\\_channel\(\)](#)  
available must point to valid bool storage

#### Postcondition

\*available reflects current RDRF state  
No data is consumed from the receive buffer

#### Note

Non-destructive - does not read RDR or clear any flags  
RDRF can be set again immediately after reading if UART is receiving

#### Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

#### Performance:

- Execution time: ~2 us
- Stack usage: 16 bytes

#### Example:

```
bool ready = false;
if (uart_rx_available(k_uart_channel_9, &ready) == k_rx_ok && ready) {
 char c;
 uart_getc_channel(k_uart_channel_9, &c);
}
```

#### 8.1.5.91 `uart_write_channel()`

```
rx_err_t uart_write_channel (
 const uart_channel_t channel,
 const uint8_t * data,
 uint16_t length) [nodiscard]
```

Write buffer to specified channel.

## Parameters

|    |         |                          |
|----|---------|--------------------------|
| in | channel | SCI channel (0-12)       |
| in | data    | Pointer to data buffer   |
| in | length  | Number of bytes to write |

## Returns

k\_rx\_ok on success, k\_rx\_err\_null\_ptr if data is nullptr, k\_rx\_err\_invalid\_arg if channel is invalid, k\_rx\_err\_invalid\_state if channel not initialized

Write buffer to specified channel.

Transmits a block of raw bytes on the specified SCI channel using [uart\\_putc\\_channel\(\)](#) for each byte. No LF-to-\r+LF conversion is performed, making this function suitable for binary protocol data.

Algorithm steps:

1. Validate data pointer (NULL check)
2. Validate channel number and initialization state
3. For each byte in [0, length): call [uart\\_putc\\_channel\(\)](#) and propagate errors

## Precondition

Channel must be initialized via [uart\\_init\\_channel\(\)](#)  
data must point to at least length bytes of valid memory

## Postcondition

All length bytes transmitted in order  
On error, partial data may have been transmitted

## Note

Blocking call - waits for each byte to be accepted by TDR  
No newline conversion - use [uart\\_puts\\_channel\(\)](#) for text output

## Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

## Performance:

- Execution time: ~90 us per byte @ 115200 baud
- Stack usage: 24 bytes

Example:

```
const uint8_t frame[] = {0xAA, 0x55, 0x01, 0x02, 0x03};
rx_err_t err = uart_write_channel(k_uart_channel_9, frame, sizeof(frame));
if (err != k_rx_ok) {
 // Handle partial write
}
```

00064 *
00065 * ## Key Design Principles
00066 *
00067 * ### 1. Type Safety (C23 Typed Enums + Struct Wrappers)
00068 * - **Typed enums**: All constants use C23 `uint8_t` syntax for guaranteed size
00069 * - **Struct wrappers**: I2C channel/address use struct wrappers to prevent argument swaps
00070 * - **Compile-time validation**: Invalid types caught at compile time, not runtime
00071 *
00072 * **Example - Type Safety Prevents Bugs**:
00073 * @code{.c}
00074 * // WRONG - Swapped arguments with plain uint8_t
00075 * riic_write(0x48, 0, data, len); // Accidentally swapped channel and address
00076 *
00077 * // CORRECT - Struct wrappers catch this at compile time
00078 * riic_channel_t ch = {.value = 0};
00079 * i2c_device_addr_t addr = {.value = 0x48};
00080 * riic_write(ch, addr, data, len); // Type-checked, no accidental swaps possible
00081 * @endcode
00082 *
00083 * ### 2. Unified Error Handling
00084 * - **Consistent returns**: All functions return `rx_err_t` (except debug helpers)
00085 * - **Comprehensive error codes**: Covers NULL pointers, invalid arguments, timeouts, conflicts
00086 * - **Validation**: All functions validate inputs before hardware access
00087 *
00088 * ### 3. Configuration Structs Over Positional Parameters
00089 * - **Maintainability**: Adding new config options doesn't break API
00090 * - **Clarity**: Named fields > positional parameters
00091 * - **Safety**: Reduces parameter order mistakes
00092 *
00093 * **Example**:
00094 * @code{.c}
00095 * // OLD STYLE (error-prone):
00096 * uart_init(9, 115200, k_port_b_pin_7, k_port_b_pin_6); // Which pin is TX vs RX?
00097 *
00098 * // NEW STYLE (clear and safe):
00099 * uart_channel_config_t config = {
00100 * .channel = k_uart_channel_9,
00101 * .baudrate = 115200,
00102 * .tx_gpio = k_port_b_pin_7,
00103 * .rx_gpio = k_port_b_pin_6
00104 * };
00105 * uart_init_channel(&config); // Self-documenting
00106 * @endcode
00107 *
00108 * ### 4. Zero Dynamic Allocation (NASA Rule 3)
00109 * - All functions use stack-based parameters
00110 * - No malloc/free anywhere in HAL
00111 * - Predictable memory behavior for safety-critical systems
00112 *
00113 * ## Performance Characteristics
00114 *
00115 * ### Function Call Overhead (RX72N @ 240 MHz)
00116 * | Function Category | Cycles | Time | Notes |
00117 * |-----|-----|-----|-----|

```

```

00118 * | GPIO write | ~20 | 83 ns | Direct register access |
00119 * | GPIO read | ~25 | 104 ns | Includes pin validation |
00120 * | UART putc | ~150 | 625 ns | Polling TDRE flag |
00121 * | UART puts (10 chars) | ~1500 | 6.25 us | 150 cycles/char |
00122 * | I2C write (1 byte) | ~24000 | 100 us | 400kHz I2C clock |
00123 * | SPI transfer (1 byte) | ~480 | 2 us | 10 MHz SPI clock |
00124 * | ADC read | ~7200 | 30 us | 12-bit conversion + validation |
00125
00126 * ### Memory Footprint
00127 * | Component | Flash | RAM | Stack (max) |
00128 * |-----|-----|-----|-----|
00129 * | GPIO drivers | ~2 KB | 16 bytes (state) | 32 bytes |
00130 * | UART drivers | ~3 KB | 128 bytes (buffers) | 48 bytes |
00131 * | I2C drivers | ~4 KB | 64 bytes (state) | 64 bytes |
00132 * | SPI drivers | ~5 KB | 96 bytes (state) | 64 bytes |
00133 * | ADC drivers | ~2 KB | 32 bytes (state) | 32 bytes |
00134 * | **Total HAL** | ~16 KB | ~336 bytes | ~240 bytes |
00135
00136 * ## Thread Safety
00137 * - **NOT thread-safe**: Hardware registers are not protected by mutexes
00138 * - **Single-threaded access**: Each peripheral should be accessed from one thread only
00139 * - **RTOS integration**: Use ThreadX mutexes if multi-threaded access needed
00140 * - **Interrupt safety**: All HAL functions disable interrupts during critical sections
00141
00142 * ## Initialization Sequence
00143
00144 * Recommended initialization order for STAR motor controller:
00145 * @code{.c}
00146 void hardware_init(void) {
00147 // 1. Debug UART (for early logging)
00148 uart_debug_init();
00149 rx_log_info("INIT", "Starting hardware initialization");
00150
00151 // 2. System timer (for ThreadX tick)
00152 timer_init();
00153
00154 // 3. GPIO (for motor control signals)
00155 gpio_set_output(k_port_c_pin_0); // Motor enable
00156 gpio_set_output(k_port_c_pin_1); // Direction
00157
00158 // 4. SPI controller (for sensors; DRV8263H uses PWM+GPIO, not SPI)
00159 rspi_controller_config_t spi_cfg = {
00160 .spi_mode = k_rspi_mode_0,
00161 .freq_hz = k_rspi_freq_1mhz,
00162 .cs = k_port_c_pin_4
00163 };
00164 rspi_init_controller(k_rspi_channel_1, &spi_cfg);
00165
00166 // 5. SPI peripheral (for RPi5 communication)
00167 rspi_config_t rpi_cfg = {
00168 .spi_mode = k_rspi_mode_0,
00169 .use_16bit = false
00170 };
00171 rspi_init_peripheral(k_rspi_channel_0, &rpi_cfg);
00172
00173 // 6. ADC (for motor current sensing on AN007/P47)
00174 adc_init(k_adc_unit_0, k_adc_channel_7, k_adc_resolution_12bit);
00175
00176 // 7. I2C (for IMU sensor)
00177 riic_init((riic_channel_t){.value = 0}, 400000);
00178
00179 rx_log_info("INIT", "Hardware initialization complete");
00180 }
00181 * @endcode
00182
00183 * ## Pin Assignments (From Project Schematic)
00184
00185 * See `docs/sections/03_hardware_pinout.tex` for complete pinout documentation.
00186
00187 * **Critical Signals**:
00188 * | Signal | Pin | Peripheral | Purpose |
00189 * |-----|-----|-----|-----|
00190 * | SPI0_CIPO | P30 | RSPI0 | RPi5 <- RX72N (peripheral mode) |
00191 * | SPI0_COPI | P31 | RSPI0 | RPi5 -> RX72N |
00192 * | SPI0_CLK | P32 | RSPI0 | RPi5 clock |
00193 * | SPI0_CS | P33 | GPIO | RPi5 chip select |
00194 * | SPI1_CIPO | PC5 | RSPI1 | Not used (RSPI1 controller mode) |
00195 * | SPI1_COPI | PC6 | RSPI1 | Not used (RSPI1 controller mode) |
00196 * | SPI1_CLK | PC7 | RSPI1 | Not used (RSPI1 clock) |
00197 * | UART_TX | PB7 | SCI9 | Debug output (CY7C65213) |
00198 * | UART_RX | PB6 | SCI9 | Debug input |
00199
00200 * ## Dependencies
00201 * - `rx_err.h` - Error code definitions
00202 * - `rx_check.h` - Validation macros
00203 * - `rx_log.h` - Logging infrastructure
00204 * - `rx_port_constants.h` - Port/pin definitions

```

```

00205 * - `rx_bus_types.h` - Bus enumeration types
00206 * - `rx72n_regs.h` - Hardware register definitions (internal)
00207 *
00208 * @par NASA Power of 10 Compliance:
00209 * - **Rule 1 [YES]** No goto, setjmp, recursion (pure validation + register access)
00210 * - **Rule 2 [YES]** All loops bounded (timeout loops use compile-time max iterations)
00211 * - **Rule 3 [YES]** No dynamic allocation (all stack-based or static configuration)
00212 * - **Rule 4 [YES]** All functions <60 lines (HAL functions are typically 20-40 lines)
00213 * - **Rule 5 [YES]** Minimum 2 validations per function (NULL checks + range validation)
00214 * - **Rule 6 [YES]** Data at smallest scope (loop counters, temporary variables)
00215 * - **Rule 7 [YES]** All returns validated (rx_err_t checked at every call site)
00216 * - **Rule 8 [YES]** C23 typed enums for constants, minimal preprocessor use
00217 * - **Rule 9 [YES]** Single-level dereferencing (pointer parameters for output values)
00218 * - **Rule 10 [YES]** Compiles with -Wall -Wextra -Werror
00219 *
00220 * @par SOLID Principles:
00221 * - **S (Single Responsibility)** Each peripheral has dedicated functions (GPIO, UART, SPI, I2C, ADC)
00222 * - **O (Open/Closed)** Config structs allow extension without modifying function signatures
00223 * - **L (Liskov Substitution)** All HAL functions return rx_err_t with consistent semantics
00224 * - **I (Interface Segregation)** Separate controller/peripheral SPI APIs, debug UART wrappers
00225 * - **D (Dependency Inversion)** Depends on abstract rx_err_t, rx_log, not concrete implementations
00226 *
00227 * @par Module Dependencies:
00228 * ```
00229 * hardware.h
00230 * +--> rx_err.h (error codes)
00231 * +--> rx_check.h (validation macros)
00232 * +--> rx_log.h (logging)
00233 * +--> rx_port_constants.h (port/pin enums)
00234 * +--> rx_bus_types.h (ADC resolution enums)
00235 * +--> [internal] rx72n_regs.h (register definitions)
00236 *
00237 * Used by:
00238 * +--> Motor control (rx_motor_control.c)
00239 * +--> USB communication (rx_usb.c)
00240 * +--> Protocol handling (rx_comm_manager.c)
00241 * +--> Application tasks (comm, motor, sensors)
00242 * ```

=====
00279 */
00280 /**
00281 * @brief Configure GPIO pin as digital output
00282 *
00283 * @details
00284 * Configures the specified GPIO pin as a digital output with push-pull drive.
00285 * Performs full hardware initialization including port direction register (PDR),
00286 * port mode register (PMR), and open-drain control (ODR). Validates pin assignment
00287 * and checks for peripheral conflicts.
00288 *
00289 */

```

```

00290 * ## Algorithm
00291 * 1. Validate pin parameter (port exists, pin number valid)
00292 * 2. Check pin is not already reserved by another peripheral
00293 * 3. Unlock port write protection (PWPR register)
00294 * 4. Set PMR bit to 0 (GPIO mode, not peripheral function)
00295 * 5. Set PDR bit to 1 (output direction)
00296 * 6. Ensure ODR is 0 (push-pull, not open-drain)
00297 * 7. Lock port write protection
00298 * 8. Mark pin as reserved in allocation tracker
00299 *
00300 * ## Performance
00301 * - **Cycles**: ~120 @ 240 MHz
00302 * - **Time**: ~500 ns
00303 * - **Stack**: 8 bytes (pin validation, temporary registers)
00304 *
00305 * @param[in] pin GPIO pin identifier from rx_port_constants.h
00306 * - Type: rx_port_pin_t (C23 typed enum)
00307 * - Format: k_port_X_pin_Y (X = A-N, Y = 0-7)
00308 * - Example: k_port_c_pin_0 (Port C, Pin 0)
00309 * - Range: All valid combinations defined in rx_port_constants.h
00310 *
00311 * @return rx_err_t Error code indicating success or failure
00312 * @retval k_rx_ok Pin successfully configured as output
00313 * @retval k_rx_err_gpio_invalid_port Port letter out of range (not A-N)
00314 * @retval k_rx_err_gpio_invalid_pin Pin number out of range (not 0-7)
00315 * @retval k_rx_err_gpio_conflict Pin already reserved by UART, SPI, I2C, or other peripheral
00316 *
00317 * @pre Pin must not be currently in use by another peripheral
00318 * @post Pin configured as push-pull output, initial state undefined (use gpio_write_* to set level)
00319 * @post Pin marked as reserved in internal allocation tracker
00320 *
00321 * @note **Thread Safety**: NOT thread-safe. Do not call concurrently from multiple threads.
00322 * @note **Initial State**: Output level is undefined after configuration. Call gpio_write_high() or gpio_write_low() to
00323 * set initial state.
00324 * @note **Peripheral Conflicts**: Automatically detects conflicts with UART, SPI, I2C pin assignments.
00325 *
00326 * @warning Changing pin direction while peripheral is active may cause undefined behavior.
00327 *
00328 * @par Example: Motor Enable Pin
00329 * @code{.c}
00330 * #include "hardware.h"
00331 *
00332 * void motor_init(void) {
00333 * // Configure motor enable pin as output
00334 * rx_err_t err = gpio_set_output(k_port_c_pin_0);
00335 * if (err != k_rx_ok) {
00336 * rx_log_error_val("MOTOR", "Failed to configure enable pin", err);
00337 * return;
00338 * }
00339 *
00340 * // Set initial state (motors disabled)
00341 * gpio_write_low(k_port_c_pin_0);
00342 * rx_log_info("MOTOR", "Enable pin configured");
00343 * }
00344 * @endcode
00345 *
00346 * @par Example: Multiple GPIO Outputs
00347 * @code{.c}
00348 * void configure_leds(void) {
00349 * const rx_port_pin_t led_pins[] = {
00350 * k_port_e_pin_5, // LED1
00351 * k_port_e_pin_6, // LED2
00352 * k_port_e_pin_7 // LED3
00353 * };
00354 *
00355 * for (uint8_t i = 0; i < 3; i++) {
00356 * rx_err_t err = gpio_set_output(led_pins[i]);
00357 * if (err != k_rx_ok) {
00358 * rx_log_error_hex("GPIO", "LED init failed", i, 2);
00359 * } else {
00360 * gpio_write_low(led_pins[i]); // LEDs off initially
00361 * }
00362 * }
00363 * }
00364 * @endcode
00365 *
00366 * @par Example: Error Handling
00367 * @code{.c}
00368 * rx_err_t setup_motor_control_pins(void) {
00369 * // Try to configure direction pin
00370 * rx_err_t err = gpio_set_output(k_port_c_pin_1);
00371 * if (err == k_rx_err_gpio_conflict) {
00372 * rx_log_error("MOTOR", "Pin conflict - already used by SPI?");
00373 * return err;
00374 * } else if (err != k_rx_ok) {
00375 * rx_log_error_val("MOTOR", "Unexpected error", err);
00376 * return err;
00377 * }
00378 * }

```

```

00376 * }

00443 * @see gpio_read() Read pin logic level
00444 *
00445 * @since Version 1.0.0
00446 */
00447 [[nodiscard]] rx_err_t gpio_set_input(rx_port_pin_t pin);
00448
00449 /**
00450 * @brief Set GPIO output pin to logic high (VDD)
00451 *
00452 * @details
00453 * Drives the specified GPIO pin to logic high by setting the corresponding bit
00454 * in the Port Output Data Register (PODR). The pin must have been previously
00455 * configured as output via gpio_set_output(). Writing to an input pin has no
00456 * effect on the physical pin state.
00457 *
00458 * ## Algorithm
00459 * 1. Validate pin parameter (port exists, pin number valid)
00460 * 2. Extract port letter and pin number from rx_port_pin_t
00461 * 3. Set corresponding bit in PODR register (atomic read-modify-write)
00462 *

```

```

00463 * @param[in] pin GPIO pin identifier from rx_port_constants.h
00464 * - Type: rx_port_pin_t (C23 typed enum)
00465 * - Format: k_port_X_pin_Y (X = A-N, Y = 0-7)
00466 * - Must be configured as output via gpio_set_output()
00467 *
00468 * @return rx_err_t Error code indicating success or failure
00469 * @retval k_rx_ok Pin successfully driven high
00470 * @retval k_rx_err_gpio_invalid_port Port letter out of range (not A-N)
00471 * @retval k_rx_err_gpio_invalid_pin Pin number out of range (not 0-7)
00472 *
00473 * @pre Pin must be configured as output via gpio_set_output()
00474 * @pre Pin port and number must be within valid hardware range
00475 * @post Pin output level is logic high (VDD, typically 3.3V)
00476 * @post PODR register bit for the pin is set to 1
00477 *
00478 * @note **Thread Safety**: NOT thread-safe. Concurrent writes to pins on the same port may
00479 * cause read-modify-write races on the PODR register.
00480 *
00481 * @par Example: Enable Motor
00482 * @code{.c}
00483 * // Enable motor driver (active high)
00484 * rx_err_t err = gpio_write_high(k_port_c_pin_0);
00485 * if (err != k_rx_ok) {
00486 * rx_log_error_val("MOTOR", "Failed to enable motor", err);
00487 * }
00488 * @endcode

00564 * - Must be configured as output via gpio_set_output()
00565 *
00566 * @return rx_err_t Error code indicating success or failure
00567 * @retval k_rx_ok Pin successfully toggled
00568 * @retval k_rx_err_gpio_invalid_port Port letter out of range (not A-N)
00569 * @retval k_rx_err_gpio_invalid_pin Pin number out of range (not 0-7)
00570 *
00571 * @pre Pin must be configured as output via gpio_set_output()
00572 * @pre Pin port and number must be within valid hardware range
00573 * @post Pin output level is inverted from its previous state
00574 * @post PODR register bit for the pin is toggled
00575 *
00576 * @note **Thread Safety**: NOT thread-safe. Concurrent toggles or writes to pins on the same
00577 * port may cause read-modify-write races on the PODR register.
00578 *
00579 * @par Example: LED Heartbeat
00580 * @code{.c}
00581 * // Toggle heartbeat LED every 500 ms
00582 * void heartbeat_task(void) {
00583 * gpio_set_output(k_port_e_pin_5);
00584 * while (1) {
00585 * gpio_toggle(k_port_e_pin_5);
00586 * tx_thread_sleep(50); // 500 ms at 100 Hz tick
00587 * }
00588 * }
00589 * @endcode
00590 *
00591 * @see gpio_write_high() Set output pin to logic high
00592 * @see gpio_write_low() Set output pin to logic low
00593 * @see gpio_set_output() Configure pin as output first
00594 *
00595 * @since Version 1.0.0
00596 */
00597 [[nodiscard]] rx_err_t gpio_toggle(rx_port_pin_t pin);
00598
00599 /**
00600 * @brief Read current logic level of GPIO pin
00601 *
00602 * @details
00603 * Reads the current logic level from the specified GPIO pin's Port Input Data Register (PIDR).
00604 * Works for both input and output pins. For output pins, reads back the actual pin state
00605 * (not the output register), which may differ if external circuitry pulls the pin.
00606 *
00607 * ## Algorithm
00608 * 1. Validate pin parameter (port exists, pin number valid)
00609 * 2. Validate value pointer (NULL check)
00610 * 3. Extract port letter and pin number from rx_port_pin_t
00611 * 4. Read PIDR register for the specified port
00612 * 5. Extract bit corresponding to pin number
00613 * 6. Store result (true if bit=1, false if bit=0) in value pointer
00614 *
00615 * ## Performance
00616 * - **Cycles**: ~25 @ 240 MHz
00617 * - **Time**: ~104 ns
00618 * - **Stack**: 8 bytes (pin extraction, register read)
00619 *
00620 * @param[in] pin GPIO pin identifier from rx_port_constants.h
00621 * - Type: rx_port_pin_t (C23 typed enum)
00622 * - Format: k_port_X_pin_Y (X = A-N, Y = 0-7)
00623 * - Can be input or output pin
00624 * @param[out] value Pointer to boolean for storing pin state
00625 * - Must point to valid bool variable
00626 * - Set to true if pin reads logic high (VDD)
00627 * - Set to false if pin reads logic low (GND)
00628 * - Unchanged if function returns error
00629 *
00630 * @return rx_err_t Error code indicating success or failure
00631 * @retval k_rx_ok Pin level successfully read and stored in *value
00632 * @retval k_rx_err_gpio_invalid_port Port letter out of range (not A-N)
00633 * @retval k_rx_err_gpio_invalid_pin Pin number out of range (not 0-7)
00634 * @retval k_rx_err_null_ptr value pointer is nullptr
00635 *
00636 * @pre value pointer must be valid (not nullptr)

```

```

00637 * @post *value contains current pin state if function succeeds
00638 * @post *value unchanged if function returns error
00639 *
00640 * @note **Thread Safety**: NOT thread-safe. Reading PIDR register is atomic but value pointer access is not protected.
00641 * @note **Output Pins**: For output pins, this reads the actual pin level (PIDR), not the output register (PODR). This
 detects external pull-up/pull-down or short circuits.
00642 * @note **Input Pins**: Ensure pin is configured as input via gpio_set_input() before reading for sensor/button inputs.
00643 *
00644 * @par Example: Reading Button State
00645 * @code{.c}
00646 * #include "hardware.h"
00647 *
00648 * void check_button(void) {
00649 * // Button connected to Port E Pin 5 (active low with pull-up)
00650 * bool button_state;
00651 * rx_err_t err = gpio_read(k_port_e_pin_5, &button_state);
00652 *
00653 * if (err != k_rx_ok) {
00654 * rx_log_error_val("BUTTON", "Failed to read button", err);
00655 * return;
00656 * }
00657 *
00658 * if (!button_state) { // Active low (button pressed)
00659 * rx_log_info("BUTTON", "Button pressed");
00660 * handle_button_press();
00661 * }
00662 * }
00663 * @endcode
00664 *
00665 * @par Example: Verifying Output State
00666 * @code{.c}
00667 * // Set motor enable high
00668 * gpio_write_high(k_port_c_pin_0);
00669 *
00670 * // Verify pin actually went high (detects short circuit)
00671 * bool actual_state;
00672 * gpio_read(k_port_c_pin_0, &actual_state);
00673 * if (!actual_state) {
00674 * rx_log_error("MOTOR", "Enable pin stuck low - possible short circuit");
00675 * emergency_shutdown();
00676 * }
00677 * @endcode
00678 *
00679 * @par Example: Polling Multiple Inputs

00859 * @enum adc_unit_t
00860 * @brief ADC unit enumeration with type safety for 12-bit SAR ADC modules
00861 *
00862 * @details
00863 * Identifies which of the two independent 12-bit successive approximation ADC units (S12AD)
00864 * on the RX72N to use. Each unit has separate channels, registers, and conversion control.
00865 * Using a typed enum prevents accidental swapping of unit and channel parameters.
00866 *
00867 * ## Hardware Specifications
00868 * | Unit | Base Address | Channels Available | Max Sample Rate |
00869 * |-----|-----|-----|-----|
00870 * | S12AD0 | 0x00089000 | 8 (AN000-AN007) | 1 Msps |
00871 * | S12AD1 | 0x00089100 | 21 (AN100-AN120) | 1 Msps |
00872 *
00873 * ## STAR Project Usage (144-pin LQFP)
00874 * | Unit | Channel | Pin | Signal | Purpose |
00875 * |-----|-----|-----|-----|-----|
00876 * | k_adc_unit_0 | k_adc_channel_7 | P47 | MOTOR_I0 | Motor 0 current sense (DRV8263H IPROPI) |
00877 * | k_adc_unit_0 | k_adc_channel_6 | P46 | MOTOR_I1 | Motor 1 current sense (DRV8263H IPROPI) |
00878 * | k_adc_unit_0 | k_adc_channel_5 | P45 | MOTOR_I2 | Motor 2 current sense |
00879 * | k_adc_unit_0 | k_adc_channel_4 | P44 | MOTOR_I3 | Motor 3 current sense |
00880 *
00881 * ## Type Safety Benefit
00882 * @code{.c}
00883 * // WRONG - Easy to swap unit and channel with plain uint8_t
00884 * adc_read(0, 1, &value); // Is 0 the unit or channel?
00885 *
00886 * // CORRECT - Typed enums make intent clear
00887 * adc_read(k_adc_unit_0, k_adc_channel_1, &value); // Unambiguous
00888 * @endcode
00889 *
00890 * @par Underlying Type: uint8_t (C23 typed enum)
00891 * - **Range**: 0-1 (only 2 units on RX72N)
00892 * - **Size**: 1 byte

```

```

00893 * - **Rationale**: Smallest type sufficient, explicit size guarantees ABI stability
00894 *
00895 * @see adc_channel_t Channel enumeration
00896 * @see adc_resolution_t Resolution configuration
00897 * @see adc_init() ADC initialization function
00898 */

=====
01016 * RIIC (I2C) Functions
01017 *
=====
01018 */
01019
01020 /**
01021 * @struct riic_channel_t
01022 * @brief RIIC (I2C) channel wrapper providing strong type safety
01023 *
01024 * @details
01025 * Wraps RIIC channel number in a struct to prevent accidental argument swaps with
01026 * I2C device addresses. This is a stronger type safety mechanism than simple
01027 * typedefs because structs cannot be implicitly converted.
01028 *
01029 * ### Design Rationale: Struct Wrapper vs. Typedef
01030 *
01031 * **Why struct wrapper instead of simple typedef?**
01032 *
01033 * I2C functions have multiple `uint8_t` parameters that are easily confused:
01034 * - Channel number (0-2)
01035 * - Device address (0x00-0x7F)
01036 * - Register address (0x00-0xFF)
01037 * - Data bytes (0x00-0xFF)
01038 *
01039 * ### Problem with Simple Typedefs
01040 * @code{.c}
01041 * typedef uint8_t riic_channel_t; // Simple typedef
01042 * typedef uint8_t i2c_device_addr_t; // Simple typedef
01043 *
01044 * riic_channel_t ch = 0;
01045 * i2c_device_addr_t addr = 0x48;
01046 *
01047 * // PROBLEM: Arguments can be swapped without compiler error!
01048 * riic_write(addr, ch, data, len); // Compiles! Wrong order, but types are compatible
01049 * @endcode
01050 *
01051 * ### Solution with Struct Wrappers
01052 * @code{.c}
01053 * typedef struct { uint8_t value; } riic_channel_t; // Struct wrapper
01054 * typedef struct { uint8_t value; } i2c_device_addr_t; // Struct wrapper
01055 *
01056 * riic_channel_t ch = {.value = 0};
01057 * i2c_device_addr_t addr = {.value = 0x48};
01058 *
01059 * // CORRECT: Compiler catches swapped arguments!
01060 * riic_write(addr, ch, data, len); // Compile error: type mismatch!
01061 * riic_write(ch, addr, data, len); // Correct order, compiles successfully
01062 * @endcode
01063 *
01064 * ## Comparison: ADC vs. I2C Type Safety

```

```

01065 *
01066 * | Peripheral | Type Safety Mechanism | Rationale |
01067 * |-----|-----|-----|
01068 * | **ADC** | Simple typed enums | Parameters are distinct (unit vs channel vs resolution bits) |
01069 * | **I2C** | Struct wrappers | Multiple uint8_t parameters easily confused |
01070 * | **SPI** | Simple typed enums | Mode, channel, frequency are distinct types |
01071 * | **UART** | Simple typed enums | Channel and baudrate are distinct types |
01072 *
01073 * ADC: `adc_read(k_adc_unit_0, k_adc_channel_1, &value)` -> Different types prevent swaps
01074 * I2C: `riic_write({.value = 0}, {.value = 0x48}, data, len)` -> Struct wrappers prevent swaps
01075 *
01076 * ## RX72N RIIC Hardware
01077 * - **Channels Available**: 3 (RIIC0, RIIC1, RIIC2)
01078 * - **Speeds**: 100 kHz (standard), 400 kHz (fast), 1 MHz (fast-plus)
01079 * - **Addressing**: 7-bit (0x00-0x7F) or 10-bit (not used in STAR project)
01080 *
01081 * ## STAR Project Usage
01082 * | Channel | SCL Pin | SDA Pin | Device | Address | Purpose |
01083 * |-----|-----|-----|-----|-----|-----|
01084 * | 0 | P16 | P17 | IMU (MPU6050) | 0x68 | Orientation sensing |
01085 * | 1 | P54 | P55 | Reserved | - | Future expansion |
01086 * | 2 | P52 | P53 | Reserved | - | Future expansion |
01087 *
01088 * ## Usage Example
01089 * @code{.c}
01090 * #include "hardware.h"
01091 *
01092 * void imu_init(void) {
01093 * // Initialize I2C channel 0 at 400 kHz (fast mode)
01094 * riic_channel_t ch = {.value = 0};
01095 * riic_init(ch, 400000);
01096 *
01097 * // MPU6050 IMU device address
01098 * i2c_device_addr_t imu_addr = {.value = 0x68};
01099 *
01100 * // Write to WHO_AM_I register (0x75) to verify device
01101 * uint8_t reg_addr = 0x75;
01102 * uint8_t who_am_i;
01103 * riic_write_read(ch, imu_addr, ®_addr, 1, &who_am_i, 1);
01104 *
01105 * if (who_am_i == 0x68) {
01106 * rx_log_info("IMU", "MPU6050 detected");
01107 * }
01108 * }
01109 * @endcode
01110 *
01111 * @par Example: Compiler Catches Mistakes
01112 * @code{.c}
01113 * riic_channel_t ch = {.value = 0};
01114 * i2c_device_addr_t addr = {.value = 0x48};
01115 * uint8_t data[] = {0x01, 0x02};
01116 *
01117 * // WRONG - Arguments swapped (compiler error!)
01118 * riic_write(addr, ch, data, 2);
01119 * // Error: cannot convert 'i2c_device_addr_t' to 'riic_channel_t'
01120 *
01121 * // CORRECT - Proper order
01122 * riic_write(ch, addr, data, 2); // Compiles successfully
01123 * @endcode
01124 *
01125 * @see i2c_device_addr_t I2C device address wrapper
01126 * @see riic_init() Initialize I2C channel
01127 * @see riic_write() Write data to I2C device
01128 * @see riic_read() Read data from I2C device
01129 * @see riic_write_read() Combined write-then-read transaction
01130 */
01131 typedef struct {
01132 uint8_t value; /**< RIIC channel number (0-2). Use {.value = N} initialization. */
01133 } riic_channel_t;
01134
01135 /**
01136 * @struct i2c_device_addr_t
01137 * @brief I2C device address wrapper providing strong type safety
01138 *
01139 * @details
01140 * Wraps 7-bit I2C device address in a struct to prevent accidental swaps with
01141 * channel numbers or register addresses. Part of the type safety system that
01142 * uses struct wrappers to catch parameter ordering mistakes at compile time.
01143 *
01144 * ## I2C Addressing
01145 * - **7-bit addressing**: Standard mode used in STAR project
01146 * - **Valid range**: 0x08-0x77 (0x00-0x07 and 0x78-0x7F reserved)
01147 * - **Reserved addresses**:
01148 * - 0x00: General call
01149 * - 0x01-0x07: CBUS, different bus formats
01150 * - 0x78-0x7F: 10-bit addressing, reserved
01151 *

```

```

01152 * ## Common Device Addresses
01153 * | Device | Address | Alt Address | Configurable |
01154 * |-----|-----|-----|-----|
01155 * | MPU6050 (IMU) | 0x68 | 0x69 | Via AD0 pin |
01156 * | BMP280 (Pressure) | 0x76 | 0x77 | Via SDO pin |
01157 * | ADS1115 (ADC) | 0x48-0x4B | - | Via ADDR pin |
01158 * | PCA9685 (PWM) | 0x40-0x7F | - | Via A0-A5 pins |
01159 * | EEPROM (24C series) | 0x50-0x57 | - | Via A0-A2 pins |
01160 *
01161 * ## Address Format on Bus
01162 * The 7-bit address is shifted left by 1 bit and combined with R/W bit:
01163 * ...
01164 * [A6 A5 A4 A3 A2 A1 A0 R/W]
01165 * ____7-bit address____/ _ 0=Write, 1=Read
01166 * ...
01167 * **Note**: HAL automatically handles this shifting. Always provide 7-bit address.
01168 *
01169 * ## STAR Project Devices
01170 * | Device | Address | Channel | Purpose |
01171 * |-----|-----|-----|-----|
01172 * | MPU6050 IMU | 0x68 | RIIC0 | 6-axis motion tracking |
01173 * | Future sensor 1 | TBD | RIIC1 | Expansion |
01174 * | Future sensor 2 | TBD | RIIC2 | Expansion |
01175 *
01176 * ## Usage Example
01177 * @code{.c}
01178 * // MPU6050 IMU on RIIC0
01179 * riic_channel_t ch = {.value = 0};
01180 * i2c_device_addr_t imu_addr = {.value = 0x68};
01181 *
01182 * // Read power management register (0x6B)
01183 * uint8_t pwr_mgmt_reg = 0x6B;
01184 * uint8_t pwr_mgmt_val;
01185 *
01186 * riic_write_read(ch, imu_addr, &pwr_mgmt_reg, 1, &pwr_mgmt_val, 1);
01187 * rx_log_info_hex("IMU", "Power management", pwr_mgmt_val, 2);
01188 * @endcode
01189 *
01190 * @par Example: Multi-Device Bus
01191 * @code{.c}
01192 * // Multiple devices on same I2C bus
01193 * riic_channel_t ch = {.value = 0};
01194 *
01195 * i2c_device_addr_t imu_addr = {.value = 0x68}; // MPU6050
01196 * i2c_device_addr_t baro_addr = {.value = 0x76}; // BMP280
01197 * i2c_device_addr_t adc_addr = {.value = 0x48}; // ADS1115
01198 *
01199 * // Read from different devices on same bus
01200 * uint8_t imu_data[6];
01201 * riic_read(ch, imu_addr, imu_data, 6);
01202 *
01203 * uint8_t baro_data[3];
01204 * riic_read(ch, baro_addr, baro_data, 3);
01205 *
01206 * uint8_t adc_data[2];
01207 * riic_read(ch, adc_addr, adc_data, 2);
01208 * @endcode
01209 *
01210 * @see riic_channel_t RIIC channel wrapper
01211 * @see riic_write() Write data to I2C device
01212 * @see riic_read() Read data from I2C device
01213 * @see riic_write_read() Register read pattern (write reg addr, then read)
01214 */
01215 typedef struct {
01216 uint8_t value; /** < 7-bit I2C device address (0x08-0x77). Use {.value = 0xNN} initialization. */
01217 } i2c_device_addr_t;
01218

01220 * @brief Initialize RIIC channel for I2C controller communication
01221 *
01222 * @details
01223 * Configures the specified RIIC peripheral channel for I2C controller mode at the
01224 * requested clock frequency. Performs full hardware initialization including module
01225 * stop release, pin function selection (SCL/SDA via MPC), internal reset sequence,
01226 * bit rate register (BRH/BRL) calculation from PCLKB, and interrupt configuration.
01227 *
01228 * ## Algorithm
01229 * 1. Validate channel number (0-2) and frequency
01230 * 2. Release RIIC module from module stop (MSTPCRB)
01231 * 3. Assert internal reset (ICCR1.IICRST = 1)
01232 * 4. Configure SCL/SDA pins via MPC register
01233 * 5. Set bit rate registers (BRH/BRL) from PCLKB and frequency_hz
01234 * 6. Configure noise filter, timeout detection
01235 * 7. Release internal reset (ICCR1.IICRST = 0)
01236 * 8. Enable I2C bus (ICCR1.ICE = 1)
01237 *
01238 * ## Supported Frequencies

```

```

01239 * | Frequency | Mode | BRL/BRH | Max Bus Length |
01240 * |-----|-----|-----|-----|
01241 * | 100000 Hz | Standard | Auto-calculated | 1 m |
01242 * | 400000 Hz | Fast | Auto-calculated | 0.3 m |
01243 * | 1000000 Hz | Fast-plus | Auto-calculated | 0.1 m |
01244 *
01245 * @param[in] channel RIIC channel wrapper
01246 * - channel.value range: 0-2
01247 * - Use {.value = N} designated initializer
01248 * @param[in] frequency_hz I2C clock frequency in Hz
01249 * - Valid values: 100000, 400000, 1000000

01671 * RSPI (SPI) Functions - Peripheral Mode
01672 *
=====
01673 */
01674
01675 /**
01676 * @enum rspi_mode_t
01677 * @brief SPI mode enumeration defining clock polarity (CPOL) and phase (CPHA) combinations
01678 *
01679 * @details
01680 * Defines the four standard SPI modes based on clock polarity and phase settings.
01681 * These modes determine when data is sampled relative to the clock edge and what
01682 * the idle state of the clock line is.
01683 *
01684 * ## SPI Mode Definitions
01685 * | Mode | CPOL | CPHA | Clock Idle | Data Sampled | Data Shifted | Common Devices |
01686 * |-----|-----|-----|-----|-----|-----|-----|
01687 * | 0 | 0 | 0 | Low | Rising edge | Falling edge | RPi5, most sensors |
01688 * | 1 | 0 | 1 | Low | Falling edge | Rising edge | SD cards |
01689 * | 2 | 1 | 0 | High | Falling edge | Rising edge | Rare |
01690 * | 3 | 1 | 1 | High | Rising edge | Falling edge | Rare |
01691 *
01692 * ## STAR Project Usage
01693 * | Peripheral | Mode | Rationale |
01694 * |-----|-----|-----|
01695 * | RPi5 (RSPI0 peripheral) | Mode 0 | Linux spidev default, maximum compatibility |
01696 * | RSPI1 controller (not used) | TBD | RSPI1 not used in current design |
01697 *
01698 * ## Clock Polarity (CPOL)
01699 * - **CPOL=0**: Clock idle state is low (GND). Clock starts low, pulses high.
01700 * - **CPOL=1**: Clock idle state is high (VDD). Clock starts high, pulses low.
01701 *
01702 * ## Clock Phase (CPHA)
01703 * - **CPHA=0**: Data sampled on leading clock edge, shifted on trailing edge.
01704 * - **CPHA=1**: Data shifted on leading clock edge, sampled on trailing edge.
01705 *
01706 * ## Timing Diagrams
01707 *
01708 * ### Mode 0 (CPOL=0, CPHA=0) - Most Common
01709 * ```
01710 * CLK: ____/---____/---____
01711 * COPI: ===[D0]===[D1]===
01712 * CIPO: ===[D0]===[D1]===
01713 * ^ Sample ^ Sample
01714 * ```
01715 *
01716 * ### Mode 3 (CPOL=1, CPHA=1)
01717 * ```
01718 * CLK: ---____/---____/---
01719 * COPI: ===[D0]===[D1]===
01720 * CIPO: ===[D0]===[D1]===
01721 * ^ Sample ^ Sample
01722 * ```
01723 *
01724 * ## Selection Guidelines
01725 * 1. **Check device datasheet**: Most devices specify preferred mode
01726 * 2. **Mode 0 default**: Use Mode 0 if device supports multiple modes
01727 * 3. **Controller/Peripheral match**: Both sides must use same mode
01728 * 4. **Avoid Modes 1 and 2**: Less common, higher chance of incompatibility
01729 *
01730 * ## Hardware Configuration
01731 * - **SPCR.CPOL bit**: Set for CPOL=1, clear for CPOL=0
01732 * - **SPCR.CPHA bit**: Set for CPHA=1, clear for CPHA=0
01733 * - **Both configurable**: HAL automatically sets registers based on mode
01734 *
01735 * ## Usage Example
01736 * @code{.c}
01737 * // RPi5 communication (peripheral mode, Mode 0)
01738 * rspi_config_t rpi_cfg = {
01739 * .spi_mode = k_rspi_mode_0, // CPOL=0, CPHA=0
01740 * .use_16bit = false
01741 * };
01742 * rspi_init_peripheral(k_rspi_channel_0, &rpi_cfg);
01743 *
01744 * // External sensor communication (controller mode, Mode 0)

01844 * @brief Initialize RSPI channel in peripheral mode for RPi5 communication
01845 *
01846 * @details
01847 * Configures the specified RSPI channel as an SPI peripheral device.
01848 * In peripheral mode the RX72N receives the clock signal from an external SPI
01849 * controller (Raspberry Pi 5). Performs full hardware initialization including
01850 * module stop release, pin function selection (COPI/CIPO/CLK/CS via MPC),
01851 * SPI mode register configuration, and frame size setup.
01852 *
01853 * ## Algorithm
01854 * 1. Validate channel (0-2) and config pointer
01855 * 2. Release RSPI module from module stop (MSTPCRB)
01856 * 3. Disable RSPI (SPCR.SPE = 0)
01857 * 4. Configure pin functions via MPC (COPI, CIPO, CLK, CS)
01858 * 5. Set SPI mode (CPOL/CPHA in SPCMD0)
01859 * 6. Set frame length (8-bit or 16-bit in SPCMD0)
01860 * 7. Configure as peripheral (SPCR.MSTR = 0)
01861 * 8. Enable RSPI (SPCR.SPE = 1)
01862 *
01863 * @param[in] channel RSPI channel number (0-2)
01864 * @param[in] config Pointer to peripheral mode configuration
01865 * - Must not be nullptr
01866 * - config->spi_mode must be valid (0-3)
01867 *
01868 * @return rx_err_t Error code indicating success or failure
01869 * @retval k_rx_ok Channel successfully initialized in peripheral mode
01870 * @retval k_rx_err_invalid_arg Channel > 2 or invalid SPI mode

02158 * @brief Set chip select line state for an RSPI controller-mode channel
02159 *
02160 * @details
02161 * Controls the GPIO chip select pin associated with the specified RSPI
02162 * channel operating in controller mode. The CS signal is active-low: when
02163 * active is true, the GPIO pin is driven low (CS asserted, peripheral
02164 * selected); when active is false, the pin is driven high (CS deasserted,
02165 * peripheral released). The port and pin are read from the internal
02166 * s_rspi_cs_config[] array populated during rspi_init_controller().
02167 *
02168 * This function provides direct CS control for protocols that require
02169 * multi-transfer CS framing. For single 16-bit transfers with automatic
02170 * CS handling, use rspi_controller_transfer_16bit() instead.
02171 *
02172 * @param[in] channel RSPI channel number (valid: k_rspi_channel_0,
02173 * k_rspi_channel_1, k_rspi_channel_2; range 0-2)
02174 * @param[in] active true to assert CS (drive GPIO low),
02175 * false to deassert CS (drive GPIO high)
02176 *
02177 * @return rx_err_t Error code indicating success or failure
02178 * @retval k_rx_ok CS line successfully driven to requested state
02179 * @retval k_rx_err_invalid_state channel >= 3 or channel not initialized
02180 * in controller mode via rspi_init_controller()
02181 * @retval k_rx_err_invalid_arg GPIO port base address lookup failed for
02182 * the stored CS port configuration
02183 *
02184 * @pre channel must be initialized via rspi_init_controller()
02185 * @pre s_rspi_cs_config[channel] must contain valid port/pin from init
02186 * @post GPIO P0DR bit for the CS pin reflects the requested state
02187 * @post No other GPIO pins on the same port are modified (read-modify-write)
02188 *
02189 * @note Not thread-safe. Caller must provide external synchronization when

```

```

02190 * accessing the same channel or GPIO port from multiple threads.
02191 *
02192 * @see rspi_init_controller() Configures CS pin during initialization
02193 * @see rspi_controller_transfer_16bit() Automatic CS handling for transfers
02194 * @see rspi_controller_deinit() Deasserts CS during cleanup
02195 *

## Functions

- static volatile [rx\\_s12ad\\_regs\\_t](#) \* [s12ad0](#) (void)  
Get pointer to S12AD0 (Unit 0) registers.
- static volatile [rx\\_s12ad\\_regs\\_t](#) \* [s12ad1](#) (void)  
Get pointer to S12AD1 (Unit 1) registers.

### 8.3.1 Detailed Description

#### RX72N S12AD 12-bit A/D Converter Register Definitions.

This header provides comprehensive register definitions for the RX72N's 12-bit Successive Approximation A/D Converter (S12ADFa). The S12AD is essential for motor current sensing in the STAR project's DRV8263H H-bridge motor control system.

#### System Architecture Context:

#### S12AD Unit Specifications:

| Unit   | Base Address | Channels    | Features                        |
|--------|--------------|-------------|---------------------------------|
| S12AD0 | 0x00089000   | AN000-AN007 | 8ch, high-speed, motor sensing  |
| S12AD1 | 0x00089100   | AN100-AN120 | 21ch, temp sensor, internal ref |

#### Conversion Timing (@ 60 MHz PCLKB):

| Mode        | Conversion Time | Throughput Rate |
|-------------|-----------------|-----------------|
| Single scan | ~1.0 us/ch      | ~1 MSPS         |
| Group scan  | ~0.9 us/ch      | ~1.1 MSPS       |
| Continuous  | ~0.85 us/ch     | ~1.2 MSPS       |

#### Motor Current Sensing Pin Mapping (144-pin LFQFP):

| Motor | DRV8263H Pin | ADC Channel | RX72N Pin |
|-------|--------------|-------------|-----------|
| M0    | IPROPI       | AN007       | P47       |

| Motor | DRV8263H Pin | ADC Channel | RX72N Pin |
|-------|--------------|-------------|-----------|
| M1    | IPROPI       | AN006       | P46       |
| M2    | IPROPI       | AN005       | P45       |
| M3    | IPROPI       | AN004       | P44       |

#### Hardware Requirements:

- CPU: Renesas RX72N @ 240 MHz (ICLK)
- Peripheral clock: PCLKB = 60 MHz (ADC clock source)
- ADC reference: AVCC0 = 3.3V, AVSS0 = GND
- Sample hold: Internal S&H capacitor charged during sampling phase

#### Memory Usage:

- Register structure size: 48 bytes (0x30)
- No dynamic allocation required
- Direct memory-mapped register access

#### See also

lib/rx\_hal/src/adc.c ADC implementation

RX72N Group User's Manual: Hardware, Chapter 56 (12-Bit A/D Converter)

#### NASA Power of 10 Compliance:

- Rule 1: [OK] No goto, setjmp, or recursion in inline functions
- Rule 3: [OK] Zero dynamic allocation - all registers statically mapped
- Rule 8: [OK] All constants as C23 typed enums (base addresses, offsets)
- Rule 10: [OK] Compile with -Wall -Wextra -Werror, zero warnings

#### SOLID Principles:

- S: Single responsibility - only ADC register definitions
- O: Open for extension via accessor functions, closed for modification
- I: Interface segregation - minimal required registers exposed
- D: Dependency inversion - hardware accessed via typed pointers

## Verification Status:

[PASS] VERIFIED (2026-04-20) - All base addresses and register offsets verified against RX72N Manual R01UH0824EJ0111 Table 5.1. Critical bug fixed: spurious reserved5[2] field removed; ADDR0-7 corrected from 0x22-0x30 to 0x20-0x2E.

00115 * @defgroup rx_adc_regs RX72N S12AD Register Definitions
00116 * @brief 12-bit A/D Converter hardware register interface
00117 *
00118 * @details
00119 * Provides memory-mapped register access to the RX72N S12AD peripheral
00120 * for motor current sensing applications. All register addresses and
00121 * offsets are compile-time verified via static assertions.
00122 *
00123 * @par Quick Start Example:
00124 * @code{.c}
00125 * // Read motor 0 current from AN007 (P47)
00126 * volatile rx_s12ad_regs_t* adc = s12ad0();
00127 *
00128 * // Enable channel 7 for single scan
00129 * adc->adansa0 = (1U « 7); // AN007 only
00130 *
00131 * // Configure: single scan, software trigger
00132 * adc->adcsr = 0x0000;
00133 *
00134 * // Start conversion
00135 * adc->adcsr |= 0x8000; // ADST bit
00136 *
00137 * // Wait for completion
00138 * while (adc->adcsr & 0x8000) {}
00139 *
00140 * // Read 12-bit result (right-aligned)
00141 * uint16_t raw_value = adc->addr7;
00142 *
00143 * // Convert to voltage (3.3V reference)
00144 * static const float s_vref_volts = 3.3F;
00145 * static const float s_adc_full_scale_12bit = 4095.0F;
00146 * float voltage_v = (float)raw_value * s_vref_volts / s_adc_full_scale_12bit;
00147 * @endcode
00148 *
00149 * @{
00150 */
00151
00152 /**
=====
00153 * 12-bit A/D Converter (S12ADFa) - For Current Sensing
00154 *
=====
00155 */
00156
00157 /**
00158 * @enum rx_s12ad_addresses_t
00159 * @brief S12ADFa peripheral base addresses
00160 *
00161 * @details
00162 * Hardware base addresses for the two S12AD units on RX72N. Each unit
00163 * occupies 256 bytes (0x100) of address space in the peripheral area.
00164 *
00165 * Per RX72N Manual Ch56 and Ch04 Memory Map:
00166 * - S12AD0: 0x00089000 (Unit 0, 8 high-speed channels)
00167 * - S12AD1: 0x00089100 (Unit 1, 21 channels + temperature sensor)

```

```

00168 *
00169 * @par Address Space Layout:
00170 *
00171 * | Address Range | Description |
00172 * |-----|-----|
00173 * | 0x00089000 - 0x000890FF | S12AD0 registers (Unit 0) |
00174 * | 0x00089100 - 0x000891FF | S12AD1 registers (Unit 1) |
00175 *
00176 * @par Unit Selection Guidelines:
00177 * - Use S12AD0 for motor current sensing (lower latency, 8 channels)
00178 * - Use S12AD1 for temperature monitoring (has internal sensor)
00179 *
00180 * @invariant Base addresses are 256-byte aligned (bits [7:0] = 0)
00181 * @invariant Unit spacing is exactly 0x100 bytes

CAC interrupt vector bits inside GROUPBL0 (RX72N HW Manual pp.509-519).

## Functions

- static volatile `rx_cac_regs_t * cac` (void)  
Get pointer to CAC registers.

### 8.5.1 Detailed Description

#### RX72N CAC (Clock Frequency Accuracy Measurement Circuit) Register Definitions.

Register definitions for the Clock Frequency Accuracy Measurement Circuit (CAC) module on the RX72N microcontroller. CAC measures the frequency of a target clock source against a reference clock source and raises an interrupt (FERRF / MENDF / OVFF) when the ratio drifts outside configured bounds.

#### Feature Summary

- 16-bit up-counter clocked by the measurement target clock
- Counter is sampled on the edge of the reference clock
- Upper-limit (CAULVR) / lower-limit (CALLVR) comparators
- FERRF flag + interrupt on frequency-error
- MENDF flag + interrupt on measurement-end
- OVFF flag + interrupt on counter overflow
- Optional digital filter on the external reference clock input (CACREF)

#### Use Case in STAR

MOSC (24 MHz crystal) is measured against HOCO (16 MHz internal RC). A drifted crystal (aging, mechanical damage, PCB leakage) is detected before it corrupts motor control timing; the FERRF ISR drives the motor e-stop path.

#### Hardware Requirements

| Parameter       | Value              | Notes                             |
|-----------------|--------------------|-----------------------------------|
| Base Address    | 0x0008B000         | 11-byte register block            |
| Module Stop Bit | MSTPCRC.MSTPC19    | 1 = stopped, 0 = active           |
| Group Interrupt | GROUPBL0 (vec 110) | Bits: FERRF=26, MENDF=27, OVFF=28 |
| Reset           | PORF               | All registers cleared on reset    |

#### Manual Reference

RX72N Group User's Manual: Hardware (R01UH0824EJ0111)

- Chapter 10: Clock Frequency Accuracy Measurement Circuit (CAC)
- Section 10.2: Register Descriptions, pp.392-397
- Address summary: p.236

## NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion
- Rule 2: [OK] N/A (no loops in register definitions)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] All accessor functions are single-statement
- Rule 5: [OK] N/A (hardware layer)
- Rule 6: [OK] Minimal scope
- Rule 7: [OK] N/A (no return values to check)
- Rule 8: [OK] All constants use C23 typed enums
- Rule 9: [OK] No function pointers
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

## 8.5.2 Data Structure Documentation

### 8.5.2.1 struct rx\_cac\_regs\_t

CAC Register Map Structure.

Clock Frequency Accuracy Measurement Circuit registers, laid out to match the hardware memory map described in the RX72N HW Manual Ch10.2 (pp.392-397). Packed to guarantee byte offsets; all fields volatile because hardware can update them (CASTR, CACNTBR) outside of program control.

Memory Layout Table

| Offset | Size | Field     | Type          | Description                            |
|--------|------|-----------|---------------|----------------------------------------|

### 8.5.3 Enumeration Type Documentation

#### 8.5.3.1 cac\_cacr0\_bits\_t

enum [cac\\_cacr0\\_bits\\_t](#) : uint8\_t

CAC Control Register 0 (CACR0) bit values.

CACR0 has a single active bit - CFME (Clock Frequency Measurement Enable). All other bits are reserved and must be written 0.

Register Layout (8-bit)

| Bits     | Field    | R/W | Description                           |
|----------|----------|-----|---------------------------------------|
| 0        | CFME     | R/W | 0 = measurement disabled, 1 = enabled |
| 7:↔<br>1 | Reserved | R   | Read as 0, write 0                    |

### 8.5.3.2 cac`cacr1`bits`t

enum [cac\\_cacr1\\_bits\\_t](#) : uint8\_t

CAC Control Register 1 (CACR1) bit values.

Selects the measurement target clock (FMCS), its division (TCSS), the sampling edge of CACREF (EDGES), and the CAC-interrupt enable (CAIE).

Register Layout (8-bit) - RX72N HW Manual p.393

| Bits     | Field | R/W | Description                                       |
|----------|-------|-----|---------------------------------------------------|
| 0        | CAIE  | R/W | 0 = IRQ disabled, 1 = enabled                     |
| 3:↔<br>1 | FMCS  | R/W | Measurement target clock source select            |
| 5:↔<br>4 | TCSS  | R/W | Target-clock division (div 1/4/8/32)              |
| 7:↔<br>6 | EDGES | R/W | CACREF edge: rising / falling / both / (reserved) |

FMCS[2:0

target-clock options (RX72N HW Manual p.393)]

| FMCS | Clock source       |
|------|--------------------|
| 000  | Main clock         |
| 001  | Sub-clock          |
| 010  | HOCO               |
| 011  | LOCO               |
| 100  | Peripheral B       |
| 101  | IWDTCLK            |
| 110  | UCLK (USB)         |
| 111  | 25 MHz (CLKOUT25M) |

TCSS[1:0]

target-clock divider (RX72N HW Manual p.393)]

| TCSS | Divider        |
|------|----------------|
| 00   | $\frac{1}{1}$  |
| 01   | $\frac{1}{4}$  |
| 10   | $\frac{1}{8}$  |
| 11   | $\frac{1}{32}$ |

EDGES[1:0]

CACREF valid edge (RX72N HW Manual p.393)]

| EDGES | Edge         |
|-------|--------------|
| 00    | Rising edge  |
| 01    | Falling edge |
| 10    | Both edges   |
| 11    | Reserved     |

#### 8.5.3.4 cac\_cacr2\_bits\_t

```
enum cac_cacr2_bits_t : uint8_t
```

CAC Control Register 2 (CACR2) bit values.

Selects the reference clock source (RSCS), its divider (RCDS), the digital-filter tap on the external CACREF pin (DFS), and whether the reference clock is taken from the external CACREF pin or the internal source selected by RSCS (RPS).

Register Layout (8-bit) - RX72N HW Manual p.394

| Bits     | Field | R/W | Description                              |
|----------|-------|-----|------------------------------------------|
| 0        | RPS   | R/W | 0 = internal RSCS source, 1 = CACREF pin |
| 3:↔<br>1 | RSCS  | R/W | Internal reference source select         |
| 5:↔<br>4 | RCDS  | R/W | Reference-clock divider                  |
| 7:↔<br>6 | DFS   | R/W | Digital-filter enable for CACREF pin     |

RSCS[2:0]

internal reference source (RX72N HW Manual p.394)]

| RSCS | Source       |
|------|--------------|
| 000  | Main clock   |
| 001  | Sub-clock    |
| 010  | HOCO         |
| 011  | LOCO         |
| 100  | Peripheral B |
| 101  | IWDTCLK      |

## RCDS[1:0]

reference-clock divider (RX72N HW Manual p.394)]

| RCDS | Divider |
|------|---------|
| 00   | /32     |
| 01   | /128    |
| 10   | /1024   |
| 11   | /8192   |

## DFS[1:0]

digital-filter sampling (RX72N HW Manual p.394)]

| DFS | Filter                      |
|-----|-----------------------------|
| 00  | Filter disabled             |
| 01  | Sample at target-clock rate |
| 10  | Sample at target-clock / 4  |
| 11  | Sample at target-clock / 16 |

## 8.5.3.6 cac\_caicr\_bits\_t

```
enum cac_caicr_bits_t : uint8_t
```

CAC Interrupt Control Register (CAICR) bit values.

Enables the individual interrupt sources (FERRIE/MENDIE/OVFIE) and provides write-1-to-clear bits for the status flags in CASTR (FERRFCL/MENDFCL/OVFFCL).

Register Layout (8-bit) - RX72N HW Manual p.395

| Bit | Field   | R/W | Description                       |
|-----|---------|-----|-----------------------------------|
| 0   | FERRIE  | R/W | Frequency-error interrupt enable  |
| 1   | MENDIE  | R/W | Measurement-end interrupt enable  |
| 2   | OVFIE   | R/W | Counter-overflow interrupt enable |
| 3   | -       | R   | Reserved                          |
| 4   | FERRFCL | W1C | Write 1 to clear CASTR.FERRF      |
| 5   | MENDFCL | W1C | Write 1 to clear CASTR.MENDF      |
| 6   | OVFFCL  | W1C | Write 1 to clear CASTR.OVFF       |
| 7   | -       | R   | Reserved                          |

```

### 8.5.3.7 `cac_castr_bits_t`

```
enum cac_castr_bits_t : uint8_t
```

CAC Status Register (CASTR) bit values.

Read-only status flags. Hardware sets each flag on its respective event; software clears them by writing 1 to the corresponding bit in CAICR.

Register Layout (8-bit) - RX72N HW Manual p.395

| Bit      | Field | R | Description                              |
|----------|-------|---|------------------------------------------|
| 0        | FERRF | R | 1 = counter outside [CALLVR, CAULVR]     |
| 1        | MENDF | R | 1 = measurement completed                |
| 2        | OVFF  | R | 1 = counter overflowed (exceeded 0xFFFF) |
| 7:↔<br>3 | -     | R | Reserved, read as 0                      |

00529 } cac_castr_bits_t;
```

### 8.5.3.8 `cac_groupbl0_bits_t`

```
enum cac_groupbl0_bits_t : uint8_t
```

CAC interrupt vector bits inside GROUPBL0 (RX72N HW Manual pp.509-519).

CAC shares GROUPBL0 (interrupt vector 110) with several other peripherals. The CAC-specific bits inside GRPBL0 / GCRBL0 / GENBL0 are:

| Bit | Source |
|-----|--------|
| 26  | FERRF  |
| 27  | MENDF  |
| 28  | OVFF   |

Since

Version 1.0.0

Enumerator

|                       |                           |
|-----------------------|---------------------------|
| k_cac_groupbl0_vector | GROUPBL0 vector number    |
| k_cac_groupbl0_ferrf  | FERRF bit inside GROUPBL0 |
| k_cac_groupbl0_mendf  | MENDF bit inside GROUPBL0 |
| k_cac_groupbl0_ovff   | OVFF bit inside GROUPBL0  |

Definition at line 570 of file [rx72n\\_cac\\_regs.h](#).

```

00570 : uint8_t {
00571 k_cac_groupbl0_vector = 110, /**< GROUPBL0 vector number */

00573 k_cac_groupbl0_mendf = 27, /**< MENDF bit inside GROUPBL0 */
00574 k_cac_groupbl0_ovff = 28, /**< OVFF bit inside GROUPBL0 */
00575 } cac_groupbl0_bits_t;

```

### 8.5.3.9 cac\_mstp\_info\_t

```
enum cac_mstp_info_t : uint8_t
```

Location of CAC module-stop bit in MSTPCRC (RX72N HW Manual pp.410-411).

The CAC module is gated by MSTPCRC.MSTPC19 (bit 19 of the MSTPCRC register at SYSTEM base + 0x18). Writing 1 stops the module, 0 enables it. Access requires prior PRCR unlock (PRC1).

Warning

This is informational only - the driver uses the mstpcrc field of [rx\\_system\\_regs\\_t](#) directly rather than a dedicated accessor.

## 8.5.4 Function Documentation

### 8.5.4.1 `cac()`

```
volatile rx_cac_regs_t * cac (
 void) [inline], [static]
```

Get pointer to CAC registers.

Returns a volatile pointer to the CAC register structure at `k_cac_base_addr` (0x0008B000).

Returns

Volatile pointer to CAC register structure

Return values

|          |                                                 |
|----------|-------------------------------------------------|
| Non-NULL | Always returns valid pointer (hardware address) |
|----------|-------------------------------------------------|

Note

Thread Safety: Safe - returns constant hardware address

This function is always inlined for zero overhead

```
00001 /**
00002 * @file rx72n_cac_regs.h
00003 * @brief RX72N CAC (Clock Frequency Accuracy Measurement Circuit) Register Definitions
00004 *
00005 * @details
00006 * Register definitions for the Clock Frequency Accuracy Measurement Circuit
00007 * (CAC) module on the RX72N microcontroller. CAC measures the frequency of a
00008 * target clock source against a reference clock source and raises an interrupt
00009 * (FERRF / MENDF / OVFF) when the ratio drifts outside configured bounds.
00010 *
00011 * @par Feature Summary
00012 * - 16-bit up-counter clocked by the measurement target clock
00013 * - Counter is sampled on the edge of the reference clock
00014 * - Upper-limit (CAULVR) / lower-limit (CALLVR) comparators
00015 * - FERRF flag + interrupt on frequency-error
00016 * - MENDF flag + interrupt on measurement-end
00017 * - OVFF flag + interrupt on counter overflow
00018 * - Optional digital filter on the external reference clock input (CACREF)
00019 *
00020 * @par Use Case in STAR
00021 * MOSC (24 MHz crystal) is measured against HOCO (16 MHz internal RC). A
00022 * drifted crystal (aging, mechanical damage, PCB leakage) is detected before
00023 * it corrupts motor control timing; the FERRF ISR drives the motor e-stop
```

```

00024 * path.

System clock frequencies for RX72N @ 240 MHz operation.

## 8.7.1 Detailed Description

### RX72N Clock Frequency Definitions and Configuration.

Defines all system clock frequencies for the RX72N microcontroller configured with external 24 MHz crystal and PLL x10 for maximum 240 MHz CPU operation. These constants are used throughout the firmware for timing calculations, baud rate generation, PWM frequency configuration, and peripheral initialization.

#### 8.7.1.1 Clock Generation Architecture (STAR Project)

The RX72N has a sophisticated clock generation system with multiple clock domains optimized for different purposes:

### 8.7.1.2 Clock Domain Assignments

| Clock | Frequency | Peripherals            | Purpose                        |
|-------|-----------|------------------------|--------------------------------|
| ICLK  | 240 MHz   | CPU core, DMA          | Maximum instruction throughput |
| PCLKA | 120 MHz   | CMT, TMR, MTU, GPT     | High-resolution timers for PWM |
| PCLKB | 60 MHz    | SCI (UART), RSPI, RIIC | Communication interfaces       |
| PCLKC | 60 MHz    | (Reserved)             | User peripherals               |
| PCLKD | 60 MHz    | (Reserved)             | User peripherals               |
| FCLK  | 60 MHz    | Flash controller       | Flash access (max 60 MHz)      |
| BCLK  | 120 MHz   | External bus           | External memory interface      |

### 8.7.1.3 Clock Configuration (SYSTEM Registers)

Clock frequencies are set during boot by `rx_clock_power_init()`:

1. Main Clock Enable: MOSCWTCR, MOSCCR, MOFCR registers
2. PLL Configuration: PLLCR (x10 multiplier, STC=0x13), PLLCR2 (enable)
3. Clock Dividers: SCKCR register sets ICK, PCKA, PCKB, PCKC, PCKD, FCK, BCK dividers
4. Clock Source Selection: SCKCR3 selects PLL as system clock

Register Configuration (from rx\_clock\_power\_init.c):

```
SYSTEM.SCKCR.LONG = 0x20011222; // ICK=0(/1)->240MHz, BCK=1(/2)->120MHz, PCKA=1(/2)->120MHz,
 PCKB/C/D=2(/4)->60MHz, FCK=2(/4)->60MHz
SYSTEM.PLLCR.WORD = 0x1300; // STC=19 -> x10.0 (manual p345); 24 MHz x 10 = 240 MHz
```

#### 8.7.1.4 Performance Implications

| Operation        | Clock           | Impact of Frequency                             |
|------------------|-----------------|-------------------------------------------------|
| CPU instructions | ICLK (240 MHz)  | ~4.2 ns per cycle, critical for control loops   |
| Flash access     | FCLK (60 MHz)   | ~17 ns per access, affects code execution speed |
| PWM resolution   | PCLKA (120 MHz) | 8.3 ns resolution, 20 kHz PWM = 6000 steps      |
| UART baud rate   | PCLKB (60 MHz)  | Max 3.75 Mbaud (60M/16), typical 115200 baud    |
| Timer tick       | PCLKD (60 MHz)  | ThreadX 10ms tick = 600,000 cycles per tick     |

#### 8.7.1.5 Hardware Requirements

| Requirement         | Value              | Notes                             |
|---------------------|--------------------|-----------------------------------|
| External Crystal    | 24 MHz             | +/-50 ppm accuracy required       |
| PLL Input Range     | 8-24 MHz           | 24 MHz nominal for STAR project   |
| PLL Output Range    | 200-520 MHz        | 240 MHz output (/1 for CPU)       |
| CPU Max Frequency   | 240 MHz            | Absolute max per datasheet        |
| Flash Max Frequency | 60 MHz             | Must not exceed! (hardware limit) |
| Operating Voltage   | 3.3V +/-10%        | Required for 240 MHz operation    |
| Temperature Range   | -40degC to +85degC | Industrial grade                  |

#### 8.7.1.6 Timing Calculation Examples

PWM Frequency:

$\text{PWM\_freq} = \text{PCLKA} / (\text{prescaler} \times \text{period})$   
 20 kHz = 120 MHz / (1 x 6000)

UART Baud Rate:

$\text{Baud\_rate} = \text{PCLKB} / (32 \times (N + 1))$   
 115200 = 60 MHz / (32 x (16 + 1)) -> N=16 (BRR register value)

Timer Period:

$\text{Period\_ms} = (\text{counter\_max} \times \text{prescaler}) / \text{PCLKD\_MHz}$   
 1 ms = (60000 x 1) / 60 MHz

Module Dependencies:

- NO dependencies (pure constant definitions)
- Used by: ALL timing-related modules (CMT, PWM, UART, SPI, ADC, etc.)

NASA Power of 10 Compliance:

- Rule 1: [OK] No code (only data definitions)
- Rule 2: [OK] No loops
- Rule 3: [OK] No dynamic allocation (compile-time constants)
- Rule 4: [OK] No functions
- Rule 5: [OK] N/A (no functions)
- Rule 6: [OK] File scope only (header file)
- Rule 7: [OK] No functions
- Rule 8: [OK] C23 typed enums for all constants
- Rule 9: [OK] No pointers
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

SOLID Principles:

- Single Responsibility: Only defines clock frequencies, no logic
- Open/Closed: Extensible (add new clocks) without modification
- Liskov Substitution: N/A (no inheritance)
- Interface Segregation: Minimal interface (single enum)
- Dependency Inversion: N/A (no dependencies)

Usage Example - Baud Rate Calculation:

```
#include "rx72n_clock.h"

// Calculate UART BRR register value for desired baud rate
uint8_t uart_calculate_brr(uint32_t baud_rate) {
 // Formula: BRR = (PCLKB / (32 x baud)) - 1
 uint32_t brr = (k_pclkb_hz / (32 * baud_rate)) - 1;
 return (uint8_t)brr;
}

// Example: 115200 baud
uint8_t brr = uart_calculate_brr(115200); // Returns 16
```

Usage Example - PWM Configuration:

```
// Configure PWM for 20 kHz at 50% duty cycle
void pwm_configure_20khz(void) {
 typedef enum : uint32_t {
 k_pwm_freq_hz = 20000, // Desired PWM frequency
 k_prescaler = 1, // Timer prescaler
 } pwm_config_t;

 // Calculate timer period: Period = PCLKA / (prescaler x freq)
 uint32_t period = k_pclka_hz / (k_prescaler * k_pwm_freq_hz);
 // period = 120,000,000 / (1 x 20,000) = 6000 counts

 uint32_t duty_50pct = period / 2; // 3000 counts = 50%

 gpt_set_period(GPT_CHANNEL_0, period);
 gpt_set_duty(GPT_CHANNEL_0, duty_50pct);
}
```

## Usage Example - Delay Timing:

```
// Calculate cycles for precise delay
void delay_us(uint32_t us) {
 // Cycles per microsecond at ICLK frequency
 typedef enum : uint32_t {
 k_cycles_per_us = k_ickl_hz / 1000000, // 240 cycles/us
 } delay_config_t;

 uint32_t cycles = us * k_cycles_per_us;

 // Busy-wait loop (NOP instructions)
 for (uint32_t i = 0; i < cycles / 4; i++) {
 __asm volatile("nop\nnop\nnop\nnop");
 }
}
```

## Usage Example - Timer Configuration:

```
// Configure CMT for 1ms tick (1 kHz interrupt)
void cmt_configure_1ms(void) {
 typedef enum : uint32_t {
 k_desired_freq_hz = 1000, // 1 kHz = 1ms period
 k_cmt_prescaler = 8, // CMT prescaler (PCLKD/8)
 } cmt_config_t;

 // Calculate compare match value
 // CMCOR = (PCLKD / prescaler / freq) - 1
 uint32_t cmcor = (k_pclkd_hz / k_cmt_prescaler / k_desired_freq_hz) - 1;
 // cmcor = (60,000,000 / 8 / 1000) - 1 = 7499

 CMT0.CMCOR = (uint16_t)cmcor;
}
```

## 8.7.2 Enumeration Type Documentation

### 8.7.2.1 rx\_clock\_frequencies\_t

```
enum rx_clock_frequencies_t : uint32_t
```

System clock frequencies for RX72N @ 240 MHz operation.

Defines all clock domain frequencies for the STAR project's RX72N configuration. These values are determined by the PLL and clock divider settings in rx\_clock\_power\_init() and are guaranteed to be accurate for timing calculations.

Clock Source: 24 MHz external crystal -> PLL (x10) -> 240 MHz -> divided per domain

Frequency Derivation:

- PLL output: 24 MHz x 10 = 240 MHz
- ICLK: 240 MHz / 1 = 240 MHz (CPU)
- PCLKA: 240 MHz / 2 = 120 MHz (high-speed peripherals)
- PCLKB/C/D: 240 MHz / 4 = 60 MHz (standard peripherals)
- FCLK: 240 MHz / 4 = 60 MHz (flash - max allowed)
- BCLK: 240 MHz / 2 = 120 MHz (external bus - not used in STAR)

### 8.7.2.2 Clock Domain Usage Table

| Clock | Freq    | Used By            | STAR Project Usage                          |
|-------|---------|--------------------|---------------------------------------------|
| ICLK  | 240 MHz | CPU core           | PID control loop, communication protocol    |
| PCLKA | 120 MHz | MTU, GPT, CMT, TMR | Encoder capture (MTU), PWM generation (GPT) |
| PCLKB | 60 MHz  | SCI, RSPI, RIIC    | UART debug, SPI to RPi5, I2C sensors        |
| PCLKC | 60 MHz  | (Reserved)         | Not used in STAR project                    |
| PCLKD | 60 MHz  | CMT                | ThreadX system tick (10ms)                  |
| FCLK  | 60 MHz  | Flash              | Code execution, const data access           |
| BCLK  | 120 MHz | External bus       | Not used (no external memory)               |

Field Constraints:

| Constant   | Min   | Max     | Notes                                     |
|------------|-------|---------|-------------------------------------------|
| k_ick_hz   | 1 MHz | 240 MHz | 240 MHz is absolute max per datasheet     |
| k_pclka_hz | 1 MHz | 240 MHz | Limited by ICLK (cannot exceed CPU clock) |
| k_pclkb_hz | 1 MHz | 60 MHz  | Communication peripherals rated to 60 MHz |
| k_fclk_hz  | 1 MHz | 60 MHz  | MUST NOT EXCEED 60 MHz (flash limit)      |

Usage Example - Calculate Timer Period:

```
// Calculate CMT compare value for 100 Hz interrupt (10ms period)
typedef enum : uint32_t {
 k_desired_freq_hz = 100, // 100 Hz = 10ms period
 k_cmt_prescaler = 8, // PCLKD/8
} timer_config_t;

uint32_t cmcor = (k_pclkd_hz / k_cmt_prescaler / k_desired_freq_hz) - 1;
// cmcor = (60,000,000 / 8 / 100) - 1 = 74,999
```

```

00286 : uint32_t {
00287 /**
00288 * @brief CPU core clock frequency (ICLK) - 240 MHz
00289 *
00290 * @details
00291 * The instruction clock (ICLK) drives the RX72N CPU core, DMA controller,
00292 * and internal buses. This is the primary determinant of computational
00293 * throughput and interrupt latency.
00294 */

```

```

00295 * **Value**: 240,000,000 Hz (240 MHz)
00296 * **Source**: PLL output (240 MHz) divided by 1
00297 * **Cycle time**: 4.17 nanoseconds per cycle
00298 * **Register**: SYSTEM.SCKCR.ICK (divider = b'0000' = /1 from PLL)
00299 *
00300 * **Performance Metrics** @ 240 MHz:
00301 * - Single-cycle instructions: 4.17 ns (e.g., MOV, ADD)
00302 * - Flash access: ~20 ns (5 cycles with wait states)
00303 * - Branch misprediction penalty: ~8 ns (2 cycles)
00304 * - Interrupt latency: ~200 ns (minimum, no context save)
00305 *
00306 * **Use Cases in STAR Project**:
00307 * - PID control loop execution (~2 us per motor update @ -O2)
00308 * - Protocol parsing (nanopb decode ~50 us for 256-byte frame)
00309 * - Floating-point math (division ~20 cycles = 83 ns)
00310 * - Critical timing operations (encoder pulse measurement)
00311 *
00312 * **Rationale**: Maximum frequency selected for:
00313 * - Minimize control loop latency (100 Hz loop = 10ms budget)
00314 * - Fast protocol processing (SPI @ 10 Mbps = 25.6 us per 32-byte frame)
00315 * - Headroom for future features (current usage ~30% of CPU)
00316 *
00317 * @par Impact of Changing:
00318 * - **Increase**: Not possible (240 MHz is absolute max)
00319 * - **Decrease**: Proportional reduction in throughput, may cause control loop overruns
00320 *
00321 * @warning Flash wait states increase CPU power consumption. Use '-O2' optimization
00322 * to minimize instruction count and reduce power.
00323 *
00324 * @see k_fclk_hz Flash clock must stay <=60 MHz regardless of ICLK
00325 */
00326 k_ickl_hz = 240000000UL,
00327
00328 /**
00329 * @brief Peripheral Clock A (PCLKA) - 120 MHz
00330 *
00331 * @details
00332 * High-speed peripheral clock for time-critical functions: timers for PWM
00333 * generation (GPT), encoder capture (MTU), and high-resolution timing (CMT).
00334 *
00335 * **Value**: 120,000,000 Hz (120 MHz)
00336 * **Source**: 24 MHz main oscillator -> PLL x10 = 240 MHz -> PCKA divider /2
00337 * **Cycle time**: ~8.33 nanoseconds per cycle
00338 * **Register**: SYSTEM.SCKCR = 0x20011222 (PCKA[15:12] = 1 = divide-by-2 from 240 MHz PLL)
00339 *
00340 * **Connected Peripherals**:
00341 * - **MTU (Multi-Function Timer)**: Encoder quadrature capture (4 motors)
00342 * - **GPT (General PWM Timer)**: Motor PWM generation (4 H-bridges)
00343 * - **CMT (Compare Match Timer)**: System tick, delay timers
00344 * - **TMR (8/16-bit Timer)**: Miscellaneous timing functions
00345 *
00346 * **Performance Analysis**:
00347 *
00348 * **PWM Resolution @ 20 kHz**:
00349 * ```
00350 * Period = PCLKA / PWM_freq = 120,000,000 / 20,000 = 6000 counts
00351 * Resolution = 100% / 6000 = 0.0167% per count
00352 * Voltage resolution (12V supply) = 12V x 0.0167% = 2 mV per step
00353 * ```
00354 *
00355 * **Encoder Capture Precision**:
00356 * ```
00357 * Max velocity = 2.5 m/s (STAR robot spec)
00358 * Wheel diameter = 0.1 m -> circumference = 0.314 m
00359 * Max RPM = (2.5 m/s / 0.314 m) x 60 = 477 RPM
00360 * Encoder PPR = 341 x 4 (quadrature) = 1364 edges/rev
00361 * Max edge rate = 477 RPM x 1364 edges / 60 = 10,836 edges/sec
00362 * Min edge period = 1 / 10,836 = 92.3 us
00363 * Timer counts per edge @ 120 MHz = 92.3 us x 120 MHz = 11,076 counts
00364 * Velocity resolution = 1 count / 11,076 = 0.009% per timer count [OK]
00365 * ```
00366 *
00367 * **Rationale**: 120 MHz chosen for:
00368 * - PWM resolution: 6000 steps @ 20 kHz (excellent granularity)
00369 * - Encoder precision: 0.009% velocity measurement resolution
00370 * - Timer headroom: Max edge rate only uses 10% of timer bandwidth
00371 *
00372 * @par Impact of Changing:
00373 * - **Increase to 240 MHz**: Double PWM resolution (12000 steps), but wastes power
00374 * - **Decrease to 60 MHz**: Half PWM resolution (3000 steps), still acceptable
00375 *
00376 * @warning GPT, MTU, CMT baud rate calculations assume 120 MHz. Changing PCLKA
00377 * requires recalculating all timer prescalers and compare values.
00378 */

```

00382 * @brief Peripheral Clock B (PCLKB) - 60 MHz
00383 *
00384 * @details
00385 * Standard-speed peripheral clock for communication interfaces: UART serial
00386 * console, SPI to Raspberry Pi 5, and I2C sensor bus.
00387 *
00388 * **Value**: 60,000,000 Hz (60 MHz)
00389 * **Source**: ICLK (240 MHz) divided by 4
00390 * **Cycle time**: 16.67 nanoseconds per cycle
00391 * **Register**: SYSTEM.SCKCR.PCKB (divider = b'0010' = /4 from ICLK)
00392 *
00393 * **Connected Peripherals**:
00394 * - **SCI (Serial Communication Interface)**: UART for USB CDC debug console
00395 * - **RSPi (Renesas SPI)**: SPI controller for RPi5 communication
00396 * - **RIIC (Renesas I2C)**: I2C controller for sensor bus (IMU, lidar interface)
00397 *
00398 * **Baud Rate Capabilities**:
00399 *
00400 * **UART (SCI) @ 115200 baud**:
00401 * ```
00402 * BRR = (PCLKB / (32 x baud_rate)) - 1
00403 * BRR = (60,000,000 / (32 x 115200)) - 1 = 16.276... ~ 16
00404 * Actual baud = 60,000,000 / (32 x 17) = 110,294 baud
00405 * Error = (110,294 - 115200) / 115200 = -4.3% (within +/-5% tolerance) [OK]
00406 * ```
00407 *
00408 * **SPI (RSPi) @ 10 Mbps** (STAR project: communication with RPi5):
00409 * ```
00410 * SPI_bitrate = PCLKB / (2 x (SPBR + 1))
00411 * 10 Mbps = 60,000,000 / (2 x (SPBR + 1))
00412 * SPBR = (60,000,000 / (2 x 10,000,000)) - 1 = 2
00413 * Actual rate = 60,000,000 / (2 x 3) = 10 Mbps exact [OK]
00414 * ```
00415 *
00416 * **I2C (RIIC) @ 400 kHz** (Fast-mode I2C for IMU):
00417 * ```
00418 * I2C_freq = PCLKB / (CKS x (BRL + BRH + 4))
00419 * 400 kHz typical with CKS=0 (prescaler /1), BRL=BRH=73
00420 * Actual = 60,000,000 / (1 x (73 + 73 + 4)) = 400 kHz exact [OK]
00421 * ```
00422 *
00423 * **Rationale**: 60 MHz chosen for:
00424 * - UART: Standard baud rates (9600, 19200, 115200) achievable with <5% error
00425 * - SPI: 10 Mbps target rate (STAR requirement) achievable exactly
00426 * - I2C: 100 kHz (standard) and 400 kHz (fast-mode) both supported
00427 * - Power: Lower clock = lower power for communication peripherals
00428 *
00429 * @par Impact of Changing:
00430 * - **Increase to 120 MHz**: Would allow 20 Mbps SPI, but RPi5 limited to 10 Mbps
00431 * - **Decrease to 30 MHz**: Would limit SPI to 5 Mbps, still acceptable
00432 *
00433 * @warning All UART/SPI/I2C drivers assume 60 MHz PCLKB. Changing requires
00434 * recalculating all BRR/SPBR register values.
00435 */

00440 *
00441 * @details
00442 * General-purpose peripheral clock, currently unused in STAR project.
00443 * Available for future expansion or custom peripherals.
00444 *
00445 * **Value**: 60,000,000 Hz (60 MHz)
00446 * **Source**: ICLK (240 MHz) divided by 4
00447 * **Register**: SYSTEM.SCKCR.PCKC (divider = b'0010' = /4 from ICLK)
00448 *
00449 * **Rationale**: Configured to 60 MHz (matching PCLKB/D) for:
00450 * - Consistency: All general-purpose clocks run at same frequency
00451 * - Power: Lower clock reduces power consumption of unused peripherals
00452 * - Future-proofing: Standard communication peripheral clock if needed
00453 *
00454 * @warning Not currently used. Changing has no effect on STAR functionality.
00455 */
00456 k_pclkc_hz = 60000000UL,
00457
00458 /**
00459 * @brief Peripheral Clock D (PCLKD) - 60 MHz
00460 *
00461 * @details
00462 * General-purpose peripheral clock, used in STAR project for CMT system tick
00463 * timer that drives ThreadX RTOS scheduling.
00464 *
00465 * **Value**: 60,000,000 Hz (60 MHz)
00466 * **Source**: ICLK (240 MHz) divided by 4
00467 * **Cycle time**: 16.67 nanoseconds per cycle
00468 * **Register**: SYSTEM.SCKCR.PCKD (divider = b'0010' = /4 from ICLK)

```

```

00469 *
00470 * **Connected Peripherals**:
00471 * - **CMT (Compare Match Timer)**: ThreadX 10ms system tick
00472 *
00473 * **ThreadX Tick Configuration**:
00474 * ```
00475 * Tick frequency = 100 Hz (10ms period)
00476 * CMT prescaler = PCLKD / 8 = 60 MHz / 8 = 7.5 MHz
00477 * Compare value = (7.5 MHz / 100 Hz) - 1 = 75,000 - 1 = 74,999
00478 * Actual period = 75,000 / 7.5 MHz = 10.000 ms exact [OK]
00479 * ```
00480 *
00481 * **Rationale**: 60 MHz chosen for:
00482 * - ThreadX tick: Integer divider achieves exact 10ms period
00483 * - Power: Lower clock reduces CMT power consumption
00484 * - Flexibility: High enough for sub-millisecond timing if needed
00485 *
00486 * @par Impact of Changing:
00487 * - **Increase to 120 MHz**: Would double timer resolution, but overkill for 10ms tick
00488 * - **Decrease to 30 MHz**: Would halve resolution, still sufficient for 10ms tick
00489 *
00490 * @warning ThreadX configuration assumes 100 Hz tick (10ms). Changing PCLKD
00491 * requires reconfiguring CMT compare value in rx_cmt.c.
00492 */
00493 k_pclkd_hz = 60000000UL,
00494
00495 /**
00496 * @brief External Bus Clock (BCLK) - 120 MHz (unused in STAR project)
00497 *
00498 * @details
00499 * Clock for external memory interface (SDRAM, SRAM, NOR flash). Not used in
00500 * STAR project as all code/data fits in internal 4MB flash + 512KB SRAM.
00501 *
00502 * **Value**: 120,000,000 Hz (120 MHz)
00503 * **Source**: ICLK (240 MHz) divided by 2
00504 * **Register**: SYSTEM.SCKCR.BCK (divider = b'0001' = /2 from ICLK)
00505 *
00506 * **Rationale**: Configured to 120 MHz despite being unused because:
00507 * - Default safe value (does not affect internal operation)
00508 * - Matches PCLKA (high-speed peripheral clock)
00509 * - Future-proofing if external memory added later
00510 *
00511 * @warning Not used in STAR (no external bus devices). Changing has no effect.
00512 */
00513 k_bclk_hz = 120000000UL,
00514
00515 /**
00516 * @brief Flash Memory Clock (FCLK) - 60 MHz (hardware limit)
00517 *
00518 * @details
00519 * Clock for internal flash controller (code fetch, const data access). This
00520 * frequency MUST NOT EXCEED 60 MHz per RX72N datasheet, regardless of CPU
00521 * clock speed.
00522 *
00523 * **Value**: 60,000,000 Hz (60 MHz)
00524 * **Source**: ICLK (240 MHz) divided by 4
00525 * **Cycle time**: 16.67 nanoseconds per cycle
00526 * **Register**: SYSTEM.SCKCR.FCK (divider = b'0010' = /4 from ICLK)
00527 *
00528 * **Flash Access Characteristics**:
00529 * - **1-wait access**: 16.67 ns + wait state ~ 20 ns per access
00530 * - **CPU cycles per access**: 20 ns / 4.17 ns = ~5 CPU cycles
00531 * - **Code throughput**: ~48 million instructions/sec (if 1 fetch per instruction)
00532 * - **Actual throughput**: Higher due to caching and instruction pipelining
00533 *
00534 * **Wait State Configuration** (FACI.FWEPROR register):
00535 * ```
00536 * ICLK = 240 MHz, FCLK = 60 MHz
00537 * Wait states = 1 (minimum for 60 MHz FCLK @ 240 MHz ICLK)
00538 * Access time = 1 FCLK cycle + 1 wait = 33.3 ns
00539 * ```
00540 *
00541 * **Performance Impact**:
00542 * - Flash access is slower than SRAM (5 cycles vs 1 cycle)
00543 * - Critical loops should use SRAM ('__attribute__((section(".data")))')
00544 * - Const data in flash adds latency vs SRAM variables
00545 *
00546 * **Rationale**: 60 MHz is MAXIMUM allowed by hardware:
00547 * - Exceeding 60 MHz causes flash corruption and data loss
00548 * - Lower frequencies (30 MHz) would reduce throughput unnecessarily
00549 * - 60 MHz balances speed and hardware safety limit
00550 *
00551 * @par Impact of Changing:
00552 * - **Increase >60 MHz**: **FORBIDDEN** - Violates datasheet, causes corruption
00553 * - **Decrease to 30 MHz**: Halves flash throughput, increases code execution time
00554 *
00555 * @warning **CRITICAL**: FCLK MUST NOT EXCEED 60 MHz under any circumstances.

```

```

00556 * Flash controller will malfunction if overclocked, leading to data
00557 * corruption, crashes, and potential permanent flash damage.
00558 *
00559 * @attention If increasing ICLK in future, MUST adjust FCK divider to keep
00560 * FCLK <=60 MHz. Example: ICLK=480 MHz requires FCK divider /8.
00561 */
00562 k_fclk_hz = 60000000UL,
00563
00564 } rx_clock_frequencies_t;

## 8.8 rx72n\_clock.h

[Go to the documentation of this file.](#)

```

00001 /**
00002 * @file rx72n_clock.h
00003 * @brief RX72N Clock Frequency Definitions and Configuration
00004 *
00005 * @details
00006 * Defines all system clock frequencies for the RX72N microcontroller configured
00007 * with external 24 MHz crystal and PLL x10 for maximum 240 MHz CPU operation.
00008 * These constants are used throughout the firmware for timing calculations,
00009 * baud rate generation, PWM frequency configuration, and peripheral initialization.
00010 *
00011 * ## Clock Generation Architecture (STAR Project)
00012 *
00013 * The RX72N has a sophisticated clock generation system with multiple clock
00014 * domains optimized for different purposes:
00015 *
00016 * @dot
00017 * digraph clock_tree {
00018 * rankdir=LR;
00019 * node [shape=box, style=rounded];
00020 *
00021 * EXTAL [label="External Crystal\n24 MHz", shape=ellipse, fillcolor=lightyellow, style=filled];
00022 * PLL [label="PLL\nx10", fillcolor=lightblue, style=filled];
00023 * ICLK [label="ICLK\n240 MHz\nCPU", fillcolor=lightgreen, style=filled];
00024 * PCLKA [label="PCLKA\n120 MHz\nTimers", fillcolor=lightpink, style=filled];
00025 * PCLKB [label="PCLKB\n60 MHz\nUART/SPI", fillcolor=lightpink, style=filled];
00026 * PCLKC [label="PCLKC\n60 MHz\nPWM", fillcolor=lightpink, style=filled];
00027 * PCLKD [label="PCLKD\n60 MHz\nCMT", fillcolor=lightpink, style=filled];
00028 * FCLK [label="FCLK\n60 MHz\nFlash", fillcolor=lightcyan, style=filled];
00029 * BCLK [label="BCLK\n120 MHz\nExt Bus", fillcolor=lightgray, style=filled];
00030 *
00031 * EXTAL -> PLL [label="24 MHz"];
00032 * PLL -> ICLK [label="240 MHz\n/1"];
00033 * PLL -> PCLKA [label="/2"];
00034 * PLL -> PCLKB [label="/4"];
00035 * PLL -> PCLKC [label="/4"];
00036 * PLL -> PCLKD [label="/4"];
00037 * PLL -> FCLK [label="/4"];
00038 * PLL -> BCLK [label="/2"];
00039 * }
00040 * @enddot
00041 *
00042 * ## Clock Domain Assignments
00043 *
00044 * | Clock | Frequency | Peripherals | Purpose |
00045 * |-----|-----|-----|-----|
00046 * | ICLK | 240 MHz | CPU core, DMA | Maximum instruction throughput |
00047 * | PCLKA | 120 MHz | CMT, TMR, MTU, GPT | High-resolution timers for PWM |
00048 * | PCLKB | 60 MHz | SCI (UART), RSPI, RIIC | Communication interfaces |
00049 * | PCLKC | 60 MHz | (Reserved) | User peripherals |
00050 * | PCLKD | 60 MHz | (Reserved) | User peripherals |
00051 * | FCLK | 60 MHz | Flash controller | Flash access (max 60 MHz) |
00052 * | BCLK | 120 MHz | External bus | External memory interface |
00053 *
00054 * ## Clock Configuration (SYSTEM Registers)
00055 *
00056 * Clock frequencies are set during boot by `rx_clock_power_init()`:
00057 *
00058 * 1. **Main Clock Enable**: MOSCWTCR, MOSCCR, MOFCR registers
00059 * 2. **PLL Configuration**: PLLCR (x10 multiplier, STC=0x13), PLLCR2 (enable)
00060 * 3. **Clock Dividers**: SCKCR register sets ICK, PCKA, PCKB, PCKC, PCKD, FCK, BCK dividers
00061 * 4. **Clock Source Selection**: SCKCR3 selects PLL as system clock
00062 *
00063 * **Register Configuration** (from rx_clock_power_init.c):
00064 * ```
00065 * SYSTEM.SCKCR.LONG = 0x20011222; // ICK=0/(1)->240MHz, BCK=1/(2)->120MHz, PCKA=1/(2)->120MHz,
 PCKB/C/D=2/(4)->60MHz, FCK=2/(4)->60MHz
00066 * SYSTEM.PLLCR.WORD = 0x1300; // STC=19 -> x10.0 (manual p345); 24 MHz x 10 = 240 MHz
00067 * ```

```

```

00068 *
00069 * ## Performance Implications
00070 *
00071 * | Operation | Clock | Impact of Frequency |
00072 * |-----|-----|-----|
00073 * | CPU instructions | ICLK (240 MHz) | ~4.2 ns per cycle, critical for control loops |
00074 * | Flash access | FCLK (60 MHz) | ~17 ns per access, affects code execution speed |
00075 * | PWM resolution | PCLKA (120 MHz) | 8.3 ns resolution, 20 kHz PWM = 6000 steps |
00076 * | UART baud rate | PCLKB (60 MHz) | Max 3.75 Mbaud (60M/16), typical 115200 baud |
00077 * | Timer tick | PCLKD (60 MHz) | ThreadX 10ms tick = 600,000 cycles per tick |
00078 *
00079 * ## Hardware Requirements
00080 *
00081 * | Requirement | Value | Notes |
00082 * |-----|-----|-----|
00083 * | External Crystal | 24 MHz | +/-50 ppm accuracy required |
00084 * | PLL Input Range | 8-24 MHz | 24 MHz nominal for STAR project |
00085 * | PLL Output Range | 200-520 MHz | 240 MHz output (/1 for CPU) |
00086 * | CPU Max Frequency | 240 MHz | Absolute max per datasheet |
00087 * | Flash Max Frequency | 60 MHz | Must not exceed! (hardware limit) |
00088 * | Operating Voltage | 3.3V +/-10% | Required for 240 MHz operation |
00089 * | Temperature Range | -40degC to +85degC | Industrial grade |
00090 *
00091 * ## Timing Calculation Examples
00092 *
00093 * **PWM Frequency**:
00094 * ```
00095 * PWM_freq = PCLKA / (prescaler x period)
00096 * 20 kHz = 120 MHz / (1 x 6000)
00097 * ```
00098 *
00099 * **UART Baud Rate**:
00100 * ```
00101 * Baud_rate = PCLKB / (32 x (N + 1))
00102 * 115200 = 60 MHz / (32 x (16 + 1)) -> N=16 (BRR register value)
00103 * ```
00104 *
00105 * **Timer Period**:
00106 * ```
00107 * Period_ms = (counter_max x prescaler) / PCLKD_MHz
00108 * 1 ms = (60000 x 1) / 60 MHz
00109 * ```
00110 *
00111 * @par Module Dependencies:
00112 * - **NO dependencies** (pure constant definitions)
00113 * - Used by: ALL timing-related modules (CMT, PWM, UART, SPI, ADC, etc.)
00114 *
00115 * @par NASA Power of 10 Compliance:
00116 * - **Rule 1**: [OK] No code (only data definitions)
00117 * - **Rule 2**: [OK] No loops
00118 * - **Rule 3**: [OK] No dynamic allocation (compile-time constants)
00119 * - **Rule 4**: [OK] No functions
00120 * - **Rule 5**: [OK] N/A (no functions)
00121 * - **Rule 6**: [OK] File scope only (header file)
00122 * - **Rule 7**: [OK] No functions
00123 * - **Rule 8**: [OK] C23 typed enums for all constants
00124 * - **Rule 9**: [OK] No pointers
00125 * - **Rule 10**: [OK] Compiles with -Wall -Wextra -Werror
00126 *
00127 * @par SOLID Principles:
00128 * - **Single Responsibility**: Only defines clock frequencies, no logic
00129 * - **Open/Closed**: Extensible (add new clocks) without modification
00130 * - **Liskov Substitution**: N/A (no inheritance)
00131 * - **Interface Segregation**: Minimal interface (single enum)
00132 * - **Dependency Inversion**: N/A (no dependencies)
00133 *
00134 * @par Usage Example - Baud Rate Calculation:
00135 * @code{.c}
00136 * #include "rx72n_clock.h"
00137 *
00138 * // Calculate UART BRR register value for desired baud rate
00139 * uint8_t uart_calculate_brr(uint32_t baud_rate) {
00140 * // Formula: BRR = (PCLKB / (32 x baud)) - 1
00141 * uint32_t brr = (k_pclkb_hz / (32 * baud_rate)) - 1;
00142 * return (uint8_t)brr;
00143 * }
00144 *
00145 * // Example: 115200 baud
00146 * uint8_t brr = uart_calculate_brr(115200); // Returns 16
00147 * @endcode
00148 *
00149 * @par Usage Example - PWM Configuration:
00150 * @code{.c}
00151 * // Configure PWM for 20 kHz at 50% duty cycle
00152 * void pwm_configure_20khz(void) {
00153 * typedef enum : uint32_t {
00154 * k_pwm_freq_hz = 20000, // Desired PWM frequency

```

```

00155 * k_prescaler = 1, // Timer prescaler
00156 * } pwm_config_t;
00157 *
00158 * // Calculate timer period: Period = PCLKA / (prescaler x freq)
00159 * uint32_t period = k_pclka_hz / (k_prescaler * k_pwm_freq_hz);
00160 * // period = 120,000,000 / (1 x 20,000) = 6000 counts
00161 *
00162 * uint32_t duty_50pct = period / 2; // 3000 counts = 50%
00163 *
00164 * gpt_set_period(GPT_CHANNEL_0, period);
00165 * gpt_set_duty(GPT_CHANNEL_0, duty_50pct);
00166 * }
00167 * @endcode
00168 *
00169 * @par Usage Example - Delay Timing:
00170 * @code{.c}
00171 * // Calculate cycles for precise delay
00172 * void delay_us(uint32_t us) {
00173 * // Cycles per microsecond at ICLK frequency
00174 * typedef enum : uint32_t {
00175 * k_cycles_per_us = k_ickl_hz / 1000000, // 240 cycles/us
00176 * } delay_config_t;
00177 *
00178 * uint32_t cycles = us * k_cycles_per_us;
00179 *
00180 * // Busy-wait loop (NOP instructions)
00181 * for (uint32_t i = 0; i < cycles / 4; i++) {
00182 * __asm volatile("nop\nnop\nnop\nnop");
00183 * }
00184 * }
00185 * @endcode
00186 *
00187 * @par Usage Example - Timer Configuration:
00188 * @code{.c}
00189 * // Configure CMT for 1ms tick (1 kHz interrupt)
00190 * void cmt_configure_1ms(void) {
00191 * typedef enum : uint32_t {
00192 * k_desired_freq_hz = 1000, // 1 kHz = 1ms period
00193 * k_cmt_prescaler = 8, // CMT prescaler (PCLKD/8)
00194 * } cmt_config_t;
00195 *
00196 * // Calculate compare match value
00197 * // CMCOR = (PCLKD / prescaler / freq) - 1
00198 * uint32_t cmcor = (k_pclkd_hz / k_cmt_prescaler / k_desired_freq_hz) - 1;
00199 * // cmcor = (60,000,000 / 8 / 1000) - 1 = 7499
00200 *
00201 * CMT0.CMCOR = (uint16_t)cmcor;
00202 * }
00203 * @endcode

00232 /**
00233 * @enum rx_clock_frequencies_t
00234 * @brief System clock frequencies for RX72N @ 240 MHz operation
00235 *
00236 * @details
00237 * Defines all clock domain frequencies for the STAR project's RX72N configuration.
00238 * These values are determined by the PLL and clock divider settings in
00239 * rx_clock_power_init() and are guaranteed to be accurate for timing calculations.

```

```

00240 *
00241 * **Clock Source**: 24 MHz external crystal -> PLL (x10) -> 240 MHz -> divided per domain
00242 *
00243 * **Frequency Derivation**:
00244 * - PLL output: 24 MHz x 10 = 240 MHz
00245 * - ICLK: 240 MHz / 1 = 240 MHz (CPU)
00246 * - PCLKA: 240 MHz / 2 = 120 MHz (high-speed peripherals)
00247 * - PCLKB/C/D: 240 MHz / 4 = 60 MHz (standard peripherals)
00248 * - FCLK: 240 MHz / 4 = 60 MHz (flash - max allowed)
00249 * - BCLK: 240 MHz / 2 = 120 MHz (external bus - not used in STAR)
00250 *
00251 * ## Clock Domain Usage Table
00252 *
00253 * | Clock | Freq | Used By | STAR Project Usage |
00254 * |-----|-----|-----|-----|
00255 * | ICLK | 240 MHz | CPU core | PID control loop, communication protocol |
00256 * | PCLKA | 120 MHz | MTU, GPT, CMT, TMR | Encoder capture (MTU), PWM generation (GPT) |
00257 * | PCLKB | 60 MHz | SCI, RSPI, RIIC | UART debug, SPI to RPi5, I2C sensors |
00258 * | PCLKC | 60 MHz | (Reserved) | Not used in STAR project |
00259 * | PCLKD | 60 MHz | CMT | ThreadX system tick (10ms) |
00260 * | FCLK | 60 MHz | Flash | Code execution, const data access |
00261 * | BCLK | 120 MHz | External bus | Not used (no external memory) |
00262 *
00263 * @par Field Constraints:
00264 * | Constant | Min | Max | Notes |
00265 * |-----|-----|-----|-----|
00266 * | k_ickl_hz | 1 MHz | 240 MHz | 240 MHz is absolute max per datasheet |
00267 * | k_pclka_hz | 1 MHz | 240 MHz | Limited by ICLK (cannot exceed CPU clock) |
00268 * | k_pclkb_hz | 1 MHz | 60 MHz | Communication peripherals rated to 60 MHz |
00269 * | k_fclk_hz | 1 MHz | 60 MHz | **MUST NOT EXCEED 60 MHz** (flash limit) |
00270 *
00271 * @par Usage Example - Calculate Timer Period:
00272 * @code{.c}
00273 * // Calculate CMT compare value for 100 Hz interrupt (10ms period)
00274 * typedef enum : uint32_t {
00275 * k_desired_freq_hz = 100, // 100 Hz = 10ms period
00276 * k_cmt_prescaler = 8, // PCLKD/8
00277 * } timer_config_t;
00278 *
00279 * uint32_t cmcwr = (k_pclkd_hz / k_cmt_prescaler / k_desired_freq_hz) - 1;
00280 * // cmcwr = (60,000,000 / 8 / 100) - 1 = 74,999
00281 * @endcode
00282 *
00283 * @see rx_clock_power_init() Function that configures these frequencies
00284 * @since Version 1.0.0
00285 */
00286 typedef enum : uint32_t {
00287 /**
00288 * @brief CPU core clock frequency (ICLK) - 240 MHz
00289 *
00290 * @details
00291 * The instruction clock (ICLK) drives the RX72N CPU core, DMA controller,
00292 * and internal buses. This is the primary determinant of computational
00293 * throughput and interrupt latency.
00294 *
00295 * **Value**: 240,000,000 Hz (240 MHz)
00296 * **Source**: PLL output (240 MHz) divided by 1
00297 * **Cycle time**: 4.17 nanoseconds per cycle
00298 * **Register**: SYSTEM.SCKCR.ICK (divider = b'0000' = /1 from PLL)
00299 *
00300 * **Performance Metrics** @ 240 MHz:
00301 * - Single-cycle instructions: 4.17 ns (e.g., MOV, ADD)
00302 * - Flash access: ~20 ns (5 cycles with wait states)
00303 * - Branch misprediction penalty: ~8 ns (2 cycles)
00304 * - Interrupt latency: ~200 ns (minimum, no context save)
00305 *
00306 * **Use Cases in STAR Project**:
00307 * - PID control loop execution (~2 us per motor update @ -O2)
00308 * - Protocol parsing (nanopb decode ~50 us for 256-byte frame)
00309 * - Floating-point math (division ~20 cycles = 83 ns)
00310 * - Critical timing operations (encoder pulse measurement)
00311 *
00312 * **Rationale**: Maximum frequency selected for:
00313 * - Minimize control loop latency (100 Hz loop = 10ms budget)
00314 * - Fast protocol processing (SPI @ 10 Mbps = 25.6 us per 32-byte frame)
00315 * - Headroom for future features (current usage ~30% of CPU)
00316 *
00317 * @par Impact of Changing:
00318 * - **Increase**: Not possible (240 MHz is absolute max)
00319 * - **Decrease**: Proportional reduction in throughput, may cause control loop overruns
00320 *
00321 * @warning Flash wait states increase CPU power consumption. Use -O2 optimization
00322 * to minimize instruction count and reduce power.
00323 *
00324 * @see k_fclk_hz Flash clock must stay <=60 MHz regardless of ICLK
00325 */
00326 k_ickl_hz = 240000000UL,

```

```

00327
00328 /**
00329 * @brief Peripheral Clock A (PCLKA) - 120 MHz
00330 *
00331 * @details
00332 * High-speed peripheral clock for time-critical functions: timers for PWM
00333 * generation (GPT), encoder capture (MTU), and high-resolution timing (CMT).
00334 *
00335 * **Value**: 120,000,000 Hz (120 MHz)
00336 * **Source**: 24 MHz main oscillator -> PLL x10 = 240 MHz -> PCKA divider /2
00337 * **Cycle time**: ~8.33 nanoseconds per cycle
00338 * **Register**: SYSTEM.SCKCR = 0x20011222 (PCKA[15:12] = 1 = divide-by-2 from 240 MHz PLL)
00339 *
00340 * **Connected Peripherals**:
00341 * - **MTU (Multi-Function Timer)**: Encoder quadrature capture (4 motors)
00342 * - **GPT (General PWM Timer)**: Motor PWM generation (4 H-bridges)
00343 * - **CMT (Compare Match Timer)**: System tick, delay timers
00344 * - **TMR (8/16-bit Timer)**: Miscellaneous timing functions
00345 *
00346 * **Performance Analysis**:
00347 *
00348 * **PWM Resolution @ 20 kHz**:
00349 * ```
00350 * Period = PCLKA / PWM_freq = 120,000,000 / 20,000 = 6000 counts
00351 * Resolution = 100% / 6000 = 0.0167% per count
00352 * Voltage resolution (12V supply) = 12V x 0.0167% = 2 mV per step
00353 * ```
00354 *
00355 * **Encoder Capture Precision**:
00356 * ```
00357 * Max velocity = 2.5 m/s (STAR robot spec)
00358 * Wheel diameter = 0.1 m -> circumference = 0.314 m
00359 * Max RPM = (2.5 m/s / 0.314 m) x 60 = 477 RPM
00360 * Encoder PPR = 341 x 4 (quadrature) = 1364 edges/rev
00361 * Max edge rate = 477 RPM x 1364 edges / 60 = 10,836 edges/sec
00362 * Min edge period = 1 / 10,836 = 92.3 us
00363 * Timer counts per edge @ 120 MHz = 92.3 us x 120 MHz = 11,076 counts
00364 * Velocity resolution = 1 count / 11,076 = 0.009% per timer count [OK]
00365 * ```
00366 *
00367 * **Rationale**: 120 MHz chosen for:
00368 * - PWM resolution: 6000 steps @ 20 kHz (excellent granularity)
00369 * - Encoder precision: 0.009% velocity measurement resolution
00370 * - Timer headroom: Max edge rate only uses 10% of timer bandwidth
00371 *
00372 * @par Impact of Changing:
00373 * - **Increase to 240 MHz**: Double PWM resolution (12000 steps), but wastes power
00374 * - **Decrease to 60 MHz**: Half PWM resolution (3000 steps), still acceptable
00375 *
00376 * @warning GPT, MTU, CMT baud rate calculations assume 120 MHz. Changing PCLKA
00377 * requires recalculating all timer prescalers and compare values.
00378 */

00382 * @brief Peripheral Clock B (PCLKB) - 60 MHz
00383 *
00384 * @details
00385 * Standard-speed peripheral clock for communication interfaces: UART serial
00386 * console, SPI to Raspberry Pi 5, and I2C sensor bus.
00387 *
00388 * **Value**: 60,000,000 Hz (60 MHz)
00389 * **Source**: ICLK (240 MHz) divided by 4
00390 * **Cycle time**: 16.67 nanoseconds per cycle
00391 * **Register**: SYSTEM.SCKCR.PCKB (divider = b'0010' = /4 from ICLK)
00392 *
00393 * **Connected Peripherals**:
00394 * - **SCI (Serial Communication Interface)**: UART for USB CDC debug console
00395 * - **RSPI (Renesas SPI)**: SPI controller for RPi5 communication
00396 * - **RIIC (Renesas I2C)**: I2C controller for sensor bus (IMU, lidar interface)
00397 *
00398 * **Baud Rate Capabilities**:
00399 *
00400 * **UART (SCI) @ 115200 baud**:
00401 * ```
00402 * BRR = (PCLKB / (32 x baud_rate)) - 1
00403 * BRR = (60,000,000 / (32 x 115200)) - 1 = 16.276... ~ 16
00404 * Actual baud = 60,000,000 / (32 x 17) = 110,294 baud
00405 * Error = (110,294 - 115200) / 115200 = -4.3% (within +/-5% tolerance) [OK]
00406 * ```
00407 *
00408 * **SPI (RSPI) @ 10 Mbps** (STAR project: communication with RPi5):
00409 * ```
00410 * SPI_bitrate = PCLKB / (2 x (SPBR + 1))
00411 * 10 Mbps = 60,000,000 / (2 x (SPBR + 1))
00412 * SPBR = (60,000,000 / (2 x 10,000,000)) - 1 = 2
00413 * Actual rate = 60,000,000 / (2 x 3) = 10 Mbps exact [OK]

```

```

00414 * ````
00415 *
00416 * **I2C (RIIC) @ 400 kHz** (Fast-mode I2C for IMU):
00417 * ````
00418 * I2C_freq = PCLKB / (CKS x (BRL + BRH + 4))
00419 * 400 kHz typical with CKS=0 (prescaler /1), BRL=BRH=73
00420 * Actual = 60,000,000 / (1 x (73 + 73 + 4)) = 400 kHz exact [OK]
00421 * ````
00422 *
00423 * **Rationale**: 60 MHz chosen for:
00424 * - UART: Standard baud rates (9600, 19200, 115200) achievable with <5% error
00425 * - SPI: 10 Mbps target rate (STAR requirement) achievable exactly
00426 * - I2C: 100 kHz (standard) and 400 kHz (fast-mode) both supported
00427 * - Power: Lower clock = lower power for communication peripherals
00428 *
00429 * @par Impact of Changing:
00430 * - **Increase to 120 MHz**: Would allow 20 Mbps SPI, but RPi5 limited to 10 Mbps
00431 * - **Decrease to 30 MHz**: Would limit SPI to 5 Mbps, still acceptable
00432 *
00433 * @warning All UART/SPI/I2C drivers assume 60 MHz PCLKB. Changing requires
00434 * recalculating all BRR/SPBR register values.
00435 */

00496 * @brief External Bus Clock (BCLK) - 120 MHz (unused in STAR project)
00497 *
00498 * @details
00499 * Clock for external memory interface (SDRAM, SRAM, NOR flash). Not used in
00500 * STAR project as all code/data fits in internal 4MB flash + 512KB SRAM.

```

```

00501 *
00502 * **Value**: 120,000,000 Hz (120 MHz)
00503 * **Source**: ICLK (240 MHz) divided by 2
00504 * **Register**: SYSTEM.SCKCR.BCK (divider = b'0001' = /2 from ICLK)
00505 *
00506 * **Rationale**: Configured to 120 MHz despite being unused because:
00507 * - Default safe value (does not affect internal operation)
00508 * - Matches PCLKA (high-speed peripheral clock)
00509 * - Future-proofing if external memory added later
00510 *
00511 * @warning Not used in STAR (no external bus devices). Changing has no effect.
00512 */
00513 k_bclk_hz = 120000000UL,
00514
00515 /**
00516 * @brief Flash Memory Clock (FCLK) - 60 MHz (hardware limit)
00517 *
00518 * @details
00519 * Clock for internal flash controller (code fetch, const data access). This
00520 * frequency MUST NOT EXCEED 60 MHz per RX72N datasheet, regardless of CPU
00521 * clock speed.
00522 *
00523 * **Value**: 60,000,000 Hz (60 MHz)
00524 * **Source**: ICLK (240 MHz) divided by 4
00525 * **Cycle time**: 16.67 nanoseconds per cycle
00526 * **Register**: SYSTEM.SCKCR.FCK (divider = b'0010' = /4 from ICLK)
00527 *
00528 * **Flash Access Characteristics**:
00529 * - **1-wait access**: 16.67 ns + wait state ~ 20 ns per access
00530 * - **CPU cycles per access**: 20 ns / 4.17 ns = ~5 CPU cycles
00531 * - **Code throughput**: ~48 million instructions/sec (if 1 fetch per instruction)
00532 * - **Actual throughput**: Higher due to caching and instruction pipelining
00533 *
00534 * **Wait State Configuration** (FACI.FWEPROR register):
00535 * ```
00536 * ICLK = 240 MHz, FCLK = 60 MHz
00537 * Wait states = 1 (minimum for 60 MHz FCLK @ 240 MHz ICLK)
00538 * Access time = 1 FCLK cycle + 1 wait = 33.3 ns
00539 * ```
00540 *
00541 * **Performance Impact**:
00542 * - Flash access is slower than SRAM (5 cycles vs 1 cycle)
00543 * - Critical loops should use SRAM ('__attribute__((section(".data"))')
00544 * - Const data in flash adds latency vs SRAM variables
00545 *
00546 * **Rationale**: 60 MHz is MAXIMUM allowed by hardware:
00547 * - Exceeding 60 MHz causes flash corruption and data loss
00548 * - Lower frequencies (30 MHz) would reduce throughput unnecessarily
00549 * - 60 MHz balances speed and hardware safety limit
00550 *
00551 * @par Impact of Changing:
00552 * - **Increase >60 MHz**: **FORBIDDEN** - Violates datasheet, causes corruption
00553 * - **Decrease to 30 MHz**: Halves flash throughput, increases code execution time
00554 *
00555 * @warning **CRITICAL**: FCLK MUST NOT EXCEED 60 MHz under any circumstances.
00556 * Flash controller will malfunction if overclocked, leading to data
00557 * corruption, crashes, and potential permanent flash damage.
00558 *
00559 * @attention If increasing ICLK in future, MUST adjust FCK divider to keep
00560 * FCLK <=60 MHz. Example: ICLK=480 MHz requires FCK divider /8.

Get pointer to CMT Unit 1 control register (CMSTR1).

### 8.9.1 Detailed Description

#### RX72N Compare Match Timer (CMT) Register Definitions.

Register definitions for the Compare Match Timer (CMT) peripheral on the RX72N microcontroller. CMT provides simple periodic interrupt generation used for RTOS system tick and general timing purposes.

#### CMT System Architecture

Memory Map (Verified against RX72N Manual Ch31):

| Address    | Register                               |
|------------|----------------------------------------|
| 0x00088000 | CMSTR0 (Start Register Unit 0: CMT0/1) |
| 0x00088002 | CMT0.CMCR (Control Register)           |
| 0x00088004 | CMT0.CMCNT (Counter)                   |
| 0x00088006 | CMT0.CMCOR (Compare Match Register)    |
| 0x00088008 | CMT1.CMCR                              |
| 0x0008800A | CMT1.CMCNT                             |
| 0x0008800C | CMT1.CMCOR                             |
| 0x00088010 | CMSTR1 (Start Register Unit 1: CMT2/3) |
| 0x00088012 | CMT2.CMCR                              |
| 0x00088014 | CMT2.CMCNT                             |
| 0x00088016 | CMT2.CMCOR                             |
| 0x00088018 | CMT3.CMCR                              |
| 0x0008801A | CMT3.CMCNT                             |
| 0x0008801C | CMT3.CMCOR                             |

### Timer Period Calculation

The CMT generates an interrupt when CMCNT matches CMCOR. The timer period is calculated as:

$$T_{period} = \frac{(CMCOR + 1) \times DIV}{f_{PCLKB}}$$

Where:

- $T_{period}$  = Timer period in seconds
- $CMCOR$  = Compare match register value (0-65535)
- $DIV$  = Clock divider (8, 32, 128, or 512)
- $f_{PCLKB}$  = Peripheral clock B frequency (60 MHz)

### STAR Project ThreadX Configuration (100 Hz tick)

$$CMCOR = \frac{f_{PCLKB}}{DIV \times f_{tick}} - 1 = \frac{60,000,000}{32 \times 100} - 1 = 18,749$$

Note: PCLKB/8 cannot reach 100 Hz – it requires CMCOR=74999 which exceeds the 16-bit register maximum of 65535. Use PCLKB/32 (CKS=01) for exact 100 Hz.

Example: CMT0 Initialization for 100 Hz ThreadX Tick

```
#include "rx72n_cmt_regs.h"

// Stop CMT0 before configuration
cmt_ctrl()->cmstr0 &= ~k_rx72n_cmstr0_cmt0_enable;

// Configure CMT0: PCLKB/32 = 1.875 MHz, interrupt enable, reserved bit7=1
cmt0()->cmcr = 0x00C1; // CKS=01 (PCLKB/32), CMIE=1, bit7=1(rsvd)

// Set compare match value for 100 Hz: 1.875 MHz / 100 - 1 = 18749
cmt0()->cmcor = 18749;

// Clear counter
cmt0()->cmcnt = 0;

// Configure interrupt in ICU (priority 5, vector 28)
// ... (see rx72n_icu_regs.h for ICU configuration)

// Start CMT0
cmt_ctrl()->cmstr0 |= k_rx72n_cmstr0_cmt0_enable;
```

### NASA Power of 10 Compliance

- Rule 3: No dynamic memory - all register access via static inline functions
- Rule 5: Compile-time assertions verify all register layout assumptions
- Rule 8: Uses typed enums (C23) for all constants, no magic numbers
- Rule 10: Clean build with -Wall -Wextra -Werror

### SOLID Principles

- Single Responsibility: CMT register definitions only, no driver logic
- Open/Closed: Accessors can be used with any CMT configuration
- Interface Segregation: Minimal API - just register access functions

## Manual Reference

RX72N Group User's Manual: Hardware, Chapter 31 (Compare Match Timer)

## Verification Status

[PASS] VERIFIED (2026-01-28) - All register addresses and offsets verified against RX72N Manual Chapter 31.

00071 *
00072 * @par Timer Period Calculation
00073 * The CMT generates an interrupt when CMCNT matches CMCOR. The timer period
00074 * is calculated as:
00075 *
00076 * @f[
00077 * T_{period} = \frac{(CMCOR + 1) \times DIV}{f_{PCLKB}}
00078 * @f]
00079 *
00080 * Where:
00081 * - @f$ T_{period} @f$ = Timer period in seconds
00082 * - @f$ CMCOR @f$ = Compare match register value (0-65535)
00083 * - @f$ DIV @f$ = Clock divider (8, 32, 128, or 512)
00084 * - @f$ f_{PCLKB} @f$ = Peripheral clock B frequency (60 MHz)
00085 *
00086 * @par STAR Project ThreadX Configuration (100 Hz tick)
00087 * @f[
00088 * CMCOR = \frac{f_{PCLKB}}{DIV \times f_{tick}} - 1
00089 * = \frac{60,000,000}{32 \times 100} - 1 = 18,749
00090 * @f]
00091 *
00092 * Note: PCLKB/8 cannot reach 100 Hz -- it requires CMCOR=74999 which exceeds the
00093 * 16-bit register maximum of 65535. Use PCLKB/32 (CKS=01) for exact 100 Hz.
00094 *
00095 * @par Example: CMT0 Initialization for 100 Hz ThreadX Tick
00096 * @code
00097 * #include "rx72n_cmt_regs.h"
00098 *
00099 * // Stop CMT0 before configuration
00100 * cmt_ctrl()->cmstr0 &= ~k_rx72n_cmstr0_cmt0_enable;
00101 *
00102 * // Configure CMT0: PCLKB/32 = 1.875 MHz, interrupt enable, reserved bit7=1
00103 * cmt0()->cmcr = 0x00C1; // CKS=01 (PCLKB/32), CMIE=1, bit7=1(rsvd)
00104 *
00105 * // Set compare match value for 100 Hz: 1.875 MHz / 100 - 1 = 18749
00106 * cmt0()->cmcor = 18749;
00107 *
00108 * // Clear counter
00109 * cmt0()->cmcnt = 0;
00110 *

Get pointer to CRC registers.

## 8.11.1 Detailed Description

## RX72N CRC Calculator Register Definitions.

Register definitions for the hardware CRC Calculator used for CRC-32 acceleration. The CRC module provides hardware-accelerated cyclic redundancy check computation, significantly faster than software implementations.

## System Architecture

## STAR Project CRC Usage

| Use Case                 | Polynomial  | Direction | Notes                   |
|--------------------------|-------------|-----------|-------------------------|
| SPI Protocol (RPI5)      | CRC-32 IEEE | LSB-first | nanopb frame validation |
| Flash Integrity (future) | CRC-32 IEEE | MSB-first | Firmware verification   |

### Key Features

- Hardware-accelerated CRC calculation (single cycle per byte)
- CRC-32 IEEE 802.3 polynomial (0x04C11DB7) for compatibility with Go
- Configurable bit order (MSB-first or LSB-first/reflected)
- Direct memory-mapped register access
- Supports CRC-8, CRC-16, CRC-CCITT, CRC-32, CRC-32C (only CRC-32 used)

### CRC-32 IEEE 802.3 Specification

- Polynomial: 0x04C11DB7 (normal form)
- Initial Value: 0xFFFFFFFF
- Reflect Input: Yes (LSB-first in STAR project)
- Reflect Output: Yes
- Final XOR: 0xFFFFFFFF

### Performance

| Method       | Time for 64 bytes | Notes                       |
|--------------|-------------------|-----------------------------|
| Hardware CRC | ~64 cycles        | 1 cycle per byte @ 240 MHz  |
| Software CRC | ~2000+ cycles     | Table lookup method         |
| Speedup      | ~31x              | Critical for SPI throughput |

### Hardware Requirements

| Parameter    | Value           | Notes                      |
|--------------|-----------------|----------------------------|
| Base Address | 0x00088280      | 12-byte register block     |
| Module Stop  | MSTPCRB.MSTPB23 | Clear to enable module     |
| Clock        | PCLKB (60 MHz)  | No additional clock needed |

### NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion
- Rule 2: [OK] N/A (no loops in register definitions)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] All accessor functions are single-statement
- Rule 5: [OK] N/A (hardware layer)
- Rule 6: [OK] Minimal scope - inline accessors only
- Rule 7: [OK] N/A (no return values to check)
- Rule 8: [OK] All constants use C23 typed enums
- Rule 9: [OK] No function pointers
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

## SOLID Principles

- S: Single responsibility - only CRC register definitions
- O: Open for extension via additional polynomial support
- L: N/A (no inheritance hierarchy)
- I: Minimal interface - only necessary accessor
- D: N/A (hardware register layer)

## Module Dependencies

- `<stdint.h>` - Fixed-width integer types
- `<stddef.h>` - `offsetof` macro for static assertions

## Manual References

RX72N Group User's Manual: Hardware (R01UH0824EJ0120 Rev.1.20)

- Chapter 46: CRC Calculator, pages 2411-2420

## Compatibility

The CRC-32 IEEE 802.3 output is compatible with:

- Go: `crc32.ChecksumIEEE()`
- Python: `binascii.crc32()`
- Linux: `cksum -o 3`

## 8.11.2 Data Structure Documentation

### 8.11.2.1 struct rx\_crc\_regs\_t

CRC Calculator Register Map Structure.

Hardware CRC Calculator registers for accelerated CRC computation. The CRC module computes CRC checksums in hardware, significantly faster than software implementations.

Memory Layout Table

| Offset | Size | Field    | Type          | Description          |
|--------|------|----------|---------------|----------------------|
| 0x00   | 1    | crccr    | uint8↔<br>_t  | Control Register     |
| 0x01   | 3    | reserved | -             | Reserved             |
| 0x04   | 4    | crkdir   | uint32↔<br>_t | Data Input Register  |
| 0x08   | 4    | crcdor   | uint32↔<br>_t | Data Output Register |
| Total  | 12   |          |               |                      |

### CRC Calculation Process

1. Configure CRCCR with polynomial and bit order
2. Clear the output register by writing DORCLR=1
3. Feed data bytes/words to CRCDIR
4. Read final CRC from CRCDOR

### Initialization Example (CRC-32 IEEE)

```
// Configure CRC-32 IEEE 802.3 with LSB-first (reflected) mode
volatile rx_crc_regs_t* crc = crc_regs();

// 1. Set polynomial to CRC-32 IEEE, LSB-first
crc->crccr = k_crc_crccr_gps_crc32 | k_crc_crccr_lms;

// 2. Clear output register (initialize to 0xFFFFFFFF)
crc->crccr |= k_crc_crccr_dorclr;

// 3. Feed data (example: 4 bytes)
crc->crkdir = 0x12345678; // Feed 4 bytes at once

// 4. Read result
uint32_t crc_result = crc->crcdor;
```

### Byte-by-Byte Example

```
// Calculate CRC of a buffer
uint32_t calculate_crc32(const uint8_t* data, uint32_t len) {
 volatile rx_crc_regs_t* crc = crc_regs();

 // Configure for CRC-32 IEEE, LSB-first
 crc->crccr = k_crc_crccr_gps_crc32 | k_crc_crccr_lms | k_crc_crccr_dorclr;

 // Feed data byte by byte
 for (uint32_t i = 0; i < len; i++) {
 ((volatile uint8_t)&crc->crkdir) = data[i];
 }

 // Return CRC (XOR with 0xFFFFFFFF for IEEE compliance)
 return crc->crcdor ^ 0xFFFFFFFF;
}
```

## Invariant

`sizeof(rx_crc_regs_t) == 12 bytes`  
All offsets match RX72N Hardware Manual Ch46

## Note

Hardware automatically processes each byte written to CRCDIR

## Warning

Must clear CRCDOR (DORCLR) before starting new calculation

## Attention

CRC module must be enabled in MSTPCRB before use

### 8.11.3 Enumeration Type Documentation

#### 8.11.3.1 rx\_crc\_addresses\_t

enum [rx\\_crc\\_addresses\\_t](#) : uintptr\_t

CRC module base address.

Base address for the CRC Calculator register block. The CRC module provides hardware-accelerated CRC computation with configurable polynomials.

#### Memory Map

| Address    | Register | Size | Description          |
|------------|----------|------|----------------------|
| 0x00088280 | CRCCR    | 1    | Control Register     |
| 0x00088281 | Reserved | 3    | -                    |
| 0x00088284 | CRCDIR   | 4    | Data Input Register  |
| 0x00088288 | CRCDOR   | 4    | Data Output Register |

00155 } rx_crc_addresses_t;

```

### 8.11.3.2 rx\_crc\_crccr\_bits\_t

```
enum rx_crc_crccr_bits_t : uint8_t
```

CRC Control Register (CRCCR) Bit Definitions.

Configuration values for CRC polynomial selection and bit order. Only CRC-32 IEEE 802.3 is used in the STAR project.

Generator Polynomial Select (GPS) Values

| GPS  | Polynomial       | Name        | Used in STAR |
|------|------------------|-------------|--------------|
| 0x00 | $X^8 + \dots$    | CRC-8       | No           |
| 0x01 | $X^{16} + \dots$ | CRC-16      | No           |
| 0x02 | $X^{16} + \dots$ | CRC-CCITT   | No           |
| 0x03 | 0x04C11DB7       | CRC-32 IEEE | Yes          |
| 0x04 | 0x1EDC6F41       | CRC-32C     | No           |

Bit Order Selection (LMS)

- MSB-first (LMS=0): Standard CRC, data processed from bit 7 to bit 0
- LSB-first (LMS=1): Reflected CRC, data processed from bit 0 to bit 7

For IEEE 802.3 compatibility (Go `crc32.ChecksumIEEE`), use LSB-first.

Configuration Example

```

// CRC-32 IEEE 802.3, LSB-first (reflected), clear output
crc_regs()->crccr = k_crc_crccr_gps_crc32 | k_crc_crccr_lms | k_crc_crccr_dorclr;

```

```

## 8.11.4 Function Documentation

### 8.11.4.1 crc\_regs()

volatile [rx\\_crc\\_regs\\_t](#) \* [crc\\_regs](#) (  
void ) [inline], [static]

Get pointer to CRC registers.

Returns a volatile pointer to the CRC Calculator register structure at address 0x00088280. The CRC module provides hardware-accelerated CRC computation for protocol integrity checking.

Returns

Volatile pointer to CRC register structure

Return values

|          |                                                 |
|----------|-------------------------------------------------|
| Non-NULL | Always returns valid pointer (hardware address) |
|----------|-------------------------------------------------|

Precondition

CRC module must be enabled (MSTPCRB.MSTPB23 = 0)

Postcondition

Pointer is valid for the lifetime of program execution

## Note

Thread Safety: Safe - returns constant hardware address

This function is always inlined for zero overhead

## Warning

Ensure module stop bit is cleared before accessing registers

## Example:

```
// Quick CRC calculation
volatile rx_crc_regs_t* crc = crc_regs();
crc->cccr = k_crc_cccr_gps_crc32 | k_crc_cccr_lms | k_crc_cccr_dorclr;
crc->credir = data_word;
uint32_t result = crc->credor ^ 0xFFFFFFFF;
```

## Functions

- static volatile [rx\\_dmac\\_channel\\_regs\\_t](#) \* [dmac\\_channel](#) ([uint8\\_t](#) channel)  
Get pointer to DMAC channel registers.
- static volatile [rx\\_dmac\\_channel\\_regs\\_t](#) \* [dmac0](#) (void)  
Get pointer to DMAC channel 0 registers.
- static volatile [rx\\_dmac\\_channel\\_regs\\_t](#) \* [dmac1](#) (void)  
Get pointer to DMAC channel 1 registers.
- static volatile [rx\\_dmac\\_channel\\_regs\\_t](#) \* [dmac2](#) (void)  
Get pointer to DMAC channel 2 registers.
- static volatile [rx\\_dmac\\_channel\\_regs\\_t](#) \* [dmac3](#) (void)  
Get pointer to DMAC channel 3 registers.
- static volatile [rx\\_dmac\\_channel\\_regs\\_t](#) \* [dmac4](#) (void)  
Get pointer to DMAC channel 4 registers.
- static volatile [rx\\_dmac\\_channel\\_regs\\_t](#) \* [dmac5](#) (void)  
Get pointer to DMAC channel 5 registers.
- static volatile [rx\\_dmac\\_channel\\_regs\\_t](#) \* [dmac6](#) (void)  
Get pointer to DMAC channel 6 registers.
- static volatile [rx\\_dmac\\_channel\\_regs\\_t](#) \* [dmac7](#) (void)  
Get pointer to DMAC channel 7 registers.
- static volatile [uint8\\_t](#) \* [dmac\\_dmast\\_reg](#) (void)  
Get pointer to DMAC Module Start Register (DMAST).
- static volatile [uint8\\_t](#) \* [dmac\\_dmist\\_reg](#) (void)  
Get pointer to DMAC74 Interrupt Status Monitor Register (DMIST).

### 8.13.1 Detailed Description

#### RX72N DMA Controller (DMAC) Register Definitions.

Complete register definitions for the RX72N 8-channel DMA Controller. The DMAC transfers data without CPU intervention, supporting normal, repeat, and block transfer modes.

#### DMAC Overview

- 8 independent channels (DMAC0-DMAC7)
- 512 MB transfer space (0x00000000-0xFFFFFFFF, 0xF0000000-0xFFFFFFFF)
- Maximum 64M data transfers (1024 data x 65536 blocks)
- 8/16/32-bit transfer sizes
- Software or peripheral interrupt triggers
- Channel priority: Ch0 > Ch1 > Ch2 > ... > Ch7

#### Register Organization

| Address    | Size | Description                      |
|------------|------|----------------------------------|
| 0x00082000 | -    | DMAC channel 0 base              |
| 0x00082040 | -    | DMAC channel 1 base              |
| ...        | ...  | (channels spaced 0x40 apart)     |
| 0x000821C0 | -    | DMAC channel 7 base              |
| 0x00082200 | 8    | DMAST - Module Start Register    |
| 0x00082204 | 8    | DMIST - Interrupt Status Monitor |

#### Per-Channel Register Offsets

| Offset | Size | Register | Description                 |
|--------|------|----------|-----------------------------|
| 0x00   | 32   | DMSAR    | Source Address              |
| 0x04   | 32   | DMDAR    | Destination Address         |
| 0x08   | 32   | DMCRA    | Transfer Count A            |
| 0x0C   | 16   | DMCRB    | Transfer Count B            |
| 0x10   | 16   | DMTMD    | Transfer Mode               |

## NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: N/A (no loops)
- Rule 3: No dynamic memory allocation
- Rule 4: Short accessor functions
- Rule 5: Static assertions verify addresses
- Rule 6: Minimal scope
- Rule 7: N/A
- Rule 8: All constants use C23 typed enums
- Rule 9: No function pointers
- Rule 10: Compiles with -Wall -Wextra -Werror

## 8.13.2 Data Structure Documentation

### 8.13.2.1 struct rx\_dmac\_channel\_regs\_t

DMAC per-channel register structure.

Memory-mapped register layout for one DMAC channel. Each channel has 64 bytes (0x40) of register space.

## Warning

DMOFR register at offset 0x18 is ONLY valid for channel 0! For channels 1-7, this location is reserved.

## Note

Structure size verified as 0x20 (32 bytes of active registers) with reserved padding to fill 0x40 channel spacing.

00581 } dmist_bits_t;

```

### 8.13.3.11 dmreq\_bits\_t

```
enum dmreq_bits_t : uint8_t
```

DMA Software Start Register (DMREQ) bit definitions.

Register Layout (8-bit @ offset 0x1D)

| Bit      | Field | Description                  |
|----------|-------|------------------------------|
| 0        | SWREQ | DMA Software Start           |
| 3:↵<br>1 | -     | Reserved                     |
| 4        | CLRS  | DMA Software Start Bit Clear |
| 7:↵<br>5 | -     | Reserved                     |

Note

Manual ref: Ch18 section 18.2.10

Since

Version 1.0.0

Enumerator

|               |                                       |
|---------------|---------------------------------------|
| k_dmreq_swreq | Software start (write 1 to trigger)   |
| k_dmreq_clrs  | Auto-clear SWREQ after transfer start |

Definition at line 479 of file rx72n\_dmac\_regs.h.

```
00479 : uint8_t {
00480 k_dmreq_swreq = 0x01U, /**< Software start (write 1 to trigger) */
00481 k_dmreq_clrs = 0x10U, /**< Auto-clear SWREQ after transfer start */
00482 } dmreq_bits_t;
```

### 8.13.3.12 dmsts\_bits\_t

```
enum dmsts_bits_t : uint8_t
```

DMA Status Register (DMSTS) bit definitions.

Register Layout (8-bit @ offset 0x1E)

| Bit      | Field | Description              |
|----------|-------|--------------------------|
| 0        | ESIF  | Transfer Escape End Flag |
| 3:↵<br>1 | -     | Reserved                 |
| 4        | DTIF  | Transfer End Flag        |
| 6:↵<br>5 | -     | Reserved                 |
| 7        | ACT   | DMA Active Flag          |

Note

Manual ref: Ch18 section 18.2.11

Since

Version 1.0.0

Enumerator

|              |                                          |
|--------------|------------------------------------------|
| k_dmsts_esif | Transfer escape end flag                 |
| k_dmsts_dtif | Transfer end flag                        |
| k_dmsts_act  | DMA active flag (1=transfer in progress) |

Definition at line 505 of file [rx72n\\_dmac\\_regs.h](#).

```

00505 : uint8_t {
00506 k_dmsts_esif = 0x01U, /**< Transfer escape end flag */

## 8.13.4 Function Documentation

### 8.13.4.1 dmac0()

```
volatile rx_dmac_channel_regs_t * dmac0 (
 void) [inline], [static]
```

Get pointer to DMAC channel 0 registers.

Returns

Volatile pointer to DMAC0 register structure

Since

Version 1.0.0

Definition at line 649 of file [rx72n\\_dmac\\_regs.h](#).

```
00650 {
00651 return (volatile rx_dmac_channel_regs_t*)k_dmac0_base_addr;
00652 }
```

References [k\\_dmac0\\_base\\_addr](#).

### 8.13.4.2 dmac1()

```
volatile rx_dmac_channel_regs_t * dmac1 (
 void) [inline], [static]
```

Get pointer to DMAC channel 1 registers.

Returns

Volatile pointer to DMAC1 register structure

Since

Version 1.0.0

Definition at line 659 of file [rx72n\\_dmac\\_regs.h](#).

```
00660 {
00661 return (volatile rx_dmac_channel_regs_t*)k_dmac1_base_addr;
00662 }
```

References [k\\_dmac1\\_base\\_addr](#).

#### 8.13.4.3 dmac2()

```
volatile rx_dmac_channel_regs_t * dmac2 (
 void) [inline], [static]
```

Get pointer to DMAC channel 2 registers.

Returns

Volatile pointer to DMAC2 register structure

Since

Version 1.0.0

Definition at line 669 of file [rx72n\\_dmac\\_regs.h](#).

```
00670 {
00671 return (volatile rx_dmac_channel_regs_t*)k_dmac2_base_addr;
00672 }
```

References [k\\_dmac2\\_base\\_addr](#).

#### 8.13.4.4 dmac3()

```
volatile rx_dmac_channel_regs_t * dmac3 (
 void) [inline], [static]
```

Get pointer to DMAC channel 3 registers.

Returns

Volatile pointer to DMAC3 register structure

Since

Version 1.0.0

Definition at line 679 of file [rx72n\\_dmac\\_regs.h](#).

```
00680 {
00681 return (volatile rx_dmac_channel_regs_t*)k_dmac3_base_addr;
00682 }
```

References [k\\_dmac3\\_base\\_addr](#).

#### 8.13.4.5 dmac4()

```
volatile rx_dmac_channel_regs_t * dmac4 (
 void) [inline], [static]
```

Get pointer to DMAC channel 4 registers.

Returns

Volatile pointer to DMAC4 register structure

Since

Version 1.0.0

Definition at line 689 of file [rx72n\\_dmac\\_regs.h](#).

```
00690 {
00691 return (volatile rx_dmac_channel_regs_t*)k_dmac4_base_addr;
00692 }
```

References [k\\_dmac4\\_base\\_addr](#).

#### 8.13.4.6 dmac5()

```
volatile rx_dmac_channel_regs_t * dmac5 (
 void) [inline], [static]
```

Get pointer to DMAC channel 5 registers.

Returns

Volatile pointer to DMAC5 register structure

Since

Version 1.0.0

Definition at line 699 of file [rx72n\\_dmac\\_regs.h](#).

```
00700 {
00701 return (volatile rx_dmac_channel_regs_t*)k_dmac5_base_addr;
00702 }
```

References [k\\_dmac5\\_base\\_addr](#).

#### 8.13.4.7 dmac6()

```
volatile rx_dmac_channel_regs_t * dmac6 (
 void) [inline], [static]
```

Get pointer to DMAC channel 6 registers.

Returns

Volatile pointer to DMAC6 register structure

Since

Version 1.0.0

Definition at line 709 of file [rx72n\\_dmac\\_regs.h](#).

```
00710 {
00711 return (volatile rx_dmac_channel_regs_t*)k_dmac6_base_addr;
00712 }
```

References [k\\_dmac6\\_base\\_addr](#).

#### 8.13.4.8 dmac7()

```
volatile rx_dmac_channel_regs_t * dmac7 (
 void) [inline], [static]
```

Get pointer to DMAC channel 7 registers.

Returns

Volatile pointer to DMAC7 register structure

Since

Version 1.0.0

Definition at line 719 of file [rx72n\\_dmac\\_regs.h](#).

```
00720 {
00721 return (volatile rx_dmac_channel_regs_t*)k_dmac7_base_addr;
00722 }
```

References [k\\_dmac7\\_base\\_addr](#).

### 8.13.4.9 `dmac_channel()`

```
volatile rx_dmac_channel_regs_t * dmac_channel (
 uint8_t channel) [inline], [static]
```

Get pointer to DMAC channel registers.

#### Parameters

|         |                      |
|---------|----------------------|
| channel | Channel number (0-7) |
|---------|----------------------|

#### Returns

Volatile pointer to channel register structure

#### Precondition

channel < `k_dmac_channel_count` (8)

DMAC module stop bit (MSTPCRA.MSTPA28) must be cleared

#### Note

Thread Safety: Safe - returns constant hardware address

#### Example:

```
// Configure channel 0 for memory-to-memory transfer
volatile rx_dmac_channel_regs_t* ch0 = dmac_channel(k_dmac_channel_0);
ch0->dmsar = (uint32_t)src_buffer;
ch0->dmdar = (uint32_t)dst_buffer;
ch0->dmcr = transfer_count;
ch0->dmtmd = k_dmtmd_md_normal | k_dmtmd_sz_32bit | k_dmtmd_dctg_software;
ch0->dmamd = k_dmamd_sm_increment | k_dmamd_dm_increment;
ch0->dmcnt = k_dmcnt_dte; // Enable transfer
```

#### Since

Version 1.0.0

Definition at line 639 of file `rx72n_dmac_regs.h`.

```
00640 {
00641 return (volatile rx_dmac_channel_regs_t*)(k_dmac_base_addr + (channel * k_dmac_channel_size));
00642 }
```

References `k_dmac_base_addr`, and `k_dmac_channel_size`.

#### 8.13.4.10 dmac\_dmast\_reg()

```
volatile uint8_t * dmac_dmast_reg (
 void) [inline], [static]
```

Get pointer to DMAC Module Start Register (DMAST).

Returns

Volatile pointer to DMAST register (8-bit)

Since

Version 1.0.0

Definition at line 729 of file [rx72n\\_dmac\\_regs.h](#).

```
00730 {
00731 return (volatile uint8_t*)k_dmac_dmast_addr;
00732 }
```

References [k\\_dmac\\_dmast\\_addr](#).

#### 8.13.4.11 dmac\_dmist\_reg()

```
volatile uint8_t * dmac_dmist_reg (
 void) [inline], [static]
```

Get pointer to DMAC74 Interrupt Status Monitor Register (DMIST).

Returns

Volatile pointer to DMIST register (8-bit)

Since

Version 1.0.0

Definition at line 739 of file [rx72n\\_dmac\\_regs.h](#).

```
00740 {
00741 return (volatile uint8_t*)k_dmac_dmist_addr;
00742 }
```

References [k\\_dmac\\_dmist\\_addr](#).

## 8.14 rx72n\_dmac\_regs.h

DOCR bit-field values.

## Functions

- static volatile `rx_doc_regs_t` \* `doc` (void)  
Get pointer to DOC register block.

## 8.15.1 Detailed Description

## RX72N DOC (Data Operation Circuit) Register Definitions.

Register definitions for the Data Operation Circuit (DOC) peripheral on the RX72N microcontroller. The DOC is a small fixed-function accelerator that performs one of four 16-bit operations on two operands:

| Mode<br>(OMS[1:0]) | Operation                                  | Flag trigger             |
|--------------------|--------------------------------------------|--------------------------|
| 00 (DCSEL=0)       | 16-bit compare (mismatch detection)        | DODIR != DODSR           |
| 00 (DCSEL=1)       | 16-bit compare (match detection)           | DODIR == DODSR           |
| 01                 | 16-bit addition (DODSR = DODSR + DODIR)    | Carry (result > 0xFFFF)  |
| 10                 | 16-bit subtraction (DODSR = DODSR - DODIR) | Borrow (result < 0x0000) |
| 11                 | Setting prohibited                         | N/A                      |

The DOC sets DOPCF whenever the configured condition occurs; DOPCF is read-only and must be cleared by writing 1 to DOPCFCL. An interrupt (GROUPBL0::DOPCI) can optionally be generated via DOPCIE.

## 8.15.1.1 Memory Map

| Offset | Size | Register | Access | Description                    |
|--------|------|----------|--------|--------------------------------|
| 0x00   | 1    | DOCR     | R/W    | DOC Control Register           |
| 0x01   | 1    | -        | -      | Reserved                       |
| 0x02   | 2    | DODIR    | R/W    | Data Input Register            |
| 0x04   | 2    | DODSR    | R/W    | Data Setting Register / Result |

## 8.15.1.2 DOCR Bit Layout (8-bit)

| Bit      | Field         | Access | Description                                    |
|----------|---------------|--------|------------------------------------------------|
| 1:↵<br>0 | OMS[1:↵<br>0] | R/W    | Operating Mode Select                          |
| 2        | DCSEL         | R/W    | Detection Condition Select (compare mode only) |
| 3        | -             | R      | Reserved (read as 0)                           |
| 4        | DOPCIE        | R/W    | DOPCI Interrupt Enable (1=enabled)             |
| 5        | DOPCF         | R      | DOPC Flag (1=condition occurred)               |
| 6        | DOPCFCL       | W1C    | DOPCF Clear (write 1 to clear DOPCF)           |
| 7        | -             | R      | Reserved (read as 0)                           |

## 8.15.1.3 Module Stop Bit

DOC is clock-gated via MSTPCRB.MSTPB6. The DOC module stop bit must be cleared (under PRCR.↵  
PRC1 unlock) before accessing any DOC register, or writes will be silently ignored.

## 8.15.1.4 Interrupt Source

DOC raises one interrupt request: GROUPBL0.DOPCI (vector 110, group bit 29). When DOPCIE=1, setting DOPCF triggers GROUPBL0.DOPCI.

## Manual Reference

RX72N Group User's Manual: Hardware (R01UH0824EJ0111)

- Chapter 59: Data Operation Circuit (DOC), pages 2969-2978
- Section 11.2.2 MSTPCRB: page 409 (DOC = MSTPB6)
- Section 14.4 Group Interrupt Request Sources: GROUPBL0.DOPCI at bit 29

## NASA Power of 10 Compliance

- Rule 1: No goto / setjmp / recursion (header-only data)
- Rule 2: N/A (no loops)
- Rule 3: No dynamic allocation
- Rule 4: Accessor is a single-statement inline function
- Rule 5: N/A (hardware layer; enforced by higher-level API)

- Rule 6: Minimal scope (no file-scope variables)
- Rule 7: N/A (no return values to check)
- Rule 8: All constants use C23 typed enums (uintptr\_t for addresses)
- Rule 9: No function pointers
- Rule 10: Compiles with -Wall -Wextra -Werror

## 8.15.2 Data Structure Documentation

### 8.15.2.1 struct rx`doc`regs`t

DOC register map structure.

Packed volatile structure mirroring the DOC memory-mapped register layout. Access via the [doc\(\)](#) accessor returns a pointer to this structure at k\_doc\_base\_addr.

Memory Layout (6 bytes total)

| Offset | Size | Field     | Type         | Description          |
|--------|------|-----------|--------------|----------------------|
| 0x00   | 1    | docr      | uint8↔<br>_t | DOC Control Register |
| 0x01   | 1    | reserved0 | -            | Reserved             |

| Offset | Size | Field | Type     | Description                    |
|--------|------|-------|----------|--------------------------------|
| 0x02   | 2    | dodir | uint16_t | Data Input Register            |
| 0x04   | 2    | dodsr | uint16_t | Data Setting / Result Register |

Invariant

```
sizeof(rx_doc_regs_t) == 6
```

All offsets match RX72N HW Manual Chapter 59 register table

### 8.15.3 Enumeration Type Documentation

#### 8.15.3.1 rx`doc`addresses`t

enum [rx\\_doc\\_addresses\\_t](#) : uintptr\_t

DOC register block base address.

Base address for the Data Operation Circuit register block at 0x0008B080. The DOC occupies a 6-byte register window (DOCR, reserved byte, DODIR, DODSR).

#### Manual Reference

RX72N HW Manual, Chapter 59 (Data Operation Circuit), Register address table, page 2969.

```

#### 8.15.3.2 rx`doc`docr`bits`t

enum [rx\\_doc\\_docr\\_bits\\_t](#) : uint8\_t

DOCR bit-field values.

Pre-shifted values for writing DOCR fields. Values may be bitwise-OR'd together except that OMS fields are mutually exclusive.

## DOCR Layout (8-bit)

| Bit     | Field   | Notes                                            |

00271 } rx_doc_docr_shifts_t;
```

8.15.3.4 rx`doc`mstpb`bits``t`

```
enum rx_doc_mstpb_bits_t : uint8_t
```

DOC module stop bit position in MSTPCRB.

The DOC peripheral is clock-gated by bit 6 of MSTPCRB (MSTPB6). Writing 0 to this bit (under PRCR.PRC1 unlock) enables DOC; writing 1 stops the module.

Manual Reference

RX72N HW Manual, Section 11.2.2 MSTPCRB, page 409: MSTPB6 = DOC.

Since

Version 1.0.0

```

## 8.15.4 Function Documentation

### 8.15.4.1 doc()

```
volatile rx_doc_regs_t * doc (
 void) [inline], [static]
```

Get pointer to DOC register block.

Returns a volatile pointer to the DOC register structure mapped at k\_doc\_base\_addr (0x0008B080).

Returns

Volatile pointer to DOC register structure (never nullptr)

Return values

|          |                                       |
|----------|---------------------------------------|
| Non-NULL | Always returns valid hardware pointer |
|----------|---------------------------------------|

Precondition

Caller must have cleared MSTPCRB.MSTPB6 before accessing any register

Postcondition

Pointer is valid for program lifetime (hardware address is constant)

## Note

Thread Safety: Safe (returns a constant hardware address)  
 Always inlined; zero overhead

## Example

```
doc()->docr = k_doc_oms_compare | k_doc_dtsel_match;
doc()->dodir = 0xCAFE;
doc()->dodsr = 0xCAFE; // triggers DOC operation
```

## 8.16 rx72n`doc`regs.h

[Go to the documentation of this file.](#)

```

00001 /**
00002 * @file rx72n`doc`regs.h
00003 * @brief RX72N DOC (Data Operation Circuit) Register Definitions
00004 *
00005 * @details
00006 * Register definitions for the Data Operation Circuit (DOC) peripheral on the
00007 * RX72N microcontroller. The DOC is a small fixed-function accelerator that
00008 * performs one of four 16-bit operations on two operands:
00009 *
00010 * | Mode (OMS[1:0]) | Operation | Flag trigger |
00011 * |-----|-----|-----|
00012 * | 00 (DCSEL=0) | 16-bit compare (mismatch detection) | DODIR != DODSR |
00013 * | 00 (DCSEL=1) | 16-bit compare (match detection) | DODIR == DODSR |
00014 * | 01 | 16-bit addition (DODSR = DODSR + DODIR) | Carry (result > 0xFFFF) |
00015 * | 10 | 16-bit subtraction (DODSR = DODSR - DODIR) | Borrow (result < 0x0000) |
00016 * | 11 | Setting prohibited | N/A |
00017 *
00018 * The DOC sets DOPCF whenever the configured condition occurs; DOPCF is read-only
00019 * and must be cleared by writing 1 to DOPCFCL. An interrupt (GROUPBL0::DOPCI) can
00020 * optionally be generated via DOPCIE.
00021 *
00022 * ## Memory Map
00023 *
00024 * | Offset | Size | Register | Access | Description |
00025 * |-----|-----|-----|-----|-----|
00026 * | 0x00 | 1 | DOCR | R/W | DOC Control Register |
00027 * | 0x01 | 1 | - | - | Reserved |
00028 * | 0x02 | 2 | DODIR | R/W | Data Input Register |
00029 * | 0x04 | 2 | DODSR | R/W | Data Setting Register / Result |
00030 *
00031 * ## DOCR Bit Layout (8-bit)
00032 *
00033 * | Bit | Field | Access | Description |
00034 * |-----|-----|-----|-----|
00035 * | 1:0 | OMS[1:0] | R/W | Operating Mode Select |
00036 * | 2 | DCSEL | R/W | Detection Condition Select (compare mode only) |
00037 * | 3 | - | R | Reserved (read as 0) |
00038 * | 4 | DOPCIE | R/W | DOPCI Interrupt Enable (1=enabled) |
00039 * | 5 | DOPCF | R | DOPC Flag (1=condition occurred) |
00040 * | 6 | DOPCFCL | W1C | DOPCF Clear (write 1 to clear DOPCF) |
00041 * | 7 | - | R | Reserved (read as 0) |
00042 *
00043 * ## Module Stop Bit
00044 *
00045 * DOC is clock-gated via MSTPCRB.MSTPB6. The DOC module stop bit must be
00046 * cleared (under PRCR.PRC1 unlock) before accessing any DOC register, or writes
00047 * will be silently ignored.
00048 *
00049 * ## Interrupt Source
00050 *
00051 * DOC raises one interrupt request: GROUPBL0.DOPCI (vector 110, group bit 29).
00052 * When DOPCIE=1, setting DOPCF triggers GROUPBL0.DOPCI.
00053 *

DTC module stop control bits.

## Functions

- static volatile `uint8_t` \* `dtc_dtccr_reg` (void)  
Get pointer to DTC Control Register (DTCCR).
- static volatile `uint32_t` \* `dtc_dtcvbr_reg` (void)

- Get pointer to DTC Vector Base Register (DTCVBR).
- static volatile uint8\_t \* [dtc\\_dtcadmod\\_reg](#) (void)
  - Get pointer to DTC Address Mode Register (DTCADMOD).
- static volatile uint8\_t \* [dtc\\_dtcst\\_reg](#) (void)
  - Get pointer to DTC Module Start Register (DTCST).
- static volatile uint16\_t \* [dtc\\_dtcsts\\_reg](#) (void)
  - Get pointer to DTC Status Register (DTCSTS).
- static volatile uint32\_t \* [dtc\\_dtcibr\\_reg](#) (void)
  - Get pointer to DTC Index Table Base Register (DTCIBR).
- static volatile uint8\_t \* [dtc\\_dtc\\_cor\\_reg](#) (void)
  - Get pointer to DTC Operation Register (DTCOR).
- static volatile uint16\_t \* [dtc\\_dtc\\_sqe\\_reg](#) (void)
  - Get pointer to DTC Sequence Transfer Enable Register (DTCSQE).
- static volatile uint32\_t \* [dtc\\_dtc\\_disp\\_reg](#) (void)
  - Get pointer to DTC Address Displacement Register (DTCDISP).

### 8.17.1 Detailed Description

RX72N Data Transfer Controller (DTCb) Register Definitions.

Complete register definitions for the RX72N Data Transfer Controller. The DTC performs interrupt-driven data transfers without CPU intervention, supporting normal, repeat, block, and sequence transfer modes.

#### DTC Overview

- Triggered by interrupt requests
- Number of channels = number of interrupt sources that can start DTC
- Transfer modes: normal, repeat, block, chain, sequence
- Transfer space: 16 MB (short) or 4 GB (full address mode)
- Single data sizes: 8/16/32-bit
- Block sizes: 1-256 data units
- Up to 256 sequences per trigger source

#### Register Organization

| Address    | Size | Register | Description                      |
|------------|------|----------|----------------------------------|
| 0x00082400 | 8    | DTCCR    | DTC Control Register             |
| 0x00082404 | 32   | DTCVBR   | DTC Vector Base Register         |
| 0x00082408 | 8    | DTCADMOD | DTC Address Mode Register        |
| 0x0008240C | 8    | DTCST    | DTC Module Start Register        |
| 0x0008240E | 16   | DTCSTS   | DTC Status Register              |
| 0x00082410 | 32   | DTCIBR   | DTC Index Table Base Register    |
| 0x00082414 | 8    | DTCOR    | DTC Operation Register           |
| 0x00082416 | 16   | DTCSQE   | DTC Sequence Transfer Enable Reg |

| Address    | Size | Register | Description                       |
|------------|------|----------|-----------------------------------|
| 0x00082418 | 32   | DTCDISP  | DTC Address Displacement Register |

#### DTC vs DMAC

- DTC: Low overhead, triggered by any interrupt, lightweight transfers
- DMAC: High throughput, dedicated 8 channels, advanced features
- DTC is ideal for small periodic transfers (ADC, UART, SPI)
- DMAC is better for bulk memory-to-memory transfers

#### NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: N/A (no loops)
- Rule 3: No dynamic memory allocation
- Rule 4: Short accessor functions
- Rule 5: Static assertions verify addresses
- Rule 6: Minimal scope
- Rule 7: N/A
- Rule 8: All constants use C23 typed enums
- Rule 9: No function pointers
- Rule 10: Compiles with -Wall -Wextra -Werror

## 8.17.3 Enumeration Type Documentation

### 8.17.3.1 dtc\_addresses\_t

```
enum dtc_addresses_t : uintptr_t
```

DTC module addresses.

Base address and individual register addresses for DTC control registers. All addresses verified against RX72N Hardware Manual Ch20.

Note

Addresses verified 2026-01-29 against manual section 20.2

Since

Version 1.0.0

```

#### 8.17.3.4 dtc\_mstpcr\_t

enum [dtc\\_mstpcr\\_t](#) : uint32\_t

DTC module stop control bits.

The DTC is controlled by MSTPCRA.MSTPA28. Must be cleared (0) before accessing DTC registers.

Note

Manual ref: Ch11 (Low Power Consumption) module stop tables

DTC and DMAC share the same module stop bit (MSTPA28)

00519 } dtc_mstpcr_t;
```

#### 8.17.3.5 dtc\_offsets\_t

enum [dtc\\_offsets\\_t](#) : uint8\_t

Register offsets from DTC base address.

Offsets for each register relative to [k\\_dtc\\_base\\_addr](#).

Note

Offsets verified 2026-01-29 against manual

Since

Version 1.0.0

Enumerator

|                       |                         |
|-----------------------|-------------------------|

## 8.17.4 Function Documentation

### 8.17.4.1 dtc\_dtcadmod\_reg()

```
volatile uint8_t * dtc_dtcadmod_reg (
 void) [inline], [static]
```

Get pointer to DTC Address Mode Register (DTCADMOD).

Returns

Volatile pointer to DTCADMOD register (8-bit)

Precondition

DTC module stop bit (MSTPCRA.MSTPA28) must be cleared

Since

Version 1.0.0

Definition at line 554 of file [rx72n\\_dtc\\_regs.h](#).

```

00555 {
00556 return (volatile uint8_t*)k_dtc_dtcadmod_addr;
00557 }

```

References [k\\_dtc\\_dtcadmod\\_addr](#).

#### 8.17.4.2 dtc\_dtccr\_reg()

```
volatile uint8_t * dtc_dtccr_reg (
 void) [inline], [static]
```

Get pointer to DTC Control Register (DTCCR).

Returns

Volatile pointer to DTCCR register (8-bit)

Precondition

DTC module stop bit (MSTPCRA.MSTPA28) must be cleared

Since

Version 1.0.0

Definition at line 532 of file [rx72n\\_dtc\\_regs.h](#).

```
00533 {
00534 return (volatile uint8_t*)k_dtc_dtccr_addr;
00535 }
```

References [k\\_dtc\\_dtccr\\_addr](#).

#### 8.17.4.3 dtc\_dtcdisp\_reg()

```
volatile uint32_t * dtc_dtcdisp_reg (
 void) [inline], [static]
```

Get pointer to DTC Address Displacement Register (DTCDISP).

Returns

Volatile pointer to DTCDISP register (32-bit)

Precondition

DTC module stop bit (MSTPCRA.MSTPA28) must be cleared

Since

Version 1.0.0

Definition at line 620 of file [rx72n\\_dtc\\_regs.h](#).

```
00621 {
00622 return (volatile uint32_t*)k_dtc_dtcdisp_addr;
00623 }
```

References [k\\_dtc\\_dtcdisp\\_addr](#).

#### 8.17.4.4 `dtc`dtcibr`reg()`

```
volatile uint32_t * dtc_dtcibr_reg (
 void) [inline], [static]
```

Get pointer to DTC Index Table Base Register (DTCIBR).

Returns

Volatile pointer to DTCIBR register (32-bit)

Precondition

DTC module stop bit (MSTPCRA.MSTPA28) must be cleared

Since

Version 1.0.0

Definition at line 587 of file [rx72n\\_dtc\\_regs.h](#).

```
00588 {
00589 return (volatile uint32_t*)k_dtc_dtcibr_addr;
00590 }
```

References [k\\_dtc\\_dtcibr\\_addr](#).

#### 8.17.4.5 `dtc`dtcor`reg()`

```
volatile uint8_t * dtc_dtcor_reg (
 void) [inline], [static]
```

Get pointer to DTC Operation Register (DTCOR).

Returns

Volatile pointer to DTCOR register (8-bit)

Precondition

DTC module stop bit (MSTPCRA.MSTPA28) must be cleared

Since

Version 1.0.0

Definition at line 598 of file [rx72n\\_dtc\\_regs.h](#).

```
00599 {
00600 return (volatile uint8_t*)k_dtc_dtcor_addr;
00601 }
```

References [k\\_dtc\\_dtcor\\_addr](#).

#### 8.17.4.6 dtc\_dtcseq\_reg()

```
volatile uint16_t * dtc_dtcseq_reg (
 void) [inline], [static]
```

Get pointer to DTC Sequence Transfer Enable Register (DTCSQE).

Returns

Volatile pointer to DTCSQE register (16-bit)

Precondition

DTC module stop bit (MSTPCRA.MSTPA28) must be cleared

Since

Version 1.0.0

Definition at line 609 of file [rx72n\\_dtc\\_regs.h](#).

```
00610 {
00611 return (volatile uint16_t*)k_dtc_dtcseq_addr;
00612 }
```

References [k\\_dtc\\_dtcseq\\_addr](#).

#### 8.17.4.7 dtc\_dtcst\_reg()

```
volatile uint8_t * dtc_dtcst_reg (
 void) [inline], [static]
```

Get pointer to DTC Module Start Register (DTCST).

Returns

Volatile pointer to DTCST register (8-bit)

Precondition

DTC module stop bit (MSTPCRA.MSTPA28) must be cleared

Since

Version 1.0.0

Definition at line 565 of file [rx72n\\_dtc\\_regs.h](#).

```
00566 {
00567 return (volatile uint8_t*)k_dtc_dtcst_addr;
00568 }
```

References [k\\_dtc\\_dtcst\\_addr](#).

#### 8.17.4.8 `dtc`dtcsts`reg()`

```
volatile uint16_t * dtc_dtcsts_reg (
 void) [inline], [static]
```

Get pointer to DTC Status Register (DTCSTS).

Returns

Volatile pointer to DTCSTS register (16-bit)

Precondition

DTC module stop bit (MSTPCRA.MSTPA28) must be cleared

Since

Version 1.0.0

Definition at line 576 of file [rx72n\\_dtc\\_regs.h](#).

```
00577 {
00578 return (volatile uint16_t*)k_dtc_dtcsts_addr;
00579 }
```

#### 8.17.4.9 `dtc`dtcvbr`reg()`

```
volatile uint32_t * dtc_dtcvbr_reg (
 void) [inline], [static]
```

Get pointer to DTC Vector Base Register (DTCVBR).

Returns

Volatile pointer to DTCVBR register (32-bit)

Precondition

DTC module stop bit (MSTPCRA.MSTPA28) must be cleared

Since

Version 1.0.0

Definition at line 543 of file [rx72n\\_dtc\\_regs.h](#).

```
00544 {
00545 return (volatile uint32_t*)k_dtc_dtcvbr_addr;
00546 }
```

00001 /**
00002 * @file rx72n_dtc_regs.h
00003 * @brief RX72N Data Transfer Controller (DTCb) Register Definitions
00004 *
00005 * @details
00006 * Complete register definitions for the RX72N Data Transfer Controller.
00007 * The DTC performs interrupt-driven data transfers without CPU intervention,
00008 * supporting normal, repeat, block, and sequence transfer modes.
00009 *
00010 * @par DTC Overview
00011 * - Triggered by interrupt requests
00012 * - Number of channels = number of interrupt sources that can start DTC
00013 * - Transfer modes: normal, repeat, block, chain, sequence
00014 * - Transfer space: 16 MB (short) or 4 GB (full address mode)
00015 * - Single data sizes: 8/16/32-bit
00016 * - Block sizes: 1-256 data units
00017 * - Up to 256 sequences per trigger source
00018 *
00019 * @par Register Organization
00020 * | Address | Size | Register | Description |
00021 * |-----|-----|-----|-----|
00022 * | 0x00082400 | 8 | DTCCR | DTC Control Register |
00023 * | 0x00082404 | 32 | DTCVBR | DTC Vector Base Register |
00024 * | 0x00082408 | 8 | DTCADMOD | DTC Address Mode Register |
00025 * | 0x0008240C | 8 | DTCST | DTC Module Start Register |
00026 * | 0x0008240E | 16 | DTCSTS | DTC Status Register |
00027 * | 0x00082410 | 32 | DTCIBR | DTC Index Table Base Register |
00028 * | 0x00082414 | 8 | DTCOR | DTC Operation Register |
00029 * | 0x00082416 | 16 | DTCSQE | DTC Sequence Transfer Enable Reg |
00030 * | 0x00082418 | 32 | DTCDISP | DTC Address Displacement Register |
00031 *
00032 * @par DTC vs DMAC
00033 * - DTC: Low overhead, triggered by any interrupt, lightweight transfers
00034 * - DMAC: High throughput, dedicated 8 channels, advanced features
00035 * - DTC is ideal for small periodic transfers (ADC, UART, SPI)
00036 * - DMAC is better for bulk memory-to-memory transfers
00037 *
00038 * @par NASA Power of 10 Compliance
00039 * - Rule 1: No goto, setjmp, or recursion
00040 * - Rule 2: N/A (no loops)
00041 * - Rule 3: No dynamic memory allocation
00042 * - Rule 4: Short accessor functions
00043 * - Rule 5: Static assertions verify addresses
00044 * - Rule 6: Minimal scope
00045 * - Rule 7: N/A
00046 * - Rule 8: All constants use C23 typed enums
00047 * - Rule 9: No function pointers
00048 * - Rule 10: Compiles with -Wall -Wextra -Werror
00049 *
00050 * @par Manual References
00051 * RX72N Group User's Manual: Hardware (R01UH0824EJ0120 Rev.1.20)

 MSTPCRC.MSTPC6 bit position for ECCRAM module-stop control.

## Functions

- static volatile [rx\\_eccram\\_regs\\_t](#) \* [eccram\\_regs](#) (void)  
Get pointer to the ECCRAM control register block.

### 8.19.1 Detailed Description

#### RX72N ECCRAM (ECC-protected RAM) Register Definitions.

Register definitions for the 32 KB ECC-protected RAM region on the RX72N. The ECCRAM supports Single-Error Correction / Double-Error Detection (SEC-DED) Hamming-style ECC over every aligned 32-bit word: one detected single-bit error is corrected on read, while any detected double-bit error raises an interrupt so that software can refuse to act on corrupt state (typically by e-stopping the system).

Memory Map (RX72N HW Manual Chapter 60, Table 60.1)

| Region | Start      | End        | Size  | Bus          |
|--------|------------|------------|-------|--------------|
| ECCRAM | 0x00FF8000 | 0x00FFFFFF | 32 KB | Memory Bus 3 |

Control Register Block (Manual Chapter 60, sections 60.2.9-60.2.17)

| Offset | Register     | Size | Description                                                              |
|--------|--------------|------|--------------------------------------------------------------------------|
| 0x00   | ECCRAMMODE   | 8    | ECC mode select<br>(disabled/correct/<br>correct-and-detect/detect-only) |
| 0x01   | ECCRAM2STS   | 8    | 2-bit error status flag                                                  |
| 0x02   | ECCRAM1STSEN | 8    | 1-bit error info update enable                                           |
| 0x03   | ECCRAM1STS   | 8    | 1-bit error status flag                                                  |
| 0x04   | ECCRAMPRCR   | 8    | Protection register (MODE/1STSEN)                                        |
| 0x08   | ECCRAM2ECAD  | 32   | 2-bit error address capture                                              |
| 0x0C   | ECCRAM1ECAD  | 32   | 1-bit error address capture                                              |
| 0x10   | ECCRAMPRCR2  | 8    | Protection register 2 (ETST)                                             |
| 0x14   | ECCRAMETST   | 8    | Test control (ECC decoder bypass)                                        |

Initialization Sequence (Manual section 60.3.3)

Before enabling error checking, every 32-bit word of ECCRAM must be written so that the ECC syndrome matches the data. Uninitialized ECC bits are random and would falsely flag errors on first read. The driver zeroes the entire region using 32-bit stores while the mode is set to `k_rx_eccrammode_ecc_no_check`, then switches to the final mode.

## NASA Power of 10 Compliance

- Rule 5: Static assertions verify all register offsets and base addresses
- Rule 8: All constants use C23 typed enums, no macros for numeric values
- Rule 9: Inline accessor (single-level pointer return), no function pointers

## Terminology

ECC = Error Correcting Code SEC-DED = Single Error Correction, Double Error Detection PRCR = Protection Register

## 8.19.2 Data Structure Documentation

### 8.19.2.1 struct rx\_eccram\_regs\_t

ECCRAM control register block.

Memory-mapped layout of the ECCRAM control registers starting at `k_rx_eccram_reg_base_addr` (0x000812C0). Reserved gaps preserve the hardware layout exactly as described in the manual.

## Invariant

`sizeof(rx_eccram_regs_t) == 24` bytes (21 documented + 3 tail padding)

All field offsets match RX72N HW Manual Chapter 60, sections 60.2.9-60.2.17

## See also

### 8.19.3 Enumeration Type Documentation

#### 8.19.3.1 rx'eccram1sts'bits't

```
enum rx_eccram1sts_bits_t : uint8_t
```

ECCRAM1STS 1-bit error flag (ECC1ERR).

Set to 1 by hardware when a correctable 1-bit error is detected. Cleared by writing 0 to bit 0. While this flag is set, ECCRAM1ECAD holds the failing address.

00210 k_rx_eccram2sts_clear = 0x00,
00211 } rx_eccram2sts_bits_t;

```

#### 8.19.3.4 rx'eccram'mstpcrc'bits't

```
enum rx_eccram_mstpcrc_bits_t : uint32_t
```

MSTPCRC.MSTPC6 bit position for ECCRAM module-stop control.

Setting MSTPC6 = 1 stops the clock supply to the ECCRAM control logic and the region becomes inaccessible. It must be cleared (bit = 0) before any ECCRAM access – including the zero-initialization pass. The write requires the main system PRCR to be in the "PRC1 unlocked" state (see k\_rx\_prcr←\_unlock\_prc1 in rx\_register\_protection.h).

### 8.19.3.7 rx'eccram'region'addr't

enum `rx_eccram_region_addr_t` : `uintptr_t`

ECCRAM data region start, end, and size.

Physical address range of the ECC-protected RAM region. These are the addresses that application code reads and writes – the control registers live at a separate base (see `rx_eccram_reg_addr_t`).

00087 } rx_eccram_region_addr_t;
```

### 8.19.3.8 rx'eccram'region'size't

enum `rx_eccram_region_size_t` : `uint32_t`

ECCRAM region size in bytes.

Total usable bytes in the ECC-protected region. The driver's zero-initialization loop iterates over this many bytes in 32-bit steps so that every ECC syndrome matches the data before error checking is enabled.

```

8.19.3.12 rx`eccramprcr`bits``t`

```
enum rx_eccramprcr_bits_t : uint8_t
```

ECCRAMPRCR protection register values.

Write-enables ECCRAMMODE and ECCRAM1STSEN. Bits [7:1] are the key KW[6:0] = 1111000b; bit [0] is PRCR. Write 0xF1 to unlock (key + PRCR=1), 0xF0 to lock (key + PRCR=0). Writes with any other key pattern are ignored.

## 8.19.4 Function Documentation

## 8.19.4.1 eccram`regs`()

```
volatile rx_eccram_regs_t * eccram_regs (
 void) [inline], [static]
```

Get pointer to the ECCRAM control register block.

Returns a volatile pointer to the ECCRAM control registers at their fixed hardware address. This is the sole, NASA-Rule-8-compliant way to reach the registers – no macros are used for addresses.

## Returns

Volatile pointer to [rx\\_eccram\\_regs\\_t](#)

## Return values

|          |                                                                             |
|----------|-----------------------------------------------------------------------------|
| Non-NULL | Always returns a valid pointer to <a href="#">k_rx_eccram_reg_base_addr</a> |
|----------|-----------------------------------------------------------------------------|

## Precondition

None (hardware register address is always mapped)

## Postcondition

Pointer is valid for the lifetime of program execution

## Note

Thread Safety: Safe. Returns a constant hardware address with no shared state. Concurrent register reads/writes through the pointer are the caller's concern.

## Example:

```
eccram_regs()->eccramprcr = k_rx_eccramprcr_unlock;
eccram_regs()->eccrammode = k_rx_eccrammode_ecc_with_check;
eccram_regs()->eccramprcr = k_rx_eccramprcr_lock;
```

00420 * @brief Get pointer to the ECCRAM control register block
00421 *
00422 * @details
00423 * Returns a volatile pointer to the ECCRAM control registers at their
00424 * fixed hardware address. This is the sole, NASA-Rule-8-compliant way
00425 * to reach the registers -- no macros are used for addresses.
00426 *
00427 * @return Volatile pointer to rx_eccram_regs_t
00428 * @retval Non-NULL Always returns a valid pointer to k_rx_eccram_reg_base_addr
00429 *
00430 * @pre None (hardware register address is always mapped)
00431 * @post Pointer is valid for the lifetime of program execution
00432 *
00433 * @note Thread Safety: Safe. Returns a constant hardware address with no
00434 * shared state. Concurrent register reads/writes through the pointer
00435 * are the caller's concern.
00436 *
00437 * @par Example:
00438 * @code{.c}
00439 * eccram_regs()->eccramprcr = k_rx_eccramprcr_unlock;
00440 * eccram_regs()->eccrammode = k_rx_eccrammode_ecc_with_check;
00441 * eccram_regs()->eccramprcr = k_rx_eccramprcr_lock;
00442 * @endcode
00443 *
00444 * @see k_rx_eccram_reg_base_addr
00445 * @since Version 1.0.0

`k_elsr_range_b_max` = 45U , `k_elsr_range_c_min` = 48U , `k_elsr_range_c_max` = 57U }  
Address computation adjustments for the three ELSRn register ranges.

## Functions

- static volatile `uint8_t` \* `elc_elcr_reg` (void)  
Get pointer to ELCR register (Event Link Control).
- static volatile `uint8_t` \* `elc_elsr_reg` (`uint8_t` n)  
Get pointer to ELSRn register.
- static volatile `uint8_t` \* `elc_elsr0_reg` (void)  
Get pointer to ELSR0 register (MTU0).
- static volatile `uint8_t` \* `elc_elsr15_reg` (void)  
Get pointer to ELSR15 register (S12AD ELCTRG00N).
- static volatile `uint8_t` \* `elc_elsr45_reg` (void)  
Get pointer to ELSR45 register (S12AD1 ELCTRG10N).
- static volatile `uint8_t` \* `elc_elsr48_reg` (void)  
Get pointer to ELSR48 register (GPTW event source A).
- static volatile `uint8_t` \* `elc_elopa_reg` (void)  
Get pointer to ELOPA register (MTU0/MTU3 option).
- static volatile `uint8_t` \* `elc_elopb_reg` (void)

- Get pointer to ELOPB register (MTU4 option).
- static volatile uint8\_t \* [elc\\_pgr1\\_reg](#) (void)
- Get pointer to PGR1 register (Port Group 1).
- static volatile uint8\_t \* [elc\\_pgr2\\_reg](#) (void)
- Get pointer to PGR2 register (Port Group 2).
- static volatile uint8\_t \* [elc\\_pgc1\\_reg](#) (void)
- Get pointer to PGC1 register (Port Group Control 1).
- static volatile uint8\_t \* [elc\\_pgc2\\_reg](#) (void)
- Get pointer to PGC2 register (Port Group Control 2).
- static volatile uint8\_t \* [elc\\_pdbf1\\_reg](#) (void)
- Get pointer to PDBF1 register (Port Data Buffer 1).
- static volatile uint8\_t \* [elc\\_pdbf2\\_reg](#) (void)
- Get pointer to PDBF2 register (Port Data Buffer 2).
- static volatile uint8\_t \* [elc\\_pel\\_reg](#) (uint8\_t n)
- Get pointer to PELn register (Port Event Link).
- static volatile uint8\_t \* [elc\\_elsegr\\_reg](#) (void)
- Get pointer to ELSEGR register (Software Event Generation).

### 8.21.1 Detailed Description

RX72N Event Link Controller (ELC) Register Definitions.

Complete register definitions for the RX72N Event Link Controller. The ELC uses interrupt requests from peripheral modules as event signals to interconnect peripherals without CPU intervention.

#### ELC Overview

- 135 types of event signals can be directly interconnected
- Timer event input control for MTU, CMT, TMR, TPU, CMTW, GPTW
- Port event I/O control for Port B and Port E
- Software event generation capability

#### Register Organization

| Address      | Size | Description                   |
|--------------|------|-------------------------------|
| 0x0008B100   | 8    | ELCR - Event Link Control     |
| 0x0008B101   | 8    | ELSR0 - MTU0 event link       |
| 0x0008B104   | 8    | ELSR3 - MTU3 event link       |
| ...          | ...  | (various ELSRn registers)     |
| 0x0008B11F   | 8    | ELOPA - MTU0/3 option setting |
| 0x0008B120   | 8    | ELOPB - MTU4 option setting   |
| 0x0008B121   | 8    | ELOPC - CMT1 option setting   |
| 0x0008B122   | 8    | ELOPD - TMR0-3 option setting |
| 0x0008B123-4 | 8    | PGR1/2 - Port group registers |
| 0x0008B125-6 | 8    | PGC1/2 - Port group control   |

| Address       | Size | Description                        |
|---------------|------|------------------------------------|
| 0x0008B127-8  | 8    | PDBF1/2 - Port data buffers        |
| 0x0008B129-C  | 8    | PEL0-3 - Port event link           |
| 0x0008B12D    | 8    | ELSEGR - Software event generation |
| 0x0008B13F    | 8    | ELOPF - TPU0-3 option setting      |
| 0x0008B141    | 8    | ELOPH - CMTW0 option setting       |
| 0x0008B146-4F | 8    | ELSR48-57 - GPTW event links       |

#### NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: N/A (no loops)
- Rule 3: No dynamic memory allocation
- Rule 4: Short accessor functions
- Rule 5: Static assertions verify addresses
- Rule 6: Minimal scope
- Rule 7: N/A
- Rule 8: All constants use C23 typed enums
- Rule 9: No function pointers
- Rule 10: Compiles with -Wall -Wextra -Werror

## 8.21.2 Enumeration Type Documentation

### 8.21.2.1 `elc_addresses_t`

enum `elc_addresses_t` : `uintptr_t`

ELC register addresses.

All addresses verified against RX72N Hardware Manual Ch21.

Note

Addresses verified 2026-01-29 against manual section 21.2

Since

Version 1.0.0

00177 k_elcr_elcon = 0x80U,
00178 } elcr_bits_t;

```

### 8.21.2.4 elop\_timer\_op\_t

```
enum elop_timer_op_t : uint8_t
```

Timer operation selection bits for ELOPA/B/C/D/F/H registers.

Each timer can be configured to perform different operations when an event signal is received. These 2-bit fields are used in the ELOPx registers.

For MTU/TPU timers (ELOPA, ELOPF): 0x02 = Input capture (TCNT -> TGRA). For CMT/TMR/CMTW timers (ELOPC, ELOPD, ELOPH): 0x02 = Event counter.

```

### 8.21.2.11 elsr\_range\_adj\_t

```
enum elsr_range_adj_t : uint8_t
```

Address computation adjustments for the three ELSRn register ranges.

ELSRn registers are NOT contiguous – option and port registers occupy the gaps. There are three separate address ranges:

Range A n=0..28 : address = base + k\_elsr\_range\_a\_adj + n (0x0008B101..0x0008B11D) Range B n=33..45 : address = base + k\_elsr\_range\_b\_adj + n (0x0008B131..0x0008B13D) Range C n=48..57 : address = base + k\_elsr\_range\_c\_adj + n (0x0008B146..0x0008B14F)

Derivation: ELSR0 = 0x0008B101 = base + 1 + 0 -> adj\_a = 1 ELSR33 = 0x0008B131 = base + 0x10 + 33 -> adj\_b = 0x10 ELSR48 = 0x0008B146 = base + 0x16 + 48 -> adj\_c = 0x16

## 8.21.3 Function Documentation

### 8.21.3.1 elc\_elcr\_reg()

```
volatile uint8_t * elc_elcr_reg (
 void) [inline], [static]
```

Get pointer to ELCR register (Event Link Control).

## Returns

Volatile pointer to ELCR register (8-bit)

## Since

Version 1.0.0

Definition at line 568 of file [rx72n\\_elc\\_regs.h](#).

```
00569 {
00570 return (volatile uint8_t*)k_elc_elcr_addr;
00571 }
```

References [k\\_elc\\_elcr\\_addr](#).

## 8.21.3.2 elc\_elopa\_reg()

```
volatile uint8_t * elc_elopa_reg (
 void) [inline], [static]
```

Get pointer to ELOPA register (MTU0/MTU3 option).

## Returns

Volatile pointer to ELOPA register (8-bit)

## Since

Version 1.0.0

Definition at line 642 of file [rx72n\\_elc\\_regs.h](#).

```
00643 {
00644 return (volatile uint8_t*)k_elc_elopa_addr;
00645 }
```

References [k\\_elc\\_elopa\\_addr](#).

## 8.21.3.3 elc\_elopb\_reg()

```
volatile uint8_t * elc_elopb_reg (
 void) [inline], [static]
```

Get pointer to ELOPB register (MTU4 option).

## Returns

Volatile pointer to ELOPB register (8-bit)

## Since

Version 1.0.0

Definition at line 652 of file [rx72n\\_elc\\_regs.h](#).

```
00653 {
00654 return (volatile uint8_t*)k_elc_elopb_addr;
00655 }
```

References [k\\_elc\\_elopb\\_addr](#).

#### 8.21.3.4 `elc_elsegr_reg()`

```
volatile uint8_t * elc_elsegr_reg (
 void) [inline], [static]
```

Get pointer to ELSEGR register (Software Event Generation).

Returns

Volatile pointer to ELSEGR register (8-bit)

Since

Version 1.0.0

Definition at line 733 of file [rx72n\\_elc\\_regs.h](#).

```
00734 {
00735 return (volatile uint8_t*)k_elc_elsegr_addr;
00736 }
```

References [k\\_elc\\_elsegr\\_addr](#).

#### 8.21.3.5 `elc_elsr0_reg()`

```
volatile uint8_t * elc_elsr0_reg (
 void) [inline], [static]
```

Get pointer to ELSR0 register (MTU0).

Returns

Volatile pointer to ELSR0 register (8-bit)

Since

Version 1.0.0

Definition at line 602 of file [rx72n\\_elc\\_regs.h](#).

```
00603 {
00604 return (volatile uint8_t*)k_elc_elsr0_addr;
00605 }
```

References [k\\_elc\\_elsr0\\_addr](#).

### 8.21.3.6 elc\_elsr15\_reg()

```
volatile uint8_t * elc_elsr15_reg (
 void) [inline], [static]
```

Get pointer to ELSR15 register (S12AD ELCTRG00N).

Returns

Volatile pointer to ELSR15 register (8-bit)

Since

Version 1.0.0

Definition at line 612 of file [rx72n\\_elc\\_regs.h](#).

```
00613 {
00614 return (volatile uint8_t*)k_elc_elsr15_addr;
00615 }
```

References [k\\_elc\\_elsr15\\_addr](#).

### 8.21.3.7 elc\_elsr45\_reg()

```
volatile uint8_t * elc_elsr45_reg (
 void) [inline], [static]
```

Get pointer to ELSR45 register (S12AD1 ELCTRG10N).

Returns

Volatile pointer to ELSR45 register (8-bit)

Since

Version 1.0.0

Definition at line 622 of file [rx72n\\_elc\\_regs.h](#).

```
00623 {
00624 return (volatile uint8_t*)k_elc_elsr45_addr;
00625 }
```

References [k\\_elc\\_elsr45\\_addr](#).

### 8.21.3.8 `elc_elsr48_reg()`

```
volatile uint8_t * elc_elsr48_reg (
 void) [inline], [static]
```

Get pointer to ELSR48 register (GPTW event source A).

Returns

Volatile pointer to ELSR48 register (8-bit)

Since

Version 1.0.0

Definition at line 632 of file [rx72n\\_elc\\_regs.h](#).

```
00633 {
00634 return (volatile uint8_t*)k_elc_elsr48_addr;
00635 }
```

References [k\\_elc\\_elsr48\\_addr](#).

### 8.21.3.9 `elc_elsr_reg()`

```
volatile uint8_t * elc_elsr_reg (
 uint8_t n) [inline], [static]
```

Get pointer to ELSRn register.

Parameters

|   |                                                                         |
|---|-------------------------------------------------------------------------|
| n | Register index (0, 3, 4, 7, 10-13, 15, 16, 18-28, 33, 35-38, 45, 48-57) |
|---|-------------------------------------------------------------------------|

Returns

Volatile pointer to ELSRn register (8-bit)

Warning

Not all indices in [0..57] are valid – consult Table 21.2 for the valid set. Passing an invalid index returns a pointer to a reserved or wrong address.

Note

ELSRn registers occupy three non-contiguous ranges; see [elsr\\_range\\_adj\\_t](#).

Since

Version 1.0.0

Definition at line 583 of file [rx72n\\_elc\\_regs.h](#).

```
00584 {
00585 if (n <= k_elsr_range_a_max) {
00586 return (volatile uint8_t*)(uintptr_t)(k_elc_base_addr + k_elsr_range_a_adj + n);
00587 }
00588 if ((n >= k_elsr_range_a_max + 1U) && (n <= k_elsr_range_b_max)) {
00589 return (volatile uint8_t*)(uintptr_t)(k_elc_base_addr + k_elsr_range_b_adj + n);
00590 }
00591 if ((n >= k_elsr_range_c_min) && (n <= k_elsr_range_c_max)) {
00592 return (volatile uint8_t*)(uintptr_t)(k_elc_base_addr + k_elsr_range_c_adj + n);
00593 }
00594 return nullptr;
00595 }
```

References [k\\_elc\\_base\\_addr](#), [k\\_elsr\\_range\\_a\\_adj](#), [k\\_elsr\\_range\\_a\\_max](#), [k\\_elsr\\_range\\_b\\_adj](#), [k\\_elsr\\_range\\_b\\_max](#), [k\\_elsr\\_range\\_c\\_adj](#), [k\\_elsr\\_range\\_c\\_max](#), and [k\\_elsr\\_range\\_c\\_min](#).

### 8.21.3.10 elc\_pdbf1\_reg()

```
volatile uint8_t * elc_pdbf1_reg (
 void) [inline], [static]
```

Get pointer to PDBF1 register (Port Data Buffer 1).

Returns

Volatile pointer to PDBF1 register (8-bit)

Since

Version 1.0.0

Definition at line 702 of file [rx72n\\_elc\\_regs.h](#).

```
00703 {
00704 return (volatile uint8_t*)k_elc_pdbf1_addr;
00705 }
```

References [k\\_elc\\_pdbf1\\_addr](#).

### 8.21.3.11 elc\_pdbf2\_reg()

```
volatile uint8_t * elc_pdbf2_reg (
 void) [inline], [static]
```

Get pointer to PDBF2 register (Port Data Buffer 2).

Returns

Volatile pointer to PDBF2 register (8-bit)

Since

Version 1.0.0

Definition at line 712 of file [rx72n\\_elc\\_regs.h](#).

```
00713 {
00714 return (volatile uint8_t*)k_elc_pdbf2_addr;
00715 }
```

References [k\\_elc\\_pdbf2\\_addr](#).

### 8.21.3.12 `elc_pel_reg()`

```
volatile uint8_t * elc_pel_reg (
 uint8_t n) [inline], [static]
```

Get pointer to PELn register (Port Event Link).

Parameters

|   |                      |
|---|----------------------|
| n | Register index (0-3) |
|---|----------------------|

Returns

Volatile pointer to PELn register (8-bit)

Since

Version 1.0.0

Definition at line 723 of file [rx72n\\_elc\\_regs.h](#).

```
00724 {
00725 return (volatile uint8_t*)(uintptr_t)(k_elc_pel0_addr + n);
00726 }
```

References [k\\_elc\\_pel0\\_addr](#).

### 8.21.3.13 `elc_pgc1_reg()`

```
volatile uint8_t * elc_pgc1_reg (
 void) [inline], [static]
```

Get pointer to PGC1 register (Port Group Control 1).

Returns

Volatile pointer to PGC1 register (8-bit)

Since

Version 1.0.0

Definition at line 682 of file [rx72n\\_elc\\_regs.h](#).

```
00683 {
00684 return (volatile uint8_t*)k_elc_pgc1_addr;
00685 }
```

References [k\\_elc\\_pgc1\\_addr](#).

#### 8.21.3.14 elc\_pgc2\_reg()

```
volatile uint8_t * elc_pgc2_reg (
 void) [inline], [static]
```

Get pointer to PGC2 register (Port Group Control 2).

Returns

Volatile pointer to PGC2 register (8-bit)

Since

Version 1.0.0

Definition at line 692 of file [rx72n\\_elc\\_regs.h](#).

```
00693 {
00694 return (volatile uint8_t*)k_elc_pgc2_addr;
00695 }
```

References [k\\_elc\\_pgc2\\_addr](#).

#### 8.21.3.15 elc\_pgr1\_reg()

```
volatile uint8_t * elc_pgr1_reg (
 void) [inline], [static]
```

Get pointer to PGR1 register (Port Group 1).

Returns

Volatile pointer to PGR1 register (8-bit)

Since

Version 1.0.0

Definition at line 662 of file [rx72n\\_elc\\_regs.h](#).

```
00663 {
00664 return (volatile uint8_t*)k_elc_pgr1_addr;
00665 }
```

References [k\\_elc\\_pgr1\\_addr](#).

### 8.21.3.16 `elc_pgr2_reg()`

```
volatile uint8_t * elc_pgr2_reg (
 void) [inline], [static]
```

Get pointer to PGR2 register (Port Group 2).

Returns

Volatile pointer to PGR2 register (8-bit)

Since

Version 1.0.0

Definition at line 672 of file `rx72n_elc_regs.h`.

```
00673 {
00674 return (volatile uint8_t*)k_elc_pgr2_addr;
00675 }
```

References `k_elc_pgr2_addr`.

## 8.22 `rx72n_elc_regs.h`

```

FACI command codes.

- enum `rx_fpckar_bits_t` : `uint16_t` { `k_fpckar_pcka_mask` = 0x00FF , `k_fpckar_key_shift` = 8 , `k_fpckar_key` = 0x1E00 }

Flash Sequencer Clock Notification Register (FPCKAR) bit definitions.

- enum `rx_fbcent_bits_t` : `uint8_t` { `k_fbcent_bcdir` = (1U << 0) }

Blank Check Control Register (FBCCNT) bit definitions.

- enum `rx_fbcstat_bits_t` : `uint8_t` { `k_fbcstat_bcst` = (1U << 0) }

Blank Check Status Register (FBCSTAT) bit definitions.

- enum `rx_uidr_addresses_t` : `uintptr_t` { `k_uidr0_addr` = 0xFE7F7D90 , `k_uidr1_addr` = 0xFE7F7D94 , `k_uidr2_addr` = 0xFE7F7D98 , `k_uidr3_addr` = 0xFE7F7D9C }

Unique ID Register addresses (Ch62 Section 62.4.23).

- enum `rx_flash_memory_addresses_t` : `uintptr_t` { `k_code_flash_start` = 0xFFC00000 , `k_code_flash_end` = 0xFFFFFFFF , `k_data_flash_start` = 0x00100000 , `k_data_flash_end` = 0x00107FFF }

Flash memory region base and end addresses for the RX72N.

- enum `rx_flash_memory_layout_t` : `uint32_t` { `k_code_flash_size` = 0x00400000 , `k_data_flash_size` = 0x00008000 , `k_code_flash_block_8k` = 0x00002000 , `k_code_flash_block_32k` = 0x00008000 , `k_data_flash_block_64` = 0x00000040 , `k_code_flash_program_unit` , `k_data_flash_program_unit` }

Flash memory region sizes, erase block granularities, and program units.

## Functions

- static volatile `uint16_t` \* `romce_reg` (void)  
Get pointer to ROM Cache Enable Register (ROMCE).
- static volatile `uint16_t` \* `romciv_reg` (void)  
Get pointer to ROM Cache Invalidate Register (ROMCIV).
- static volatile `uint8_t` \* `fweprror_reg` (void)  
Get pointer to Flash P/E Protect Register (FWEPROR).
- static volatile `uint8_t` \* `fastat_reg` (void)  
Get pointer to Flash Access Status Register (FASTAT).
- static volatile `uint8_t` \* `faeint_reg` (void)  
Get pointer to Flash Access Error Interrupt Enable (FAEINT).
- static volatile `uint8_t` \* `frdyie_reg` (void)  
Get pointer to Flash Ready Interrupt Enable (FRDYIE).
- static volatile `uint32_t` \* `fstatr_reg` (void)  
Get pointer to Flash Status Register (FSTATR).
- static volatile `uint16_t` \* `fentryr_reg` (void)  
Get pointer to Flash P/E Mode Entry Register (FENTRYR).
- static volatile `uint16_t` \* `fsuinitr_reg` (void)  
Get pointer to Flash Sequencer Setup Init Register (FSUINITR).
- static volatile `uint32_t` \* `fsaddr_reg` (void)  
Get pointer to FACI Start Address Register (FSADDR).
- static volatile `uint32_t` \* `feaddr_reg` (void)  
Get pointer to FACI End Address Register (FEADDR).
- static volatile `uint16_t` \* `fcmdr_reg` (void)  
Get pointer to FACI Command Register (FCMDR).

- static volatile uint8\_t \* [faci\\_cmd\\_area](#) (void)  
Get pointer to FACI Command Issuing Area.
- static volatile uint16\_t \* [fpckar\\_reg](#) (void)  
Get pointer to Flash Sequencer Clock Register (FPCKAR).
- static volatile uint8\_t \* [eepfclk\\_reg](#) (void)  
Get pointer to Data Flash Access Frequency Register (EPPFCLK).
- static volatile uint8\_t \* [fbccnt\\_reg](#) (void)  
Get pointer to Blank Check Control Register (FBCCNT).
- static volatile uint8\_t \* [fbcstat\\_reg](#) (void)  
Get pointer to Blank Check Status Register (FBCSTAT).
- static volatile uint32\_t \* [fpsaddr\\_reg](#) (void)  
Get pointer to Data Flash Programming Start Address (FPSADDR).
- static volatile uint32\_t \* [fawmon\\_reg](#) (void)  
Get pointer to Flash Access Window Monitor (FAWMON).
- static volatile uint16\_t \* [fcpsr\\_reg](#) (void)  
Get pointer to Flash Sequencer Processing Switch (FCPSR).
- static volatile uint16\_t \* [fsuacr\\_reg](#) (void)  
Get pointer to Flash Startup Area Select (FSUACR).
- static volatile const uint32\_t \* [uidr0\\_reg](#) (void)  
Get pointer to Unique ID Register 0 (UIDR0).
- static volatile const uint32\_t \* [uidr1\\_reg](#) (void)  
Get pointer to Unique ID Register 1 (UIDR1).
- static volatile const uint32\_t \* [uidr2\\_reg](#) (void)  
Get pointer to Unique ID Register 2 (UIDR2).
- static volatile const uint32\_t \* [uidr3\\_reg](#) (void)  
Get pointer to Unique ID Register 3 (UIDR3).

### 8.23.1 Detailed Description

#### RX72N Flash Memory Register Definitions.

Register definitions for the Flash Memory module including ROM cache control, flash programming/erase operations (FACI), and access protection. The RX72N has 4MB code flash and 32KB data flash with hardware-accelerated operations.

### Flash Memory Specifications

| Parameter     | Code Flash         | Data Flash          |
|---------------|--------------------|---------------------|
| Capacity      | 4 MB               | 32 KB               |
| Address Range | FFC00000-FFFF FFFF | 0010 0000-0010 7FFF |
| Program Unit  | 128 bytes          | 4 bytes             |
| Erase Unit    | 8/32 KB block      | 64 bytes            |
| Read Latency  | 1-3 cycles         | FCLK based          |

### FACI Commands (via 0x007E0000)

| Command      | Code | Description             |
|--------------|------|-------------------------|
| Program      | 0xE8 | Write data to flash     |
| Block Erase  | 0x20 | Erase a single block    |
| Blank Check  | 0x71 | Verify area is erased   |
| Status Clear | 0x50 | Clear error status      |
| Forced Stop  | 0xB3 | Abort current operation |

| Command    | Code | Description                |
|------------|------|----------------------------|
| PE Suspend | 0xB0 | Suspend program/erase      |
| PE Resume  | 0xD0 | Resume suspended operation |

#### Module Dependencies

- Module stop: MSTPCRB.MSTPB31 (FCU) - already running at boot

#### Manual References

RX72N Group User's Manual: Hardware (R01UH0824EJ0120 Rev.1.20)

- Chapter 62: Flash Memory (FLASH), pages 2992-3065

#### Note

The flash sequencer (FACI) must be in P/E mode before issuing commands

#### Warning

Programming/erasing code flash while executing from it is restricted

#### Attention

Enable FWEPROR before any programming operations

#### NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 3: No dynamic memory allocation
- Rule 8: All constants use C23 typed enums
- Rule 10: Compiles with -Wall -Wextra -Werror

## 8.23.2 Enumeration Type Documentation

### 8.23.2.1 rx\_eepfclk\_addresses\_t

```
enum rx_eepfclk_addresses_t : uintptr_t
```

Data Flash Memory Access Frequency register address.

Since

Version 1.0.0

Enumerator

|                |                                     |
|----------------|-------------------------------------|
| k_eepfclk_addr | Data Flash Access Frequency Setting |
|----------------|-------------------------------------|

Definition at line 287 of file rx72n\_flash\_regs.h.

```
00287 : uintptr_t {
00288 k_eepfclk_addr = 0x007FC040, /**< Data Flash Access Frequency Setting */
00289 } rx_eepfclk_addresses_t;
```

### 8.23.2.2 rx\_faci\_addresses\_t

```
enum rx_faci_addresses_t : uintptr_t
```

FACI (Flash Application Command Interface) register addresses.

FACI registers control flash programming and erase operations. All registers are in the 0x007FE0xx range.

Memory Map

| Address    | Register | Size | Description                          |
|------------|----------|------|--------------------------------------|
| 0x007FE010 | FASTAT   | 8    | Flash Access Status                  |
| 0x007FE014 | FAEINT   | 8    | Flash Access Error Int Enable        |
| 0x007FE018 | FRDYIE   | 8    | Flash Ready Interrupt Enable         |
| 0x007FE030 | FSADDR   | 32   | FACI Start Address                   |
| 0x007FE034 | FEADDR   | 32   | FACI End Address                     |
| 0x007FE080 | FSTATR   | 32   | Flash Status Register                |

00361 } rx_faeint_bits_t;

```

#### 8.23.2.5 rx`fastat`bits`t

```
enum rx_fastat_bits_t : uint8_t
```

Flash Access Status Register (FASTAT) bit definitions.

FASTAT @ 0x007FE010 indicates flash access violations.

Bit Layout (8-bit)

| Bit     | Name  | R/W | Description                     |
|---------|-------|-----|---------------------------------|
| 7       | CFAE  | R/W | Code Flash Access Violation     |
| 6↔<br>5 | -     | R   | Reserved                        |
| 4       | CMDLK | R   | Command Lock (sequencer locked) |
| 3       | DFAE  | R/W | Data Flash Access Violation     |
| 2↔<br>0 | -     | R   | Reserved                        |

Note

Write 0 to clear CFAE/DFAE after reading 1

Since

Version 1.0.0

Enumerator

00715 k_fbcnt_bcdir = (1U « 0), /**< Blank Check Direction (0=forward, 1=reverse) */
00716 } rx_fbcnt_bits_t;

```

#### 8.23.2.7 rx\_fbcstat\_bits\_t

```
enum rx_fbcstat_bits_t : uint8_t
```

Blank Check Status Register (FBCSTAT) bit definitions.

Since

Version 1.0.0

Enumerator

|               |                                           |
|---------------|-------------------------------------------|
| k_fbcstat_bcs | Blank Check Status (0=blank, 1=not blank) |
|---------------|-------------------------------------------|

Definition at line 739 of file [rx72n\\_flash\\_regs.h](#).

```
00739 : uint8_t {
00740 k_fbcstat_bcs = (1U << 0), /**< Blank Check Status (0=blank, 1=not blank) */
00741 } rx_fbcstat_bits_t;
```

#### 8.23.2.8 rx`fcmr`bits`

```
enum rx_fcmr_bits_t : uint16_t
```

FACI Command Register (FCMDR) bit definitions.

FCMDR @ 0x007FE0A0 contains the two most recent commands received. Read-only register for debugging.

Since

Version 1.0.0

Enumerator

|                   |                                  |
|-------------------|----------------------------------|
| k_fcmr_pcmr_mask  | Previous command mask (bits 7:0) |
| k_fcmr_pcmr_shift | Previous command shift           |
| k_fcmr_cmdr_mask  | Current command mask (bits 15:8) |
| k_fcmr_cmdr_shift | Current command shift            |

Definition at line 593 of file [rx72n\\_flash\\_regs.h](#).

```
00593 : uint16_t {
00594 k_fcmr_pcmr_mask = 0x00FF, /**< Previous command mask (bits 7:0) */
00595 k_fcmr_pcmr_shift = 0, /**< Previous command shift */
00596 k_fcmr_cmdr_mask = 0xFF00, /**< Current command mask (bits 15:8) */
00597 k_fcmr_cmdr_shift = 8, /**< Current command shift */
00598 } rx_fcmr_bits_t;
```

#### 8.23.2.9 rx`fentryr`bits`

```
enum rx_fentryr_bits_t : uint16_t
```

Flash P/E Mode Entry Register (FENTRYR) bit definitions.

FENTRYR @ 0x007FE084 controls entry into P/E (Program/Erase) mode. Write with KEY=0xAA to modify FENTRYC/FENTRYD bits.

## Entry Values

- 0xAA01: Enter code flash P/E mode
- 0xAA80: Enter data flash P/E mode
- 0xAA00: Exit P/E mode (return to read mode)

## Warning

Writing 0xAA81 causes ILGLERR error

## Since

Version 1.0.0

## Enumerator

|                     |                           |
|---------------------|---------------------------|
| k_fentryr_fentryc   | Code Flash P/E Mode Entry |
| k_fentryr_fentryd   | Data Flash P/E Mode Entry |
| k_fentryr_key_shift | Key code position         |
| k_fentryr_key       | Key code (write only)     |
| k_fentryr_code_pe   | Enter code flash P/E mode |
| k_fentryr_data_pe   | Enter data flash P/E mode |
| k_fentryr_read_mode | Exit P/E mode             |

00504 k_fentryr_key = 0xAA00, /**< Key code (write only) */
00505
00506 k_fentryr_code_pe = 0xAA01, /**< Enter code flash P/E mode */
00507 k_fentryr_data_pe = 0xAA80, /**< Enter data flash P/E mode */
00508 k_fentryr_read_mode = 0xAA00, /**< Exit P/E mode */
00509 } rx_fentryr_bits_t;

```

## 8.23.2.10 rx'flash'memory'addresses't

```
enum rx_flash_memory_addresses_t : uintptr_t
```

Flash memory region base and end addresses for the RX72N.

Defines the inclusive address range of each flash region on the RX72N (4 MB code flash, 32 KB data flash). Addresses are physical bus addresses as documented in the RX72N Hardware Manual, Section 5 (Memory Map).

Code flash occupies the top of the 32-bit address space (0xFFC00000 - 0xFFFFFFFF). Data flash is a separate EEPROM-emulation region beginning at 0x00100000. Neither region overlaps RAM or peripheral space.

Use these constants as bounds for range checks before issuing erase or program commands via the Flash Control Unit (FCU). Never use raw literals for flash address comparisons; always reference these enum values so that any future memory-map revision is caught at a single point.

## Note

All addresses must be naturally aligned to the program unit defined in [rx\\_flash\\_memory\\_layout\\_t](#) (128 bytes for code flash, 4 bytes for data flash). Unaligned addresses are rejected by the FCU hardware.

Code flash erase granularity differs by block index: blocks 0-7 are 8 KB each, blocks 8 and above are 32 KB each (see [rx\\_flash\\_memory\\_layout\\_t](#)).

## Invariant

`k_code_flash_start < k_code_flash_end`

`k_data_flash_start < k_data_flash_end`

Code flash and data flash address ranges do not overlap

## Usage Example:

```
bool is_code_flash(uintptr_t addr) {
 return addr >= (uintptr_t)k_code_flash_start &&
 addr <= (uintptr_t)k_code_flash_end;
}
```

## See also

00930 k_code_flash_start = 0xFFC00000, /**< Code flash start address (bottom of 4 MB region) */
00931 k_code_flash_end = 0xFFFFFFFF, /**< Code flash end address (top of 32-bit space) */
00932 k_data_flash_start = 0x00100000, /**< Data flash start address (EEPROM-emulation region) */
00933 k_data_flash_end = 0x00107FFF, /**< Data flash end address (32 KB above start) */
00934 } rx_flash_memory_addresses_t;
```

### 8.23.2.11 rx\_flash\_memory\_layout\_t

```
enum rx_flash_memory_layout_t : uint32_t
```

Flash memory region sizes, erase block granularities, and program units.

Captures the capacity and write/erase geometry of the RX72N flash subsystem as documented in the RX72N Hardware Manual, Sections 7 and 59.

Code flash (4 MB) has a split-block architecture:

- Blocks 0-7: 8 KB each (small blocks at the top of the address space, typically used for bootloader or parameter storage)
- Blocks 8 and above: 32 KB each (large blocks for application code)

Data flash (32 KB) is organised in uniform 64-byte erase blocks and is intended for EEPROM-emulation of configuration data and run-time state.

Program (write) operations must be issued in multiples of the program unit:

- Code flash: 128-byte aligned writes
- Data flash: 4-byte aligned writes

Use these constants when computing erase/program address ranges, validating buffer sizes, or determining which block type covers a given address before issuing FCU commands.

Note

All values are byte counts or byte sizes, not word or block counts.

The program unit constraints are enforced in hardware; the FCU will set FSTATR.PRGERR if an unaligned or undersized write is attempted.

Invariant

```
k_code_flash_size == (k_code_flash_block_8k * 8) + (k_code_flash_block_32k * 126)
k_data_flash_size == k_data_flash_block_64 * 512
```

Usage Example:

```
bool is_aligned_code_flash_write(uintptr_t addr, uint32_t len) {
 return (addr % k_code_flash_program_unit == 0) &&
 (len % k_code_flash_program_unit == 0);
}
```

00156 } rx_romciv_bits_t;
```

#### 8.23.2.21 rx`uidr`addresses` t

```
enum rx_uidr_addresses_t : uintptr_t
```

Unique ID Register addresses (Ch62 Section 62.4.23).

UIDR0-3 contain a 128-bit unique identifier for each chip. These are read-only registers in the FLASH-CONST area (on-chip ROM).

Memory Map (FLASHCONST area)

| Address    | Register | Description         |
|------------|----------|---------------------|
| 0xFE7F7D90 | UIDR0    | Unique ID bits 31-0 |

| Address    | Register | Description           |
|------------|----------|-----------------------|
| 0xFE7F7D94 | UIDR1    | Unique ID bits 63-32  |
| 0xFE7F7D98 | UIDR2    | Unique ID bits 95-64  |
| 0xFE7F7D9C | UIDR3    | Unique ID bits 127-96 |

#### Access Requirements

- Must read in 32-bit units (as per manual specification)
- SYSCR0.ROME must be 1 (on-chip ROM enabled) - this is the default in single-chip mode, so no special setup needed for normal firmware
- ROMCODE/SPCC security settings do NOT block CPU self-reads (only external programmer access)

#### Note

Values are factory-programmed and unique to each chip

These addresses are in FLASHCONST area (FE7F xxxx), not the typical FACL register space (007F xxxx) - this is expected per manual

#### Since

Version 1.0.0

#### Enumerator

```

## 8.23.3 Function Documentation

### 8.23.3.1 eepfclk\_reg()

```
volatile uint8_t * eepfclk_reg (
 void) [inline], [static]
```

Get pointer to Data Flash Access Frequency Register (EPPFCLK).

Returns

Volatile pointer to EEPFCLK register

Since

Version 1.0.0

Definition at line 698 of file [rx72n\\_flash\\_regs.h](#).

```
00699 {
00700 return (volatile uint8_t*)k_eepfclk_addr;
00701 }
```

References [k\\_eepfclk\\_addr](#).

### 8.23.3.2 faci\_cmd\_area()

```
volatile uint8_t * faci_cmd_area (
 void) [inline], [static]
```

Get pointer to FACI Command Issuing Area.

Commands are issued by writing to this 4-byte area. The write sequence depends on the command type.

Returns

Volatile pointer to FACI command area

Since

Version 1.0.0

Definition at line 647 of file [rx72n\\_flash\\_regs.h](#).

```
00648 {
00649 return (volatile uint8_t*)k_faci_cmd_area;
00650 }
```

References [k\\_faci\\_cmd\\_area](#).

### 8.23.3.3 faeint\_reg()

```
volatile uint8_t * faeint_reg (
 void) [inline], [static]
```

Get pointer to Flash Access Error Interrupt Enable (FAEINT).

Returns

Volatile pointer to FAEINT register

Since

Version 1.0.0

Definition at line 368 of file [rx72n\\_flash\\_regs.h](#).

```
00369 {
00370 return (volatile uint8_t*)k_faeint_addr;
00371 }
```

References [k\\_faeint\\_addr](#).

#### 8.23.3.4 fastat\_reg()

```
volatile uint8_t * fastat_reg (
 void) [inline], [static]
```

Get pointer to Flash Access Status Register (FASTAT).

Returns

Volatile pointer to FASTAT register

Since

Version 1.0.0

Definition at line 331 of file [rx72n\\_flash\\_regs.h](#).

```
00332 {
00333 return (volatile uint8_t*)k_fastat_addr;
00334 }
```

References [k\\_fastat\\_addr](#).

#### 8.23.3.5 fawmon\_reg()

```
volatile uint32_t * fawmon_reg (
 void) [inline], [static]
```

Get pointer to Flash Access Window Monitor (FAWMON).

Returns

Volatile pointer to FAWMON register

Since

Version 1.0.0

Definition at line 773 of file [rx72n\\_flash\\_regs.h](#).

```
00774 {
00775 return (volatile uint32_t*)k_fawmon_addr;
00776 }
```

References [k\\_fawmon\\_addr](#).

### 8.23.3.6 fbcnt\_reg()

```
volatile uint8_t * fbcnt_reg (
 void) [inline], [static]
```

Get pointer to Blank Check Control Register (FBCCNT).

Returns

Volatile pointer to FBCCNT register

Since

Version 1.0.0

Definition at line 723 of file [rx72n\\_flash\\_regs.h](#).

```
00724 {
00725 return (volatile uint8_t*)k_fbcnt_addr;
00726 }
```

References [k\\_fbcnt\\_addr](#).

### 8.23.3.7 fbcstat\_reg()

```
volatile uint8_t * fbcstat_reg (
 void) [inline], [static]
```

Get pointer to Blank Check Status Register (FBCSTAT).

Returns

Volatile pointer to FBCSTAT register

Since

Version 1.0.0

Definition at line 748 of file [rx72n\\_flash\\_regs.h](#).

```
00749 {
00750 return (volatile uint8_t*)k_fbcstat_addr;
00751 }
```

References [k\\_fbcstat\\_addr](#).

### 8.23.3.8 fcmdr`reg()

```
volatile uint16_t * fcmdr_reg (
 void) [inline], [static]
```

Get pointer to FSCI Command Register (FCMDR).

Returns

Volatile pointer to FCMDR register

Since

Version 1.0.0

Definition at line 605 of file [rx72n\\_flash\\_regs.h](#).

```
00606 {
00607 return (volatile uint16_t*)k_fcmdr_addr;
00608 }
```

References [k\\_fcmdr\\_addr](#).

### 8.23.3.9 fcpsr`reg()

```
volatile uint16_t * fcpsr_reg (
 void) [inline], [static]
```

Get pointer to Flash Sequencer Processing Switch (FCPSR).

Returns

Volatile pointer to FCPSR register

Since

Version 1.0.0

Definition at line 783 of file [rx72n\\_flash\\_regs.h](#).

```
00784 {
00785 return (volatile uint16_t*)k_fcpsr_addr;
00786 }
```

References [k\\_fcpsr\\_addr](#).

### 8.23.3.10 feaddr\_reg()

```
volatile uint32_t * feaddr_reg (
 void) [inline], [static]
```

Get pointer to FSCI End Address Register (FEADDR).

Returns

Volatile pointer to FEADDR register

Since

Version 1.0.0

Definition at line 573 of file [rx72n\\_flash\\_regs.h](#).

```
00574 {
00575 return (volatile uint32_t*)k_feaddr_addr;
00576 }
```

References [k\\_feaddr\\_addr](#).

### 8.23.3.11 fentryr\_reg()

```
volatile uint16_t * fentryr_reg (
 void) [inline], [static]
```

Get pointer to Flash P/E Mode Entry Register (FENTRYR).

Returns

Volatile pointer to FENTRYR register

Since

Version 1.0.0

Definition at line 516 of file [rx72n\\_flash\\_regs.h](#).

```
00517 {
00518 return (volatile uint16_t*)k_fentryr_addr;
00519 }
```

References [k\\_fentryr\\_addr](#).

### 8.23.3.12 fpckar\_reg()

```
volatile uint16_t * fpckar_reg (
 void) [inline], [static]
```

Get pointer to Flash Sequencer Clock Register (FPCKAR).

Returns

Volatile pointer to FPCKAR register

Since

Version 1.0.0

Definition at line 683 of file [rx72n\\_flash\\_regs.h](#).

```
00684 {
00685 return (volatile uint16_t*)k_fpckar_addr;
00686 }
```

References [k\\_fpckar\\_addr](#).

### 8.23.3.13 fpsaddr\_reg()

```
volatile uint32_t * fpsaddr_reg (
 void) [inline], [static]
```

Get pointer to Data Flash Programming Start Address (FPSADDR).

Returns

Volatile pointer to FPSADDR register

Since

Version 1.0.0

Definition at line 763 of file [rx72n\\_flash\\_regs.h](#).

```
00764 {
00765 return (volatile uint32_t*)k_fpsaddr_addr;
00766 }
```

References [k\\_fpsaddr\\_addr](#).

#### 8.23.3.14 frdyie\_reg()

```
volatile uint8_t * frdyie_reg (
 void) [inline], [static]
```

Get pointer to Flash Ready Interrupt Enable (FRDYIE).

Returns

Volatile pointer to FRDYIE register

Since

Version 1.0.0

Definition at line 393 of file [rx72n\\_flash\\_regs.h](#).

```
00394 {
00395 return (volatile uint8_t*)k_frdyie_addr;
00396 }
```

References [k\\_frdyie\\_addr](#).

#### 8.23.3.15 fsaddr\_reg()

```
volatile uint32_t * fsaddr_reg (
 void) [inline], [static]
```

Get pointer to FSCI Start Address Register (FSADDR).

Returns

Volatile pointer to FSADDR register

Since

Version 1.0.0

Definition at line 563 of file [rx72n\\_flash\\_regs.h](#).

```
00564 {
00565 return (volatile uint32_t*)k_fsaddr_addr;
00566 }
```

References [k\\_fsaddr\\_addr](#).

### 8.23.3.16 fstatr\_reg()

```
volatile uint32_t * fstatr_reg (
 void) [inline], [static]
```

Get pointer to Flash Status Register (FSTATR).

Returns

Volatile pointer to FSTATR register

Since

Version 1.0.0

Definition at line 473 of file [rx72n\\_flash\\_regs.h](#).

```
00474 {
00475 return (volatile uint32_t*)k_fstatr_addr;
00476 }
```

References [k\\_fstatr\\_addr](#).

### 8.23.3.17 fsuacr\_reg()

```
volatile uint16_t * fsuacr_reg (
 void) [inline], [static]
```

Get pointer to Flash Startup Area Select (FSUACR).

Returns

Volatile pointer to FSUACR register

Since

Version 1.0.0

Definition at line 793 of file [rx72n\\_flash\\_regs.h](#).

```
00794 {
00795 return (volatile uint16_t*)k_fsuacr_addr;
00796 }
```

References [k\\_fsuacr\\_addr](#).

### 8.23.3.18 fsuinitr\_reg()

```
volatile uint16_t * fsuinitr_reg (
 void) [inline], [static]
```

Get pointer to Flash Sequencer Setup Init Register (FSUINITR).

Returns

Volatile pointer to FSUINITR register

Since

Version 1.0.0

Definition at line 548 of file [rx72n\\_flash\\_regs.h](#).

```
00549 {
00550 return (volatile uint16_t*)k_fsuinitr_addr;
00551 }
```

References [k\\_fsuinitr\\_addr](#).

### 8.23.3.19 fwepror\_reg()

```
volatile uint8_t * fwepror_reg (
 void) [inline], [static]
```

Get pointer to Flash P/E Protect Register (FWEPROR).

Returns

Volatile pointer to FWEPROR register

Since

Version 1.0.0

Definition at line 220 of file [rx72n\\_flash\\_regs.h](#).

```
00221 {
00222 return (volatile uint8_t*)k_fwepror_addr;
00223 }
```

References [k\\_fwepror\\_addr](#).

### 8.23.3.20 romce\_reg()

```
volatile uint16_t * romce_reg (
 void) [inline], [static]
```

Get pointer to ROM Cache Enable Register (ROMCE).

Returns

Volatile pointer to ROMCE register

Since

Version 1.0.0

Definition at line 163 of file [rx72n\\_flash\\_regs.h](#).

```
00164 {
00165 return (volatile uint16_t*)k_romce_addr;
00166 }
```

References [k\\_romce\\_addr](#).

### 8.23.3.21 romciv\_reg()

```
volatile uint16_t * romciv_reg (
 void) [inline], [static]
```

Get pointer to ROM Cache Invalidate Register (ROMCIV).

Returns

Volatile pointer to ROMCIV register

Since

Version 1.0.0

Definition at line 173 of file [rx72n\\_flash\\_regs.h](#).

```
00174 {
00175 return (volatile uint16_t*)k_romciv_addr;
00176 }
```

References [k\\_romciv\\_addr](#).

### 8.23.3.22 uidr0\_reg()

```
volatile const uint32_t * uidr0_reg (
 void) [inline], [static]
```

Get pointer to Unique ID Register 0 (UIDR0).

Returns

Volatile pointer to UIDR0 register (read-only)

Note

Access may be restricted depending on security settings

Since

Version 1.0.0

Definition at line 845 of file [rx72n\\_flash\\_regs.h](#).

```
00846 {
00847 return (volatile const uint32_t*)k_uidr0_addr;
00848 }
```

References [k\\_uidr0\\_addr](#).

### 8.23.3.23 uidr1\_reg()

```
volatile const uint32_t * uidr1_reg (
 void) [inline], [static]
```

Get pointer to Unique ID Register 1 (UIDR1).

Returns

Volatile pointer to UIDR1 register (read-only)

Since

Version 1.0.0

Definition at line 855 of file [rx72n\\_flash\\_regs.h](#).

```
00856 {
00857 return (volatile const uint32_t*)k_uidr1_addr;
00858 }
```

References [k\\_uidr1\\_addr](#).

#### 8.23.3.24 uidr2\_reg()

```
volatile const uint32_t * uidr2_reg (
 void) [inline], [static]
```

Get pointer to Unique ID Register 2 (UIDR2).

Returns

Volatile pointer to UIDR2 register (read-only)

Since

Version 1.0.0

Definition at line 865 of file [rx72n\\_flash\\_regs.h](#).

```
00866 {
00867 return (volatile const uint32_t*)k_uidr2_addr;
00868 }
```

References [k\\_uidr2\\_addr](#).

#### 8.23.3.25 uidr3\_reg()

```
volatile const uint32_t * uidr3_reg (
 void) [inline], [static]
```

Get pointer to Unique ID Register 3 (UIDR3).

Returns

Volatile pointer to UIDR3 register (read-only)

Since

Version 1.0.0

Definition at line 875 of file [rx72n\\_flash\\_regs.h](#).

```
00876 {
00877 return (volatile const uint32_t*)k_uidr3_addr;
00878 }
```

References [k\\_uidr3\\_addr](#).

=====
00881 * Flash Memory Address Constants
00882 *
=====
00883 */
00884
00885 /**
00886 * @enum rx_flash_memory_addresses_t
00887 * @brief Flash memory region base and end addresses for the RX72N
00888 *
00889 * @details
00890 * Defines the inclusive address range of each flash region on the RX72N
00891 * (4 MB code flash, 32 KB data flash). Addresses are physical bus addresses
00892 * as documented in the RX72N Hardware Manual, Section 5 (Memory Map).
00893 *
00894 * Code flash occupies the top of the 32-bit address space (0xFFC00000 -
00895 * 0xFFFFFFFF). Data flash is a separate EEPROM-emulation region beginning at
00896 * 0x00100000. Neither region overlaps RAM or peripheral space.
00897 *
00898 * Use these constants as bounds for range checks before issuing erase or
00899 * program commands via the Flash Control Unit (FCU). Never use raw literals
00900 * for flash address comparisons; always reference these enum values so that
00901 * any future memory-map revision is caught at a single point.
00902 *
00903 * @note All addresses must be naturally aligned to the program unit defined
00904 * in rx_flash_memory_layout_t (128 bytes for code flash, 4 bytes for
00905 * data flash). Unaligned addresses are rejected by the FCU hardware.
00906 * @note Code flash erase granularity differs by block index: blocks 0-7 are
00907 * 8 KB each, blocks 8 and above are 32 KB each (see rx_flash_memory_layout_t).
00908 *
00909 * @invariant k_code_flash_start < k_code_flash_end
00910 * @invariant k_data_flash_start < k_data_flash_end
00911 * @invariant Code flash and data flash address ranges do not overlap
00912 *
00913 * @par Usage Example:
00914 * @code

```

```

00915 * bool is_code_flash(uintptr_t addr) {
00916 * return addr >= (uintptr_t)k_code_flash_start &&
00917 * addr <= (uintptr_t)k_code_flash_end;
00918 * }
00919 * @endcode
00920 *
00921 * @see rx_flash_memory_layout_t Block sizes and program units for each region
00922 * @see fentryr_reg() FCU entry register that enables erase/program mode
00923 * @see fsaddr_reg() FCU start-address register (set before erase/program)
00924 * @see feaddr_reg() FCU end-address register (set before block erase)
00925 * @see rx_flash.h Higher-level flash API (when implemented)
00926 *
00927 * @since Version 1.0.0
00928 */
00929 typedef enum : uintptr_t {
00930 k_code_flash_start = 0xFFC00000, /**< Code flash start address (bottom of 4 MB region) */
00931 k_code_flash_end = 0xFFFFFFFF, /**< Code flash end address (top of 32-bit space) */
00932 k_data_flash_start = 0x00100000, /**< Data flash start address (EEPROM-emulation region) */
00933 k_data_flash_end = 0x00107FFF, /**< Data flash end address (32 KB above start) */
00934 } rx_flash_memory_addresses_t;
00935
00936 /**
00937 * @enum rx_flash_memory_layout_t
00938 * @brief Flash memory region sizes, erase block granularities, and program units
00939 *
00940 * @details
00941 * Captures the capacity and write/erase geometry of the RX72N flash subsystem
00942 * as documented in the RX72N Hardware Manual, Sections 7 and 59.
00943 *
00944 * Code flash (4 MB) has a split-block architecture:
00945 * - Blocks 0-7: 8 KB each (small blocks at the top of the address space,
00946 * typically used for bootloader or parameter storage)
00947 * - Blocks 8 and above: 32 KB each (large blocks for application code)
00948 *
00949 * Data flash (32 KB) is organised in uniform 64-byte erase blocks and is
00950 * intended for EEPROM-emulation of configuration data and run-time state.
00951 *
00952 * Program (write) operations must be issued in multiples of the program unit:
00953 * - Code flash: 128-byte aligned writes
00954 * - Data flash: 4-byte aligned writes
00955 *
00956 * Use these constants when computing erase/program address ranges, validating
00957 * buffer sizes, or determining which block type covers a given address before
00958 * issuing FCU commands.
00959 *
00960 * @note All values are byte counts or byte sizes, not word or block counts.
00961 * @note The program unit constraints are enforced in hardware; the FCU will
00962 * set FSTATR.PRGERR if an unaligned or undersized write is attempted.
00963 *
00964 * @invariant k_code_flash_size == (k_code_flash_block_8k * 8) + (k_code_flash_block_32k * 126)
00965 * @invariant k_data_flash_size == k_data_flash_block_64 * 512
00966 *
00967 * @par Usage Example:
00968 * @code
00969 bool is_aligned_code_flash_write(uintptr_t addr, uint32_t len) {
00970 return (addr % k_code_flash_program_unit == 0) &&
00971 (len % k_code_flash_program_unit == 0);
00972 }
00973 * @endcode
00974 *
00975 * @see rx_flash_memory_addresses_t Physical start/end addresses for each region
00976 * @see fstatr_reg() FCU status register (check PRGERR after program)
00977 * @see fsaddr_reg() FCU start-address register (set before erase/program)
00978 * @see feaddr_reg() FCU end-address register (set before block erase)
00979 * @see rx_flash.h Higher-level flash API (when implemented)
00980 *
00981 * @since Version 1.0.0

## Functions

- static volatile `rx_gptw_channel_regs_t` \* `gptw0` (void)  
GPTW register inline accessor functions.
- static volatile `rx_gptw_channel_regs_t` \* `gptw1` (void)
- static volatile `rx_gptw_channel_regs_t` \* `gptw2` (void)
- static volatile `rx_gptw_channel_regs_t` \* `gptw3` (void)
- static volatile `rx_gptw_common_regs_t` \* `gptw_common` (void)  
GPTW common register accessor.

### 8.25.1 Detailed Description

#### RX72N GPTW (General PWM Timer) Register Definitions.

This header provides comprehensive register definitions for the RX72N's General PWM Timer (GPTW). The GPTW is a 32-bit timer optimized for motor PWM generation with dead-time control, complementary outputs, and hardware-synchronized ADC triggering.

#### System Architecture Context:

```

* +-----+
* | STAR Motor PWM Generation (GPTW) |
* +-----+
* |
* | PID Output --> GPTW Compare --> GTIOCA/B --> DRV8263H --> Motor |
* | (0-100%) (32-bit) (PWM pins) (H-bridge) (DC motor) |
* |
* | +-----+ |
* | | GPTW Channel Configuration (per motor) | |
* | |
* | | GTPR (Period) = PCLKA / (Prescaler x PWM_Freq) - 1 | |
* | | GTCCRA (Duty) = GTPR x (duty_percent / 100) | |
* | |
* | | @ PCLKA=120MHz, Prescaler=1, PWM_Freq=20kHz: | |
* | | GTPR = 120MHz / 20kHz - 1 = 5999 | |
* | | 50% duty: GTCCRA = 2999 | |
* | +-----+ |
* |
* +-----+
*

```

## GPTW Key Features:

- 32-bit counter resolution (vs MTU's 16-bit)
- 4 independent channels (GPTW0-GPTW3) for 4 motors
- Each channel has 2 outputs (GTIOCA, GTIOCB) for H-bridge control
- Hardware dead-time insertion for shoot-through prevention
- Synchronized start/stop across multiple channels
- ADC trigger generation for current sensing synchronization
- Double/triple buffering for glitch-free duty updates

## Channel to Motor Mapping (STAR Project):

| Channel | Motor | GTIOCA Pin | GTIOCB Pin | DRV8263H |
|---------|-------|------------|------------|----------|
| GPTW0   | M0    | PE5        | PE2        | U1       |
| GPTW1   | M1    | PE4        | PE1        | U2       |
| GPTW2   | M2    | PE3        | PE0        | U3       |
| GPTW3   | M3    | PE7        | PE6        | U4       |

## PWM Timing Specifications:

| Parameter       | Value          | Notes                    |
|-----------------|----------------|--------------------------|
| Clock source    | PCLKA (120MHz) | From clock generator     |
| PWM frequency   | 20 kHz         | Above audible range      |
| Resolution      | 6000 counts    | GTPR = 5999              |
| Duty resolution | 0.0167%        | $1/6000 = 0.0167\%$      |
| Dead time       | 500 ns         | Shoot-through protection |
| Update rate     | 100 Hz         | PID control loop rate    |

## Hardware Requirements:

- CPU: Renesas RX72N @ 240 MHz (ICLK)
- Peripheral clock: PCLKA = 120 MHz (GPTW clock source)
- GPIO: Port E pins configured for GPTW alternate function
- Module stop: MSTPCRA.MSTPA7 = 0 to enable GPTW (RX72N)

## Memory Usage:

- Channel register structure: 216 bytes (0xD8) per channel
- Common register structure: 44 bytes (0x2C)
- No dynamic allocation required

RX72N Group User's Manual: Hardware, Chapter 26 (GPTW)

NASA Power of 10 Compliance:

- Rule 1: [OK] No goto, setjmp, or recursion in accessor functions
- Rule 3: [OK] Zero dynamic allocation - all registers statically mapped
- Rule 8: [OK] All constants as C23 typed enums (addresses, bit fields)
- Rule 10: [OK] Compile with -Wall -Wextra -Werror, zero warnings

SOLID Principles:

- S: Single responsibility - only GPTW register definitions
- O: Open for extension via accessor functions
- I: Interface segregation - channel and common registers separate
- D: Dependency inversion - hardware accessed via typed pointers

Verification Status:

[PASS] VERIFIED (2026-02-03) - Complete verification against Smart Configurator iodefine.h

- All 55 channel registers present and offset-verified
- All 6 common registers present and offset-verified
- 61/61 static assertions (100% coverage)
- Base addresses verified: 0x000C2000-0x000C2300 (channels), 0x000C2B00 (common)
- Structure sizes verified: 216 bytes (channel), 44 bytes (common)
- Reference: iodefine.h lines 10427-11461 (struct st\_gptw)

00048 * | GPTW1 | M1 | PE4 | PE1 | U2 |
00049 * | GPTW2 | M2 | PE3 | PE0 | U3 |
00050 * | GPTW3 | M3 | PE7 | PE6 | U4 |
00051 *
00052 * @par PWM Timing Specifications:
00053 *
00054 * | Parameter | Value | Notes |
00055 * |-----|-----|-----|
00056 * | Clock source | PCLKA (120MHz) | From clock generator |
00057 * | PWM frequency | 20 kHz | Above audible range |
00058 * | Resolution | 6000 counts | GTPR = 5999 |
00059 * | Duty resolution | 0.0167% | 1/6000 = 0.0167% |
00060 * | Dead time | 500 ns | Shoot-through protection |
00061 * | Update rate | 100 Hz | PID control loop rate |
00062 *
00063 * @par Hardware Requirements:
00064 * - CPU: Renesas RX72N @ 240 MHz (ICLK)
00065 * - Peripheral clock: PCLKA = 120 MHz (GPTW clock source)
00066 * - GPIO: Port E pins configured for GPTW alternate function
00067 * - Module stop: MSTPCRA.MSTPA7 = 0 to enable GPTW (RX72N)
00068 *
00069 * @par Memory Usage:
00070 * - Channel register structure: 216 bytes (0xD8) per channel
00071 * - Common register structure: 44 bytes (0x2C)
00072 * - No dynamic allocation required
00073 *
00074 * @see docs/sections/05_motor_control.tex Motor control system design
00075 * @see lib/rx_motor/inc/rx_motor.h Motor control API
00076 * @see lib/rx_drv8263/inc/rx_drv8263.h H-bridge driver interface
00077 * @see RX72N Group User's Manual: Hardware, Chapter 26 (GPTW)
00078 *
00079 * @par NASA Power of 10 Compliance:
00080 * - Rule 1: [OK] No goto, setjmp, or recursion in accessor functions
00081 * - Rule 3: [OK] Zero dynamic allocation - all registers statically mapped
00082 * - Rule 8: [OK] All constants as C23 typed enums (addresses, bit fields)
00083 * - Rule 10: [OK] Compile with -Wall -Wextra -Werror, zero warnings
00084 *
00085 * @par SOLID Principles:
00086 * - S: Single responsibility - only GPTW register definitions
00087 * - O: Open for extension via accessor functions
00088 * - I: Interface segregation - channel and common registers separate
00089 * - D: Dependency inversion - hardware accessed via typed pointers
00090 *
00091 * @par Module Dependencies:
00092 * @dot
00093 * digraph gptw_deps {

- enum `icu_array_sizes_t` : `uint16_t` {  
`k_icu_ir_count` = 256 , `k_icu_dtcer_count` = 256 , `k_icu_ier_count` = 32 , `k_icu_ier_bits_per_reg` = 8 ,  
`k_icu_ipr_count` = 256 , `k_icu_dmrsr_count` = 8 , `k_icu_irqcr_count` = 16 , `k_icu_irqfte_count` = 2 ,  
`k_icu_irqfte_count` = 2 , `k_icu_slibr_count` = 16 , `k_icu_slibr_count` = 64 , `k_icu_sliar_count` = 48 }  
ICU register array dimensions.
- enum `rx_cmt_interrupt_vector_t` : `uint8_t` { `k_vect_cmt0_cmi0` = 28 , `k_vect_cmt1_cmi1` = 29 }  
CMT (Compare Match Timer) interrupt vector numbers.
- enum `rx_sci_interrupt_vector_t` : `uint8_t` { `k_vect_sci9_rxi9` = 102 }  
SCI (Serial Communications Interface) interrupt vector numbers.
- enum `rx_interrupt_priority_t` : `uint8_t` { `k_ipr_level_disable` = 0 , `k_ipr_level_min` = 1 , `k_ipr_level_max` = 15 }  
Interrupt priority levels for IPR registers.

## Functions

- static volatile `rx_icu_regs_t` \* `icu` (void)  
Get pointer to ICU registers.
- static volatile `uint8_t` \* `icu_slibr` (`uint8_t` vec)  
Get pointer to ICU SLIBR source-select register for a SELECTB vector.

### 8.27.1 Detailed Description

#### RX72N ICU Interrupt Controller Unit Register Definitions.

This header provides comprehensive register definitions for the RX72N's Interrupt Controller Unit (ICU). The ICU manages all 256 interrupt sources with configurable priorities, enabling/disabling, and status monitoring.

#### System Architecture Context:

## ICU Key Features:

- 256 interrupt vectors (16-255 usable, 0-15 reserved)
- 16 priority levels (0=disabled, 1=lowest, 15=highest)
- Per-interrupt enable/disable control via IER registers
- Fast interrupt mode (FIR) for single-cycle response
- DTC (Data Transfer Controller) integration
- 16 external IRQ pins with edge/level detection and filtering
- NMI (Non-Maskable Interrupt) with dedicated registers

## STAR Project Interrupt Usage:

| Vector  | Source          | Priority | Description                          |
|---------|-----------------|----------|--------------------------------------|
| 28      | CMT0_CMI0       | 10       | System tick (1 ms, ThreadX)          |
| 29      | CMT1_CMI1       | 8        | Motor control timer                  |
| 72-75   | IRQ8-IRQ11      | varies   | HC-SR04 echo (4 sensors, both edges) |
| 188-191 | INTB188-INTB191 | 14       | POEG fault protection (4 motors)     |

Note on vectors 188-191 (POEG): these are SLIBR software-configurable

interrupt B vectors. The SLIBXR/SLIBR registers (offsets 0x780-0x7CF) must be programmed to route POEGGAI/BI/CI/DI to INTB188-191 respectively. SCI9 (debug UART) is polled, not interrupt-driven; its fixed vectors are 102 (RXI9) and 103 (TXI9). SCI1 fixed vectors are 60 (RXI1) and 61 (TXI1).

## Hardware Requirements:

- CPU: Renesas RX72N with 256-vector interrupt controller
- ICU base address: 0x00087000 (fixed, non-relocatable)
- Register access: 8-bit for IR/IER/IPR, 16-bit for FIR

## Memory Usage:

- Register structure size: 0xA02 bytes (2562 bytes)
- No dynamic allocation required
- Direct memory-mapped register access

docs/sections/03\_hardware\_pinout.tex External IRQ pin assignments  
 lib/rx\_core/inc/rx\_error\_handler.h Error and fault interrupt handling  
 RX72N Group User's Manual: Hardware, Chapter 15 (Interrupt Controller)

## NASA Power of 10 Compliance:

- Rule 1: [OK] No goto, setjmp, or recursion in accessor functions
- Rule 3: [OK] Zero dynamic allocation - all registers statically mapped
- Rule 8: [OK] All constants as C23 typed enums (vectors, priorities)
- Rule 10: [OK] Compile with -Wall -Wextra -Werror, zero warnings

## SOLID Principles:

- S: Single responsibility - only ICU register definitions
- O: Open for extension via accessor functions
- I: Interface segregation - minimal required registers exposed
- D: Dependency inversion - hardware accessed via typed pointers

## Module Dependencies:

## Verification Status:

[PASS] VERIFIED (2026-01-28) - All register offsets verified against RX72N Manual Ch15 section 15.2. Corrections applied:

- NMI register layout corrected (was wrong order)
- DMRSR registers fixed: 8-bit regs at 4-byte aligned addresses (0x400/404/408/...) NOT consecutive bytes as originally implemented

00031 *
00032 * @par ICU Key Features:
00033 * - 256 interrupt vectors (16-255 usable, 0-15 reserved)
00034 * - 16 priority levels (0=disabled, 1=lowest, 15=highest)
00035 * - Per-interrupt enable/disable control via IER registers
00036 * - Fast interrupt mode (FIR) for single-cycle response
00037 * - DTC (Data Transfer Controller) integration
00038 * - 16 external IRQ pins with edge/level detection and filtering
00039 * - NMI (Non-Maskable Interrupt) with dedicated registers
00040 *
00041 * @par STAR Project Interrupt Usage:
00042 *
00043 * | Vector | Source | Priority | Description |
00044 * |-----|-----|-----|-----|
00045 * | 28 | CMT0_CMI0 | 10 | System tick (1 ms, ThreadX) |
00046 * | 29 | CMT1_CMI1 | 8 | Motor control timer |
00047 * | 72-75 | IRQ8-IRQ11 | varies | HC-SR04 echo (4 sensors, both edges) |
00048 * | 188-191 | INTB188-INTB191 | 14 | POEG fault protection (4 motors) |
00049 *
00050 * @par Note on vectors 188-191 (POEG): these are SLIBR software-configurable
00051 * interrupt B vectors. The SLIBXR/SLIBR registers (offsets 0x780-0x7CF) must
00052 * be programmed to route POEGGAI/BI/CI/DI to INTB188-191 respectively.
00053 * SCI9 (debug UART) is polled, not interrupt-driven; its fixed vectors are
00054 * 102 (RXI9) and 103 (TXI9). SCI1 fixed vectors are 60 (RXI1) and 61 (TXI1).
00055 *
00056 * @par Hardware Requirements:
00057 * - CPU: Renesas RX72N with 256-vector interrupt controller
00058 * - ICU base address: 0x00087000 (fixed, non-relocatable)
00059 * - Register access: 8-bit for IR/IER/IPR, 16-bit for FIR
00060 *
00061 * @par Memory Usage:
00062 * - Register structure size: 0xA02 bytes (2562 bytes)
00063 * - No dynamic allocation required

```

```

00064 * - Direct memory-mapped register access
00065 *
00066 * @see docs/sections/03_hardware_pinout.tex External IRQ pin assignments
00067 * @see lib/rx_core/inc/rx_error_handler.h Error and fault interrupt handling
00068 * @see RX72N Group User's Manual: Hardware, Chapter 15 (Interrupt Controller)
00069 *
00070 * @par NASA Power of 10 Compliance:
00071 * - Rule 1: [OK] No goto, setjmp, or recursion in accessor functions
00072 * - Rule 3: [OK] Zero dynamic allocation - all registers statically mapped
00073 * - Rule 8: [OK] All constants as C23 typed enums (vectors, priorities)
00074 * - Rule 10: [OK] Compile with -Wall -Wextra -Werror, zero warnings
00075 *
00076 * @par SOLID Principles:
00077 * - S: Single responsibility - only ICU register definitions
00078 * - O: Open for extension via accessor functions
00079 * - I: Interface segregation - minimal required registers exposed
00080 * - D: Dependency inversion - hardware accessed via typed pointers
00081 *
00082 * @par Module Dependencies:
00083 * @dot
00084 * digraph icu_deps {

00125 * @defgroup rx_icu_regs RX72N ICU Register Definitions
00126 * @brief Interrupt Controller Unit hardware register interface
00127 *
00128 * @details
00129 * Provides memory-mapped register access to the RX72N ICU peripheral
00130 * for interrupt configuration, enabling, and priority management.
00131 *
00132 * @par Quick Start Example - Enable CMT0 Interrupt:
00133 * @code{.c}
00134 * volatile rx_icu_regs_t* icu_regs = icu();
00135 *
00136 * // 1. Clear any pending interrupt request
00137 * icu_regs->ir[k_vect_cmt0_cmi0] = 0x00;
00138 *
00139 * // 2. Set priority (1=lowest, 15=highest, 0=disabled)
00140 * icu_regs->ipr[k_vect_cmt0_cmi0] = 10; // Priority 10
00141 *
00142 * // 3. Enable interrupt in IER register
00143 * // IER[3] bit 4 = vector 28 (CMT0_CMI0)
00144 * // IER index = vector / 8, bit = vector % 8
00145 * uint8_t ier_index = k_vect_cmt0_cmi0 / 8; // = 3
00146 * uint8_t ier_bit = k_vect_cmt0_cmi0 % 8; // = 4
00147 * icu_regs->ier[ier_index] |= (1U « ier_bit);
00148 *
00149 * // 4. Enable global interrupts (in PSW register, done separately)
00150 * @endcode

```

00294 * @struct rx_icu_regs_t
00295 * @brief ICU Register Map for Interrupt Controller Unit
00296 *
00297 * @details
00298 * Memory-mapped register structure for the ICU peripheral. This structure
00299 * provides direct hardware access to interrupt control registers including
00300 * request flags, enable control, priorities, and external IRQ configuration.
00301 *
00302 * @par Interrupt Handling Workflow:
00303 * 1. Peripheral generates interrupt request -> IR[vector] = 1
00304 * 2. ICU checks IER[vector/8] bit (vector%8) for enable
00305 * 3. If enabled, ICU checks IPR[vector] for priority (1-15)
00306 * 4. Higher priority interrupts preempt lower priority
00307 * 5. CPU vectors to interrupt handler
00308 * 6. Handler clears IR[vector] = 0 before returning
00309 *
00310 * @par Usage Example - Configure Multiple Interrupts:
00311 * @code{.c}
00312 * volatile rx_icu_regs_t* icu_regs = icu();
00313 *
00314 * // Disable all interrupts during configuration
00315 * // (typically done with PSW.I bit, not shown here)
00316 *
00317 * // Configure CMT0 (vector 28) - System tick at priority 10
00318 * icu_regs->ir[28] = 0; // Clear pending
00319 * icu_regs->ipr[28] = 10; // Priority 10
00320 * icu_regs->ier[3] |= 0x10; // Enable (IER3 bit 4)
00321 *
00322 * // Configure CMT1 (vector 29) - Motor control at priority 12

```

```

00323 * icu_regs->ir[29] = 0; // Clear pending
00324 * icu_regs->ipr[29] = 12; // Priority 12 (higher than tick)
00325 * icu_regs->ier[3] |= 0x20; // Enable (IER3 bit 5)
00326 *
00327 * // Configure USB (vector 102) - Communication at priority 8
00328 * icu_regs->ir[102] = 0; // Clear pending
00329 * icu_regs->ipr[102] = 8; // Priority 8
00330 * icu_regs->ier[12] |= 0x40; // Enable (IER12 bit 6)
00331 *
00332 * // Re-enable global interrupts (PSW.I = 1)
00333 * @endcode
00334 *
00335 * @par Memory Layout (Total: ~2562 bytes):

00447 * @brief Get pointer to ICU registers
00448 *
00449 * @details
00450 * Returns a volatile pointer to the ICU register structure,
00451 * enabling direct hardware register access for interrupt configuration.
00452 *
00453 * @return Volatile pointer to ICU register structure at 0x00087000
00454 *
00455 * @pre No prerequisites - ICU is always accessible
00456 *
00457 * @post Pointer is immediately usable for register access
00458 * @post No hardware state is modified by this function
00459 *
00460 * @note Thread Safety: Function is reentrant (returns constant address)
00461 * @note Performance: Zero overhead - compiles to single load instruction
00462 *
00463 * @warning Interrupt configuration should be done with global interrupts
00464 * disabled to prevent race conditions
00465 *
00466 * @par Example - Enable/Disable Specific Interrupt:
00467 * @code{.c}
00468 * volatile rx_icu_regs_t* icu_regs = icu();
00469 *
00470 * // Calculate IER index and bit for vector 28
00471 * uint8_t vector = 28;
00472 * uint8_t ier_idx = vector / 8; // = 3
00473 * uint8_t ier_bit = vector % 8; // = 4
00474 *
00475 * // Enable interrupt
00476 * icu_regs->ier[ier_idx] |= (1U « ier_bit);
00477 *
00478 * // Disable interrupt
00479 * icu_regs->ier[ier_idx] &= ~(1U « ier_bit);
00480 *
00481 * // Check if interrupt is pending
00482 * if (icu_regs->ir[vector]) {
00483 * // Interrupt is pending
00484 * icu_regs->ir[vector] = 0; // Clear it
00485 * }
00486 * @endcode
00487 *
00488 * @see rx_icu_regs_t Register structure definition
00489 */

`k_iwdt_rpes_25` = (0x02 << `k_iwdt_iwdtcr_rpes_shift`) , `k_iwdt_rpes_0` = (0x03 << `k_iwdt_iwdtcr_rpes_shift`) ,  
`k_iwdt_rpss_25` = (0x00 << `k_iwdt_iwdtcr_rpss_shift`) ,  
`k_iwdt_rpss_50` = (0x01 << `k_iwdt_iwdtcr_rpss_shift`) ,  
`k_iwdt_rpss_75` = (0x02 << `k_iwdt_iwdtcr_rpss_shift`) , `k_iwdt_rpss_100` = (0x03 << `k_iwdt_iwdtcr_rpss_shift`) }

IWDT Control Register (IWDTCR) Bit Field Values.

- enum `iwdt_iwdtsr_bits_t` : `uint16_t` {  
`k_iwdt_sr_cntval_mask` = 0x3FFF , `k_iwdt_sr_undff_shift` = 14 , `k_iwdt_sr_refef_shift` = 15 ,  
`k_iwdt_sr_undff` = (1U << 14) ,  
`k_iwdt_sr_refef` = (1U << 15) }

IWDT Status Register (IWDTSR) Bit Field Values.

- enum `iwdt_iwdtrcr_bits_t` : `uint8_t` { `k_iwdt_rstirqs_pos` = 7 , `k_iwdt_rcr_rstirqs_mask` = (1U << 7) , `k_iwdt_rstirqs_reset` = (1U << 7) , `k_iwdt_rstirqs_nmi` = 0x00 }

IWDT Reset Control Register (IWDTRCR) Bit Field Values.

- enum `iwdt_iwdtcstpr_shifts_t` : `uint8_t` { `k_iwdt_cstpr_slcstp_pos` = 7 }

IWDTCSTPR bit field positions.

- enum `iwdt_iwdtcstpr_bits_t` : `uint8_t` { `k_iwdt_cstpr_slcstp_mask` = (1U << 7) , `k_iwdt_slcstp_stop` = (1U << 7) , `k_iwdt_slcstp_continue` = 0x00 }

IWDT Count Stop Control Register (IWDTCSTPR) Bit Field Values.

## Functions

- static volatile `rx_iwdt_regs_t * iwdt` (void)  
Get pointer to IWDT registers.

### 8.29.1 Detailed Description

RX72N IWDT Independent Watchdog Timer Register Definitions.

Register definitions for the Independent Watchdog Timer (IWDT) module on the RX72N microcontroller. The IWDT provides critical system monitoring with a dedicated clock source independent of the main system clock.

#### System Architecture

## IWDT vs WDT Comparison

| Feature           | IWDT (This Module)        | WDT                   |
|-------------------|---------------------------|-----------------------|
| Clock Source      | Dedicated 120 kHz         | PCLKB (60 MHz)        |
| Clock Independent | Yes (survives clock fail) | No                    |
| Stop in Software  | No (once started)         | Yes                   |
| Sleep Mode Ctrl   | Yes (IWDTCSTPR)           | No                    |
| Best For          | Production safety         | Development/debugging |
| Timeout Range     | 8.5 ms to 17.5 s          | 4 us to 2.2 s         |

## Key Features

- 14-bit down counter with dedicated 120 kHz oscillator
- Clock-independent operation - resets system even if main clock fails
- Configurable timeout period: 1024 to 16384 cycles
- Configurable clock division: 1 to 256
- Optional window protection to detect too-early refresh
- Sleep mode count stop control (IWDTCSTPR)
- Generates reset or NMI on timeout (configurable)
- Cannot be stopped in software once started (safety feature)

## Timeout Calculation

$$T_{timeout} = \frac{TOPS \times CKS}{f_{IWDTCCLK}}$$

Example with IWDTCCLK = 120 kHz, TOPS = 16384, CKS = 128:

$$T_{timeout} = \frac{16384 \times 128}{120,000} = 17.5 \text{ seconds}$$

## Timeout Period Table (IWDTCCLK = 120 kHz)

| TOPS  | CKS/ $\leftrightarrow$<br>1 | CKS/16 | CKS/64 | CKS/128 | CKS/256 |
|-------|-----------------------------|--------|--------|---------|---------|
| 1024  | 8.5 ms                      | 137 ms | 546 ms | 1.09 s  | 2.18 s  |
| 4096  | 34 ms                       | 546 ms | 2.18 s | 4.37 s  | 8.74 s  |
| 8192  | 68 ms                       | 1.09 s | 4.37 s | 8.74 s  | 17.5 s  |
| 16384 | 137 ms                      | 2.18 s | 8.74 s | 17.5 s  | 35 s*   |

\*Note: 35s exceeds practical limits; use shorter timeouts for safety.

## Hardware Requirements

| Parameter        | Value      | Notes                        |
|------------------|------------|------------------------------|
| Clock Source     | IWDTCLK    | 120 kHz dedicated oscillator |
| Base Address     | 0x00088030 | 9-byte register block        |
| Interrupt Vector | IWDT_WUNI  | IWDT underflow (NMI mode)    |
| Register Count   | 5          | IWDTRR, IWDTCR, IWDTSR, etc. |

## Production Safety Recommendation

The IWDT is recommended for production systems because:

1. Cannot be disabled by software (protects against runaway code)
2. Survives main clock failure
3. Configurable sleep mode behavior

## NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion
- Rule 2: [OK] N/A (no loops in register definitions)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] All accessor functions are single-statement
- Rule 5: [OK] N/A (hardware layer)
- Rule 6: [OK] Minimal scope
- Rule 7: [OK] N/A (no return values to check)
- Rule 8: [OK] All constants use C23 typed enums
- Rule 9: [OK] No function pointers
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

## SOLID Principles

- S: Single responsibility - only IWDT register definitions
- O: Open for extension via additional bit field enums
- L: N/A (no inheritance hierarchy)
- I: Minimal interface - only necessary accessor
- D: N/A (hardware register layer)

## Module Dependencies

- <stdint.h> - Fixed-width integer types

## 8.29.2 Data Structure Documentation

### 8.29.2.1 struct rx`iwdt`regs`t

IWDT Register Map Structure.

Independent Watchdog Timer (IWDT) registers for safety-critical system monitoring. Uses dedicated 120 kHz oscillator that operates independently of the main system clock.

Memory Layout Table

| Offset | Size | Field     | Type          | Description            |
|--------|------|-----------|---------------|------------------------|
| 0x00   | 1    | iwdtrr    | uint8↔<br>_t  | Refresh Register       |
| 0x01   | 1    | reserved0 | -             | Reserved               |
| 0x02   | 2    | iwdtcr    | uint16↔<br>_t | Control Register       |
| 0x04   | 2    | iwdtsr    | uint16↔<br>_t | Status Register        |
| 0x06   | 1    | iwdtrcr   | uint8↔<br>_t  | Reset Control Register |

| Offset | Size | Field     | Type         | Description                     |
|--------|------|-----------|--------------|---------------------------------|
| 0x07   | 1    | reserved1 | -            | Reserved                        |
| 0x08   | 1    | iwdtcstpr | uint8↔<br>_t | Count Stop Control Register     |
| Total  | 9    |           |              | (packed, no additional padding) |

### IWDT Characteristics

- Cannot be stopped once started - This is a safety feature
- Clock-independent - Continues operating if main clock fails
- Sleep mode control - Can stop counting during sleep (IWDTCSSTPR)

### Initialization Example

```
// Configure IWDT for 1-second timeout (production configuration)
volatile rx_iwdt_regs_t* iwdt_regs = iwdt();

// 1. Configure control register BEFORE first refresh
// TOPS=16384 cycles, CKS=div128, RPSS=100%, RPES=0% (no window)
iwdt_regs->iwdtcr = k_iwdt_tops_16384 | k_iwdt_cks_div_128 |
 k_iwdt_rpss_100 | k_iwdt_rpes_0;

// 2. Configure to generate reset on timeout (production)
iwdt_regs->iwdtcr = k_iwdt_rstirqs_reset;

// 3. Configure sleep mode behavior
iwdt_regs->iwdtcstpr = k_iwdt_slcstp_continue; // Keep counting in sleep

// 4. Start IWDT by performing first refresh
// WARNING: IWDT cannot be stopped after this!
iwdt_regs->iwdtrr = k_iwdt_refresh_start; // Write 0x00
iwdt_regs->iwdtrr = k_iwdt_refresh_end; // Write 0xFF - IWDT NOW RUNNING
```

### Refresh Example (in main loop)

```
void app_main_loop(void) {
 while (1) {
 // Perform application tasks
 process_commands();
 update_motors();
 check_safety();

 // Refresh IWDT (must complete both writes atomically)
 iwdt()->iwdtrr = k_iwdt_refresh_start; // 0x00
 iwdt()->iwdtrr = k_iwdt_refresh_end; // 0xFF

 // Wait for next cycle
 tx_thread_sleep(100); // 100ms loop
 }
}
```

### Note

Unlike WDT, IWDT has IWDTCSSTPR for sleep mode control

### Invariant

sizeof(rx\_iwdt\_regs\_t) == 9 bytes

All offsets match RX72N Hardware Manual Ch35

## Warning

IWDT cannot be stopped once started - ensure configuration is correct  
Configuration must be complete before first refresh

## Attention

Recommended for production systems due to clock independence

### 8.29.3 Enumeration Type Documentation

#### 8.29.3.1 iwdt`iwdtcr`bits` t

```
enum iwdt_iwdtcr_bits_t : uint16_t
```

IWDT Control Register (IWDTCR) Bit Field Values.

Configuration values for IWDT timeout period, clock division, and window protection. These values can be OR'd together to configure IWDTCR.

Timeout Calculation

$$T_{timeout} = \frac{TOPS \times CKS}{120,000}$$

Timeout Examples (IWDTCCLK = 120 kHz)

| Configuration            | Timeout |
|--------------------------|---------|
| TOPS_1024 + CKS_DIV_1    | 8.5 ms  |
| TOPS_16384 + CKS_DIV_128 | 17.5 s  |
| TOPS_16384 + CKS_DIV_64  | 8.7 s   |
| TOPS_4096 + CKS_DIV_32   | ~1.1 s  |

Production Configuration Example

```
// 1-second timeout, no window protection
iwdt()->iwdtcr = k_iwdt_tops_16384 | k_iwdt_cks_div_128 |
 k_iwdt_rpss_100 | k_iwdt_rpes_0;
```

Enumerator

|                    |                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| k_iwdt_tops_1024   | 1024 cycles timeout (~8.5ms at 120kHz, no division) Counter loads 0x03FF (1023). Shortest timeout period.                              |
| k_iwdt_tops_4096   | 4096 cycles timeout (~34ms at 120kHz, no division) Counter loads 0x0FFF (4095).                                                        |
| k_iwdt_tops_8192   | 8192 cycles timeout (~68ms at 120kHz, no division) Counter loads 0x1FFF (8191).                                                        |
| k_iwdt_tops_16384  | 16384 cycles timeout (~137ms at 120kHz, no division) Counter loads 0x3FFF (16383). Longest timeout period.                             |
| k_iwdt_cks_div_1   | IWDTCCLK divided by 1 (fastest, shortest timeout). CKS[3:0] = 0000. 120 kHz counter clock.                                             |
| k_iwdt_cks_div_16  | IWDTCCLK divided by 16. CKS[3:0] = 0010. 7.5 kHz counter clock.                                                                        |
| k_iwdt_cks_div_32  | IWDTCCLK divided by 32. CKS[3:0] = 0011. 3.75 kHz counter clock.                                                                       |
| k_iwdt_cks_div_64  | IWDTCCLK divided by 64. CKS[3:0] = 0100. 1.875 kHz counter clock.                                                                      |
| k_iwdt_cks_div_128 | IWDTCCLK divided by 128 (recommended for ~1s timeout). CKS[3:0] = 1111. 937.5 Hz counter clock. With TOPS_16384: ~17.5 second timeout. |
| k_iwdt_cks_div_256 | IWDTCCLK divided by 256 (slowest, longest timeout). CKS[3:0] = 0101. 468.75 Hz counter clock.                                          |
| k_iwdt_rpes_75     | Window closes at 75% counter remaining. Refresh prohibited when counter < 75% of initial value.                                        |

### 8.29.3.2 iwdt\_iwdtcr\_shifts\_t

```
enum iwdt_iwdtcr_shifts_t : uint8_t
```

IWDT Control Register (IWDTCR) Bit Field Positions.

Bit positions for IWDTCR register fields. Used to construct field values.

## Register Layout (16-bit)

| Bits    | Field | Description              |
|---------|-------|--------------------------|
| 1:<br>0 | TOPS  | Timeout period selection |
| 3:<br>2 | -     | Reserved                 |
| 7:<br>4 | CKS   | Clock division ratio     |
| 9:<br>8 | RPES  | Window end position      |
| 11:10   | -     | Reserved                 |
| 13:12   | RPSS  | Window start position    |
| 15:14   | -     | Reserved                 |

Since

Version 1.0.0

## Enumerator

|                          |                                  |
|--------------------------|----------------------------------|
| k_iwdt_iwdtcr_cks_shift  | CKS field position (bits 7:4)    |
| k_iwdt_iwdtcr_rpes_shift | RPES field position (bits 9:8)   |
| k_iwdt_iwdtcr_rpss_shift | RPSS field position (bits 13:12) |

Definition at line 402 of file rx72n\_iwdt\_regs.h.

```

00402 : uint8_t {
00403 k_iwdt_iwdtcr_cks_shift = 4, /**< CKS field position (bits 7:4) */
00404 k_iwdt_iwdtcr_rpes_shift = 8, /**< RPES field position (bits 9:8) */
00405 k_iwdt_iwdtcr_rpss_shift = 12, /**< RPSS field position (bits 13:12) */
00406 } iwdt_iwdtcr_shifts_t;

```

## 8.29.3.3 iwdt\_iwdtcr\_bits\_t

```
enum iwdt_iwdtcr_bits_t : uint8_t
```

IWDT Count Stop Control Register (IWDTCSR) Bit Field Values.

Controls whether the IWDT counter continues during sleep modes. This register is unique to IWDT (WDT does not have this capability).

## Register Layout (8-bit)

| Bit     | Field  | R/W | Description                          |
|---------|--------|-----|--------------------------------------|
| 6:<br>0 | -      | -   | Reserved                             |
| 7       | SLCSTP | R/W | 0=Continue counting, 1=Stop in sleep |

## Sleep Mode Behavior

- Continue (k\_iwdt\_slcstp\_continue): IWDT keeps running in sleep. Ensures system wakes up if sleep takes too long. Recommended.
- Stop (k\_iwdt\_slcstp\_stop): IWDT pauses during sleep. Use only if sleep duration is unpredictable and legitimate.

## Configuration Example

```
// Recommended: Keep counting during sleep
iwdt()->iwdtctpr = k_iwdt_slcstp_continue;

// Alternative: Stop counting during sleep
iwdt()->iwdtctpr = k_iwdt_slcstp_stop;
```

```

### 8.29.3.6 iwdt\_iwdtsr\_bits\_t

```
enum iwdt_iwdtsr_bits_t : uint16_t
```

IWDT Status Register (IWDTSR) Bit Field Values.

Contains the current down-counter value and error flags.

Register Layout (16-bit)

| Bits      | Field  | R/W | Description                           |
|-----------|--------|-----|---------------------------------------|
| 13:↔<br>0 | CNTVAL | R   | Current counter value                 |
| 14        | UNDFE  | R/W | Underflow flag (write 0 to clear)     |
| 15        | REFEF  | R/W | Refresh error flag (write 0 to clear) |

Error Checking Example

```

uint16_t status = iwdt()->iwdtsr;
if (status & k_iwdt_sr_undff) {
 rx_log_warn("IWDT", "Reset was caused by IWDT timeout");
}

```

```

### 8.29.3.7 iwdt`refresh`sequence`

enum [iwdt\\_refresh\\_sequence\\_t](#) : uint8\_t

IWDT Refresh Register (IWDTRR) Write Sequence Values.

The IWDT counter is refreshed by writing a specific two-byte sequence:

1. Write 0x00 (`k_iwdt_refresh_start`)
2. Write 0xFF (`k_iwdt_refresh_end`)

The first refresh also starts the IWDT, which cannot be stopped until reset.

## Refresh Example

```
// Refresh IWDT (atomic - disable interrupts if needed)
iwdt()->iwdtrr = k_iwdt_refresh_start; // Step 1: Write 0x00
iwdt()->iwdtrr = k_iwdt_refresh_end; // Step 2: Write 0xFF
```

## Warning

First refresh starts IWDT permanently

Both writes must complete in sequence - partial refresh is invalid

00178 } iwdt_reserved_sizes_t;
```

### 8.29.3.9 rx\_iwdt\_addresses\_t

enum rx\_iwdt\_addresses\_t : uintptr\_t

IWDT base address constant.

Base address for the Independent Watchdog Timer register block at 0x00088030. The IWDT has a 9-byte register space with 5 registers and 2 reserved bytes.

Memory Map

| Address    | Register  | Size | Description                 |
|------------|-----------|------|-----------------------------|
| 0x00088030 | IWDTRR    | 1    | Refresh Register            |
| 0x00088031 | Reserved  | 1    | -                           |
| 0x00088032 | IWDTCR    | 2    | Control Register            |
| 0x00088034 | IWDTSR    | 2    | Status Register             |
| 0x00088036 | IWDTRCR   | 1    | Reset Control Register      |
| 0x00088037 | Reserved  | 1    | -                           |
| 0x00088038 | IWDTCSTPR | 1    | Count Stop Control Register |

00167 } rx_iwdt_addresses_t;
```

## 8.29.4 Function Documentation

### 8.29.4.1 iwdt()

```
volatile rx_iwdt_regs_t * iwdt (
 void) [inline], [static]
```

Get pointer to IWDT registers.

Returns a volatile pointer to the IWDT register structure at address 0x00088030. The IWDT is recommended for production systems due to its clock-independent operation.

Returns

Volatile pointer to IWDT register structure

Return values

|          |                                                 |
|----------|-------------------------------------------------|
| Non-NULL | Always returns valid pointer (hardware address) |
|----------|-------------------------------------------------|

Precondition

None (hardware register always accessible)

Postcondition

Pointer is valid for the lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

This function is always inlined for zero overhead

Example:

```
// Refresh IWDT
iwdt()->iwdtrr = k_iwdt_refresh_start;
iwdt()->iwdtrr = k_iwdt_refresh_end;

// Check counter value
uint16_t counter = iwdt()->iwdtsr & k_iwdt_sr_cntval_mask;
```

00033 *
00034 * @par IWDT vs WDT Comparison
00035 * | Feature | IWDT (This Module) | WDT |
00036 * |-----|-----|-----|
00037 * | Clock Source | Dedicated 120 kHz | PCLKB (60 MHz) |
00038 * | Clock Independent | Yes (survives clock fail) | No |
00039 * | Stop in Software | No (once started) | Yes |
00040 * | Sleep Mode Ctrl | Yes (IWDTCSTPR) | No |
00041 * | Best For | **Production safety** | Development/debugging |
00042 * | Timeout Range | 8.5 ms to 17.5 s | 4 us to 2.2 s |
00043 *
00044 * @par Key Features
00045 * - 14-bit down counter with dedicated 120 kHz oscillator
00046 * - **Clock-independent operation** - resets system even if main clock fails
00047 * - Configurable timeout period: 1024 to 16384 cycles
00048 * - Configurable clock division: 1 to 256
00049 * - Optional window protection to detect too-early refresh
00050 * - Sleep mode count stop control (IWDTCSTPR)
00051 * - Generates reset or NMI on timeout (configurable)
00052 * - **Cannot be stopped in software once started** (safety feature)
00053 *
00054 * @par Timeout Calculation
00055 * @f[
00056 * T_{timeout} = \frac{TOPS \times CKS}{f_{IWDTCCLK}}
00057 * @f]
00058 *
00059 * Example with IWDTCCLK = 120 kHz, TOPS = 16384, CKS = 128:
00060 * @f[
00061 * T_{timeout} = \frac{16384 \times 128}{120,000} = 17.5 \text{ seconds}
00062 * @f]
00063 *
00064 * @par Timeout Period Table (IWDTCCLK = 120 kHz)
00065 * | TOPS | CKS/1 | CKS/16 | CKS/64 | CKS/128 | CKS/256 |
00066 * |-----|-----|-----|-----|-----|-----|
00067 * | 1024 | 8.5 ms | 137 ms | 546 ms | 1.09 s | 2.18 s |
00068 * | 4096 | 34 ms | 546 ms | 2.18 s | 4.37 s | 8.74 s |
00069 * | 8192 | 68 ms | 1.09 s | 4.37 s | 8.74 s | 17.5 s |
00070 * | 16384 | 137 ms | 2.18 s | 8.74 s | 17.5 s | 35 s* |
00071 *
00072 * *Note: 35s exceeds practical limits; use shorter timeouts for safety.
00073 *
00074 * @par Hardware Requirements
00075 * | Parameter | Value | Notes |
00076 * |-----|-----|-----|
00077 * | Clock Source | IWDTCCLK | 120 kHz dedicated oscillator |
00078 * | Base Address | 0x00088030 | 9-byte register block |
00079 * | Interrupt Vector | IWDTC_WUNI | IWDTC underflow (NMI mode) |
00080 * | Register Count | 5 | IWDTCRR, IWDTCR, IWDTCR, etc. |
00081 *
00082 * @par Production Safety Recommendation
00083 * The IWDTC is recommended for production systems because:
00084 * 1. Cannot be disabled by software (protects against runaway code)
00085 * 2. Survives main clock failure
00086 * 3. Configurable sleep mode behavior
00087 *
00088 * @par NASA Power of 10 Compliance
00089 * - Rule 1: [OK] No goto, setjmp, or recursion
00090 * - Rule 2: [OK] N/A (no loops in register definitions)
00091 * - Rule 3: [OK] No dynamic memory allocation
00092 * - Rule 4: [OK] All accessor functions are single-statement
00093 * - Rule 5: [OK] N/A (hardware layer)
00094 * - Rule 6: [OK] Minimal scope
00095 * - Rule 7: [OK] N/A (no return values to check)
00096 * - Rule 8: [OK] All constants use C23 typed enums
00097 * - Rule 9: [OK] No function pointers

00309 * @brief Get pointer to IWDT registers
00310 *
00311 * @details
00312 * Returns a volatile pointer to the IWDT register structure at address
00313 * 0x00088030. The IWDT is recommended for production systems due to its
00314 * clock-independent operation.
00315 *
00316 * @return Volatile pointer to IWDT register structure
00317 * @retval Non-NULL Always returns valid pointer (hardware address)
00318 *
00319 * @pre None (hardware register always accessible)
00320 * @post Pointer is valid for the lifetime of program execution
00321 *
00322 * @note Thread Safety: Safe - returns constant hardware address
00323 * @note This function is always inlined for zero overhead
00324 *
00325 * @par Example:
00326 * @code{.c}
00327 * // Refresh IWDT
00328 * iwdt()->iwdtrr = k_iwdt_refresh_start;
00329 * iwdt()->iwdtrr = k_iwdt_refresh_end;
00330 *
00331 * // Check counter value
00332 * uint16_t counter = iwdt()->iwdtsr & k_iwdt_sr_cntval_mask;
00333 * @endcode
00334 *
00335 * @see k_iwdt_base_addr Base address constant
00336 * @see rx_iwdt_init() Higher-level initialization
00337 * @since Version 1.0.0
00338 */

Functions

- static volatile `uint8_t` * `opccr_reg` (void)
 Get pointer to OPCCR register.
- static volatile `uint8_t` * `rstckcr_reg` (void)
 Get pointer to RSTCKCR register.
- static volatile `rx_dps_regs_t` * `dps_regs` (void)
 Get pointer to Deep Standby registers.
- static volatile `uint8_t` * `dpsbkr` (void)
 Get pointer to Deep Standby Backup RAM.

8.31.1 Detailed Description

RX72N Low Power Consumption Register Definitions.

Low Power Consumption (LPC) register definitions for operating power control, deep software standby mode, and wake-up interrupt configuration on the RX72N microcontroller. This header complements [rx72n_system_regs.h](#) which contains the main standby (SBYCR) and module stop (MSTPCRA-D) registers.

Register Groups

Address Range	Description
0x000800A0 - 0x000800A1	Operating power control (OPCCR/RSTCKCR)
0x0008C280 - 0x0008C28D	Deep standby control & interrupt
0x0008C2A0 - 0x0008C2BF	Deep standby backup RAM (32 bytes)

Low Power Modes

The RX72N supports several low power modes:

- Sleep Mode: CPU stopped, peripherals run (lowest latency wakeup)
- All-Module Clock Stop Mode: CPU and all modules stopped
- Software Standby Mode: Most oscillators stopped, RAM retained
- Deep Software Standby Mode: Lowest power, backup RAM only

Operating Power Control Modes

Mode	ICLK Max	Description
High-speed (000b)	240 MHz	Full performance
Low-speed 1 (110b)	1 MHz	Low power, PLL off
Low-speed 2 (111b)	264 kHz	Lowest power, HOCO off

NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 3: No dynamic memory allocation
- Rule 8: All constants use C23 typed enums
- Rule 10: Compiles with -Wall -Wextra -Werror

Manual References

- Chapter 11: Low Power Consumption
- Table 11.1: Low Power Consumption Functions
- Table 11.2: Mode Transitions

Verification Status

VERIFIED (2026-01-29) - All register addresses verified against RX72N Manual Rev.1.20, Chapter 11.

8.31.2 Data Structure Documentation

8.31.2.1 struct rx_dps_regs_t

Deep Standby Register Block (non-contiguous).

The deep standby registers are NOT all contiguous in memory:

- 0x0008C280: DPSBYCR
- 0x0008C281: Reserved
- 0x0008C282-0x0008C28D: DPSIER, DPSIFR, DPSIEGR registers

This structure covers the contiguous portion from 0x0008C280 onwards.

Invariant

`sizeof(rx_dps_regs_t) == 14 bytes`

Since

Version 1.0.0

Definition at line 537 of file [rx72n_lpc_regs.h](#).

8.31.3 Enumeration Type Documentation

8.31.3.1 rx_dpsbycr_bits_t

enum [rx_dpsbycr_bits_t](#) : uint8_t

DPSBYCR bit definitions.

Controls deep software standby mode entry and power supply configuration.

DEEPCUT[1:0]

- Power Supply Control]

Value	Standby RAM	USB Resume	LVD	Notes
00b	Powered	Enabled	Active	USB wake-up OK
01b	Not powered	Disabled	Active	RAM data lost
11b	Not powered	Disabled	Off	Lowest power

Note

10b is a prohibited setting for DEEPCUT[1:0].

```

8.31.3.17 rx_rstckcr_bits_t

```
enum rx_rstckcr_bits_t : uint8_t
```

RSTCKCR bit definitions.

Controls clock source switching at the time of release from sleep mode. When enabled, the selected clock source is automatically started upon wake-up from sleep mode.

RSTCKSEL[2:0

- Clock Source Select]

Value	Clock Source
001b	HOCO (High-speed on-chip)
010b	Main clock oscillator

Since

Version 1.0.0

Enumerator

k_rstckcr_rstcksel_hoco	HOCO selected for wake-up
k_rstckcr_rstcksel_main	Main oscillator selected for wake-up
k_rstckcr_rstcksel_mask	RSTCKSEL[2:0] bit mask
k_rstckcr_rstcken	1 = Enable clock source switching

Definition at line 182 of file rx72n_lpc_regs.h.

```

00182      : uint8_t {
00183      /* RSTCKSEL[2:0] - Sleep Mode Return Clock Source Select (bits 2:0) */
00184      k_rstckcr_rstcksel_hoco = 0x01U, /**< HOCO selected for wake-up */
00185      k_rstckcr_rstcksel_main = 0x02U, /**< Main oscillator selected for wake-up */

00187
00188      /* RSTCKEN - Sleep Mode Return Clock Source Switching Enable (bit 7) */
00189      k_rstckcr_rstcken = 0x80U, /**< 1 = Enable clock source switching */
00190 } rx_rstckcr_bits_t;

```

8.31.4 Function Documentation

8.31.4.1 dps_regs()

```
volatile rx_dps_regs_t * dps_regs (
    void ) [inline], [static]
```

Get pointer to Deep Standby registers.

Returns

Volatile pointer to Deep Standby register structure

Provides access to DPSBYCR, DPSIERx, DPSIFRx, and DPSIEGRx registers.

Example - Configure IRQ0 as wake-up source:

```

volatile rx_dps_regs_t* dps = dps_regs();

dps->dpsier0 = k_dpsier0_dirq0e;    // Enable IRQ0-DS wake-up
dps->dpsiegr0 = k_dpsiegr0_dirq0eg; // Rising edge trigger
dps->dpsifr0 = 0x00;                // Clear flags before entering

dps->dpsbycr = k_dpsbycr_dpsby;     // Enable deep standby

```

Since

Version 1.0.0

Definition at line 622 of file [rx72n_lpc_regs.h](#).

```
00623 {
00624     return (volatile rx_dps_regs_t*)k_dpsbycr_base_addr;
00625 }
```

References [k_dpsbycr_base_addr](#).

Referenced by [rx_lpc_enter_deep_software_standby\(\)](#), [rx_lpc_enter_software_standby\(\)](#), and [rx_lpc_init\(\)](#).

Here is the caller graph for this function:

8.31.4.2 `dpsbkr()`

```
volatile uint8_t * dpsbkr (
    void ) [inline], [static]
```

Get pointer to Deep Standby Backup RAM.

Returns

Volatile pointer to 32-byte backup RAM array

DPSBKRY (y=0-31) is 32 bytes of RAM retained during deep software standby mode. Use this to preserve critical state across deep sleep.

Warning

Backup RAM is undefined after power-on; initialize before use.

Example - Save/restore state across deep standby:

```
// Before entering deep standby
volatile uint8_t* bkram = dpsbkr();
bkram[0] = magic_byte_1;
bkram[1] = magic_byte_2;
bkram[2] = (uint8_t)(counter » 8);
bkram[3] = (uint8_t)(counter & 0xFF);

// After waking from deep standby
if (bkram[0] == magic_byte_1 && bkram[1] == magic_byte_2) {
    counter = ((uint16_t)bkram[2] « 8) | bkram[3];
}
```

Since

Version 1.0.0

Definition at line 655 of file [rx72n_lpc_regs.h](#).

```
00656 {  
00657     return (volatile uint8_t*)k_dpsbkr_base_addr;  
00658 }
```

References [k_dpsbkr_base_addr](#).

8.31.4.3 opccr_reg()

```
volatile uint8_t * opccr_reg (  
    void ) [inline], [static]
```

Get pointer to OPCCR register.

Returns

Volatile pointer to Operating Power Control Register

OPCCR controls operating power mode for power optimization.

Example - Enter Low-Speed Mode 1:

```
// Switch to LOCO, then enter low-speed mode 1  
*opccr_reg() = k_opccr_opcm_lowspeed1;  
while (*opccr_reg() & k_opccr_opcmsts) { } // Wait for transition
```

Since

Version 1.0.0

Definition at line 576 of file [rx72n_lpc_regs.h](#).

```
00577 {  
00578     return (volatile uint8_t*)k_opccr_addr;  
00579 }
```

References [k_opccr_addr](#).

Referenced by [rx_lpc_set_operating_power\(\)](#).

Here is the caller graph for this function:

8.31.4.4 rstckcr_reg()

```
volatile uint8_t * rstckcr_reg (
    void ) [inline], [static]
```

Get pointer to RSTCKCR register.

Returns

Volatile pointer to Sleep Mode Return Clock Source Register

RSTCKCR controls automatic clock source switching on sleep mode exit.

Example - Auto-switch to HOCO on wake-up:

```
*rstckcr_reg() = k_rstckcr_rstcken | k_rstckcr_rstcksel_hoco;
```

Since

Version 1.0.0

Definition at line 596 of file [rx72n_lpc_regs.h](#).

```
00597 {
00598     return (volatile uint8_t*)k_rstckcr_addr;
00599 }
```

00001 /**
00002  * @file rx72n_lpc_regs.h
00003  * @brief RX72N Low Power Consumption Register Definitions
00004  *
00005  * @details
00006  * Low Power Consumption (LPC) register definitions for operating power control,
00007  * deep software standby mode, and wake-up interrupt configuration on the RX72N
00008  * microcontroller. This header complements rx72n_system_regs.h which contains
00009  * the main standby (SBYCR) and module stop (MSTPCRA-D) registers.
00010  *
00011  * @par Register Groups
00012  * | Address Range | Description |
00013  * |-----|-----|
00014  * | 0x000800A0 - 0x000800A1 | Operating power control (OPCCR/RSTCKCR) |
00015  * | 0x0008C280 - 0x0008C28D | Deep standby control & interrupt |
00016  * | 0x0008C2A0 - 0x0008C2BF | Deep standby backup RAM (32 bytes) |
00017  *
00018  * @par Low Power Modes
00019  * The RX72N supports several low power modes:
00020  * - **Sleep Mode**: CPU stopped, peripherals run (lowest latency wakeup)
00021  * - **All-Module Clock Stop Mode**: CPU and all modules stopped
00022  * - **Software Standby Mode**: Most oscillators stopped, RAM retained
00023  * - **Deep Software Standby Mode**: Lowest power, backup RAM only
00024  *
00025  * @par Operating Power Control Modes
00026  * | Mode | ICLK Max | Description |
00027  * |-----|-----|-----|
00028  * | High-speed (000b) | 240 MHz | Full performance |
00029  * | Low-speed 1 (110b) | 1 MHz | Low power, PLL off |
00030  * | Low-speed 2 (111b) | 264 kHz | Lowest power, HOCO off |
00031  *
00032  * @par NASA Power of 10 Compliance
00033  * - Rule 1: No goto, setjmp, or recursion
```

```

00034 * - Rule 3: No dynamic memory allocation
00035 * - Rule 8: All constants use C23 typed enums
00036 * - Rule 10: Compiles with -Wall -Wextra -Werror

LVD1CR0/LVD2CR0 register bit definitions.

- enum `rx_lvd_interrupts_t` : `uint8_t` { `k_lvd1_irq` = 88 , `k_lvd2_irq` = 89 }

LVD interrupt vector numbers.

Functions

- static volatile `uint8_t` * `lvd1cr1_reg` (void)
Get pointer to LVD1CR1 register.
- static volatile `uint8_t` * `lvd1sr_reg` (void)
Get pointer to LVD1SR register.
- static volatile `uint8_t` * `lvd2cr1_reg` (void)
Get pointer to LVD2CR1 register.
- static volatile `uint8_t` * `lvd2sr_reg` (void)
Get pointer to LVD2SR register.
- static volatile `uint8_t` * `lvcmpr_reg` (void)
Get pointer to LVCMPCR register.
- static volatile `uint8_t` * `lvdlvlr_reg` (void)
Get pointer to LVDLVLR register.
- static volatile `uint8_t` * `lvd1cr0_reg` (void)
Get pointer to LVD1CR0 register.
- static volatile `uint8_t` * `lvd2cr0_reg` (void)
Get pointer to LVD2CR0 register.

8.33.1 Detailed Description

RX72N Voltage Detection Circuit (LVDA) Register Definitions.

Register definitions for the LVDA module which provides brownout protection and voltage monitoring for safety-critical motor control. The LVDA can trigger resets or interrupts when VCC drops below configurable thresholds.

Voltage Monitoring System

STAR Project LVDA Usage

Monitor	Threshold	Action	Use Case
Vdet0	OFS1 conf	Reset	Emergency brownout protection
Vdet1	2.92V	Interrupt	Low voltage warning
Vdet2	2.85V	Reset	Critical brownout shutdown

Voltage Detection Levels

Level	Voltage (typ)	Hysteresis	Notes
Vdet1↔_1	2.99V	~50mV	Early warning
Vdet1↔_2	2.92V	~50mV	Low voltage threshold
Vdet1↔_3	2.85V	~50mV	Critical threshold

Hardware Requirements

Parameter	Value	Notes
LVD1/2 Regs	0x000800E0	4-byte block
LVCMPCR etc	0x0008C297	5-byte block (non-contiguous)
Enable Time	td(E-A)	Wait after enabling LVDnE
Clock	LOCO (240 kHz)	For digital filter

NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: N/A (no loops in register definitions)
- Rule 3: No dynamic memory allocation
- Rule 4: All accessor functions are single-statement
- Rule 5: N/A (hardware layer)
- Rule 6: Minimal scope - inline accessors only
- Rule 7: N/A (no return values to check)
- Rule 8: All constants use C23 typed enums
- Rule 9: No function pointers
- Rule 10: Compiles with -Wall -Wextra -Werror

Module Dependencies

- `<stdint.h>` - Fixed-width integer types

00400     k_lvd2e_mask = 0x40, /**< LVD2E field mask (bit 6) */
00401 } rx_lvcmpr_bits_t;
```

8.33.2.2 rx`lvd`cr0`bits``t`

enum [rx_lvd_cr0_bits_t](#) : uint8_t

LVD1CR0/LVD2CR0 register bit definitions.

Control bits for interrupt/reset enable, digital filter, and mode selection.

Digital Filter Sampling Clock (FSAMP)

Value	Clock	Sample Time
00	LOCO/2 (120 kHz)	~17 us
01	LOCO/4 (60 kHz)	~33 us
10	LOCO/8 (30 kHz)	~67 us
11	LOCO/16 (15 kHz)	~133 us

Since

Version 1.0.0

Enumerator

k_lvd_rie_disable	Disable interrupt/reset
k_lvd_rie_enable	Enable interrupt/reset
k_lvd_dfdis_filter_on	Digital filter enabled
k_lvd_dfdis_filter_off	Digital filter disabled
k_lvd_cmpe_disable	Output disabled
k_lvd_cmpe_enable	Output enabled
k_lvd_fsamp_loco_div2	LOCO/2 (120 kHz)
k_lvd_fsamp_loco_div4	LOCO/4 (60 kHz)
k_lvd_fsamp_loco_div8	LOCO/8 (30 kHz)
k_lvd_fsamp_loco_div16	LOCO/16 (15 kHz)
k_lvd_ri_interrupt	Generate interrupt on Vdet passage
k_lvd_ri_reset	Generate reset when voltage falls below Vdet
k_lvd_rn_vcc_above	Negate after VCC > Vdet detected
k_lvd_rn_after_assert	Negate after stabilization time from assert
k_lvd_rie_mask	RIE field mask (bit 0)
k_lvd_dfdis_mask	DFDIS field mask (bit 1)
k_lvd_cmpe_mask	CMPE field mask (bit 2)
k_lvd_fsamp_mask	FSAMP field mask (bits 5:4)
k_lvd_ri_mask	RI field mask (bit 6)
k_lvd_rn_mask	RN field mask (bit 7)

Definition at line 458 of file [rx72n_lvda_regs.h](#).

00492 } rx_lvd_cr0_bits_t;

```

8.33.2.3 rx_lvd_cr1_bits_t

```
enum rx_lvd_cr1_bits_t : uint8_t
```

LVD1CR1/LVD2CR1 register bit definitions.

Control bits for interrupt generation condition and type selection.

Interrupt Condition Select (IDTSEL)

Value	Condition
00	VCC >= Vdet (rise) detected
01	VCC < Vdet (drop) detected
10	Both drop and rise detected
11	Prohibited

Since

Version 1.0.0

Enumerator

k_lvd_idtsel_rise	Interrupt on VCC >= Vdet (rise)
k_lvd_idtsel_drop	Interrupt on VCC < Vdet (drop)
k_lvd_idtsel_both	Interrupt on both rise and drop
k_lvd_irqsel_nmi	Non-maskable interrupt
k_lvd_irqsel_maskable	Maskable interrupt
k_lvd_idtsel_mask	IDTSEL field mask (bits 1:0)
k_lvd_irqsel_mask	IRQSEL field mask (bit 2)

Definition at line 346 of file rx72n_lvda_regs.h.

```

00346 : uint8_t {
00347 /* Interrupt generation condition select (IDTSEL) */
00348 k_lvd_idtsel_rise = 0x00, /**< Interrupt on VCC >= Vdet (rise) */

```

```

00350 k_lvd_idtsel_both = 0x02, /**< Interrupt on both rise and drop */
00351
00352 /* Interrupt type select (IRQSEL) */
00353 k_lvd_irqsel_nmi = (0 « 2), /**< Non-maskable interrupt */
00354 k_lvd_irqsel_maskable = (1 « 2), /**< Maskable interrupt */
00355
00356 /* Field masks */
00357 k_lvd_idtsel_mask = 0x03, /**< IDTSEL field mask (bits 1:0) */
00358 k_lvd_irqsel_mask = 0x04, /**< IRQSEL field mask (bit 2) */
00359 } rx_lvd_cr1_bits_t;

```

8.33.2.4 rx_lvd_interrupts_t

```
enum rx_lvd_interrupts_t : uint8_t
```

LVD interrupt vector numbers.

ICU interrupt vector numbers for voltage monitoring. These can be configured as NMI or maskable interrupts.

Since

Version 1.0.0

Enumerator

k_lvd1_irq	LVD1 - Voltage monitor 1 interrupt (Table 15.5 p.512)
k_lvd2_irq	LVD2 - Voltage monitor 2 interrupt (Table 15.5 p.512)

Definition at line 504 of file rx72n_lvda_regs.h.

```

00504 : uint8_t {
00505 k_lvd1_irq = 88, /**< LVD1 - Voltage monitor 1 interrupt (Table 15.5 p.512) */
00506 k_lvd2_irq = 89, /**< LVD2 - Voltage monitor 2 interrupt (Table 15.5 p.512) */
00507 } rx_lvd_interrupts_t;

```

8.33.2.5 rx_lvd_sr_bits_t

```
enum rx_lvd_sr_bits_t : uint8_t
```

LVD1SR/LVD2SR register bit definitions.

Status bits for voltage detection and monitoring.

Since

Version 1.0.0

Enumerator

k_lvd_det_clear	Clear detection flag (write)
k_lvd_det_detected	Vdet passage detected (read)
k_lvd_mon_below	VCC < Vdet (read)
k_lvd_mon_above	VCC >= Vdet or monitor disabled (read)

k_lvd_det_mask	DET flag mask (bit 0)
k_lvd_mon_mask	MON flag mask (bit 1)

Definition at line 370 of file [rx72n_lvda_regs.h](#).

```

00370      : uint8_t {
00371  k_lvd_det_clear    = 0x00, /**< Clear detection flag (write) */
00372  k_lvd_det_detected = 0x01, /**< Vdet passage detected (read) */
00373  k_lvd_mon_below    = 0x00, /**< VCC < Vdet (read) */
00374  k_lvd_mon_above    = 0x02, /**< VCC >= Vdet or monitor disabled (read) */

00376  /** Field masks */
00377  k_lvd_det_mask = 0x01, /**< DET flag mask (bit 0) */
00378  k_lvd_mon_mask = 0x02, /**< MON flag mask (bit 1) */
00379 } rx_lvd_sr_bits_t;

```

8.33.2.6 rx`lvda`addresses`t

```
enum rx_lvda_addresses_t : uintptr_t
```

LVDA register addresses.

The LVDA registers are located in two non-contiguous memory regions:

- Control/Status registers at 0x000800E0-0x000800E3
- Configuration registers at 0x0008C297-0x0008C29B

Memory Map

Address	Register	Size	Description
0x000800E0	LVD1CR1	1	Voltage Monitor 1 Control Reg 1
0x000800E1	LVD1SR	1	Voltage Monitor 1 Status
0x000800E2	LVD2CR1	1	Voltage Monitor 2 Control Reg 1
0x000800E3	LVD2SR	1	Voltage Monitor 2 Status
0x0008C297	LVCMPCR	1	Voltage Monitor Circuit Control
0x0008C298	LVDLVLR	1	Voltage Detection Level Select
0x0008C29A	LVD1CR0	1	Voltage Monitor 1 Control Reg 0
0x0008C29B	LVD2CR0	1	Voltage Monitor 2 Control Reg 0

Note

Manual: Ch8.2 - Register Descriptions

Since

Version 1.0.0

Enumerator

k_lvd1cr1_addr	Voltage Monitor 1 Control Register 1
k_lvd1sr_addr	Voltage Monitor 1 Status Register

00157 } rx_lvda_addresses_t;

```

8.33.2.7 rx_lvdlvlr_bits_t

```
enum rx_lvdlvlr_bits_t : uint8_t
```

LVDLVLR register bit definitions.

Voltage detection level selection for monitors 1 and 2.

Voltage Levels (typical values at Ta = 25degC)

Setting	LVD1LVL/LVD2LVL	Voltage
↔ —↔ 1	1001b (0x09)	2.99V
↔ —↔ 2	1010b (0x0A)	2.92V
↔ —↔ 3	1011b (0x0B)	2.85V

Warning

Other values are prohibited

Note

Can only change when both LVD1E and LVD2E are 0

Since

Version 1.0.0

Enumerator

k_lvd1lvl_2v99	Vdet1 = 2.99V (highest)
k_lvd1lvl_2v92	Vdet1 = 2.92V
k_lvd1lvl_2v85	Vdet1 = 2.85V (lowest)

```

8.33.3 Function Documentation

8.33.3.1 lvcmpcr_reg()

```
volatile uint8_t * lvcmpcr_reg (
    void ) [inline], [static]
```

Get pointer to LVCMPCR register.

Voltage Monitoring Circuit Control Register. Enables/disables voltage detection circuits 1 and 2.

Returns

Volatile pointer to LVCMPCR register

Register Bits:

- b5 LVD1E: Voltage detection 1 circuit enable
- b6 LVD2E: Voltage detection 2 circuit enable

See also

Since

Version 1.0.0

Definition at line 256 of file [rx72n_lvda_regs.h](#).

```
00257 {
00258     return (volatile uint8_t*)k_lvcmpr_addr;
00259 }
```

References [k_lvcmpr_addr](#).

8.33.3.2 lvd1cr0_reg()

```
volatile uint8_t * lvd1cr0_reg (
    void ) [inline], [static]
```

Get pointer to LVD1CR0 register.

Voltage Monitoring 1 Circuit Control Register 0. Controls interrupt/reset enable, digital filter, and comparison output enable.

Returns

Volatile pointer to LVD1CR0 register

Register Bits:

- b0 LVD1RIE: Interrupt/reset enable
- b1 LVD1DFDIS: Digital filter disable (0=enabled, 1=disabled)
- b2 LVD1CMPE: Comparison result output enable
- b5:4 LVD1FSAMP[1:0]: Digital filter sampling clock select
- b6 LVD1RI: Mode select (0=interrupt, 1=reset)
- b7 LVD1RN: Reset negate select

8.33.3.3 lvd1cr1_reg()

```
volatile uint8_t * lvd1cr1_reg (
    void )    [inline], [static]
```

Get pointer to LVD1CR1 register.

Voltage Monitoring 1 Circuit Control Register 1. Controls interrupt generation condition and interrupt type selection.

Returns

Volatile pointer to LVD1CR1 register

Register Bits:

- b1:0 LVD1IDTSEL[1:0]: Interrupt generation condition select
- b2 LVD1IRQSEL: Interrupt type (0=NMI, 1=Maskable)

8.33.3.4 lvd1sr_reg()

```
volatile uint8_t * lvd1sr_reg (
    void )    [inline], [static]
```

Get pointer to LVD1SR register.

Voltage Monitoring 1 Status Register. Contains detection flag and voltage monitor flag.

Returns

Volatile pointer to LVD1SR register

Register Bits:

- b0 LVD1DET: Voltage change detection flag (write 0 to clear)
- b1 LVD1MON: Voltage monitor flag (0=VCC<Vdet1, 1=VCC>=Vdet1)

8.33.3.5 lvd2cr0`reg()

```
volatile uint8_t * lvd2cr0_reg (
    void ) [inline], [static]
```

Get pointer to LVD2CR0 register.

Voltage Monitoring 2 Circuit Control Register 0. Controls interrupt/reset enable, digital filter, and comparison output enable.

Returns

Volatile pointer to LVD2CR0 register

See also

`rx_lvd2cr0_bits_t` Bit definitions

8.33.3.8 lvd1vlr_reg()

```
volatile uint8_t * lvd1vlr_reg (  
    void )    [inline], [static]
```

Get pointer to LVD1VLR register.

Voltage Detection Level Select Register. Sets the detection voltage thresholds for both voltage monitors.

Returns

Volatile pointer to LVD1VLR register

Register Bits:

- b3:0 LVD1LVL[3:0]: Voltage detection 1 level (2.85V/2.92V/2.99V)
- b7:4 LVD2LVL[3:0]: Voltage detection 2 level (2.85V/2.92V/2.99V)

Enumerations

- enum `rx_mpc_addresses_t` : `uintptr_t` { `k_mpc_base_addr` = 0x0008C100 }
- MPC base address (verified against RX72N Hardware Manual Ch23).
- enum `mpc_register_offsets_t` : `uint8_t` {
`k_mpc_offset_pwpr` = 0x1F , `k_mpc_offset_pfs` = 0x40 , `k_mpc_offset_port5_pfs` = 0x28
`k_mpc_offset_porta_pfs` = 0x50 ,
`k_mpc_offset_porte_pfs` = 0x70 , `k_mpc_offset_portj_pfs` = 0x90 , `k_mpc_pfs_total_bytes` }
 Byte offsets of key MPC registers from the MPC base address (0x0008C100).
- enum `mpc_reserved_sizes_t` : `uint8_t` {
`k_mpc_reserved1_bytes` = 1 , `k_mpc_reserved2_bytes` = 4 , `k_mpc_reserved3_bytes` = 16 ,
`k_mpc_reserved4_bytes` = 8 ,
`k_mpc_dscr2_count` = 24 , `k_port3_reserved_bytes` = 3 , `k_port5_reserved_bytes` = 1 ,
`k_port6_reserved_bytes` = 1 ,
`k_port7_reserved_bytes` = 1 , `k_portf_reserved1_bytes` = 2 , `k_portf_reserved2_bytes` = 2 ,
`k_portj_reserved1_bytes` = 1 ,
`k_portj_reserved2_bytes` = 2 }
 MPC register reserved field sizes.
- enum `mpc_pwpr_bits_t` : `uint8_t` { `k_mpc_pwpr_pfswe` = (1 << 6) , `k_mpc_pwpr_b0wi` = (1 << 7) }
- MPC Write Protect Register (PWPR) bit definitions.
- enum `pfs_bits_t` : `uint8_t` { `k_pfs_psel_mask` = 0x1F , `k_pfs_isel` = (1 << 6) , `k_pfs_asel` = (1 << 7) }
- Pin Function Select (PFS) register bit definitions.

Functions

- static volatile `rx_mpc_regs_t * mpc` (void)
Get pointer to MPC registers.

8.35.1 Detailed Description

RX72N Multi-Function Pin Controller (MPC) Register Definitions.

Register definitions for the Multi-Function Pin Controller (MPC) peripheral on the RX72N microcontroller. MPC configures which peripheral function is connected to each GPIO pin (pin multiplexing).

MPC System Architecture

```

* | +-----+ |
* +-----+
*
* PFS Write Protection Sequence:
* +-----+ +-----+ +-----+ +-----+ +-----+
* | PWPR | -> | PWPR | -> | Write | -> | PWPR | -> | PWPR |
* | =0x00 | | =0x40 | | PnmPFS | | =0x00 | | =0x80 |
* | (B0WI=0) | | (PFSWE=1) | | | | (PFSWE=0) | | (B0WI=1) |
* +-----+ +-----+ +-----+ +-----+ +-----+
*
* Memory Map (Verified against RX72N Manual Ch23):
* +-----+
* | Address | Register |
* +-----+
* | 0x0008C100 | PFCSE (CS Output Enable) |
* | 0x0008C102 | PFCSS0/1 (CS Output Pin Select) |
* | 0x0008C104 | PFAOE0/1 (Address Output Enable) |
* | 0x0008C106 | PFBCR0-3 (External Bus Control) |
* | 0x0008C10E | PFENET (Ethernet Control) |
* | 0x0008C11F | PWPR (Write Protect Register) |
* | 0x0008C128 | DSCR2[24] (Drive Capacity Control) |
* | 0x0008C140 | P00PFS - PJ5PFS (Pin Function Select) |
* +-----+
*
* STAR Project Pin Assignments (144-pin LFQFP):
* +-----+
* | Pin | Port | PSEL | Function |
* +-----+
* | USB D+/- | (USB) | - | USB CDC Debug |
* | Pin 72 | PB7 | 0x0A | SCI9-TXD (Debug UART TX) |
* | Pin 74 | PB6 | 0x0A | SCI9-RXD (Debug UART RX) |
* | Pin 32 | PA0 | 0x0D | RSPI0-MOSIA (SPI COPI) |
* | Pin 33 | PA1 | 0x0D | RSPI0-MISOA (SPI CIPO) |
* | Pin 35 | PA3 | 0x0D | RSPI0-RSPCKA (SPI CLK) |
* | Pin 34 | PA4 | 0x0D | RSPI0-SSLA0-B (SPI CS) |
* | Pin 97 | PE5 | 0x1E | GTIOC0A (Motor 0 PWM+) |
* | Pin 96 | PE4 | 0x1E | GTIOC0B (Motor 0 PWM-) |
* | Pin 60 | P24 | 0x02 | MTCLKA (Encoder 0 Phase A) |
* | Pin 61 | P25 | 0x02 | MTCLKB (Encoder 0 Phase B) |
* +-----+
*

```

PFS Register Bit Layout

Each pin has a Pin Function Select (PFS) register:

```

* Bit 7 | Bit 6 | Bit 5 | Bits 4-0
* -----
* ASEL | ISEL | Reserved | PSEL[4:0]
* (Analog) | (IRQ) | | (Peripheral Select)
*

```

Common PSEL Values (varies by pin, check RX72N Manual Appendix)

PSEL	Function Examples
0x00	Hi-Z / General Purpose I/O
0x02	MTU3a clock inputs (MTCLKA-D)
0x1E	GPTW outputs (GTIOCnA/B)
0x0A	SCI (TXD, RXD, SCK, CTS)
0x0D	RSPI (COPI, CIPO, RSPCK, SSL)
0x0F	RIIC (SDA, SCL)

Example: Configure PB7 as SCI9 TXD

```
#include "rx72n_mpc_regs.h"

// Unlock PFS write protection
mpc()->pwpr = 0x00; // Clear B0WI bit
mpc()->pwpr = k_mpc_pwpr_pfswe; // Set PFSWE to enable PFS writes

// Configure PB7 for SCI9 TXD (PSEL = 0x0A)
mpc()->pb7pfs = 0x0A;

// Re-lock PFS write protection
mpc()->pwpr = 0x00; // Clear PFSWE
mpc()->pwpr = k_mpc_pwpr_b0wi; // Set B0WI to protect PFSWE

// Don't forget to also enable peripheral mode in PORT PMR register!
```

NASA Power of 10 Compliance

- Rule 3: No dynamic memory - all register access via static inline functions
- Rule 5: Compile-time assertions verify all register layout assumptions
- Rule 8: Uses typed enums (C23) for all constants, no magic numbers
- Rule 10: Clean build with -Wall -Wextra -Werror

SOLID Principles

- Single Responsibility: MPC register definitions only, no driver logic
- Open/Closed: Accessors work with any pin configuration
- Interface Segregation: Minimal API - just register access functions

Manual Reference

RX72N Group User's Manual: Hardware, Chapter 23 (Multi-Function Pin Controller)

Verification Status

[PASS] VERIFIED (2026-01-28) - All register addresses and offsets verified against RX72N Manual Chapter 23 and Appendix pin function tables.

00091 * @par Example: Configure PB7 as SCI9 TXD
00092 * @code
00093 * #include "rx72n_mpc_regs.h"
00094 *
00095 * // Unlock PFS write protection
00096 * mpc()->pwpr = 0x00; // Clear B0WI bit
00097 * mpc()->pwpr = k_mpc_pwpr_pfswe; // Set PFSWE to enable PFS writes
00098 *
00099 * // Configure PB7 for SCI9 TXD (PSEL = 0x0A)
00100 * mpc()->pb7pfs = 0x0A;
00101 *
00102 * // Re-lock PFS write protection
00103 * mpc()->pwpr = 0x00; // Clear PFSWE
00104 * mpc()->pwpr = k_mpc_pwpr_b0wi; // Set B0WI to protect PFSWE
00105 *
00106 * // Don't forget to also enable peripheral mode in PORT PMR register!
00107 * @endcode
00108 *
00109 * @par NASA Power of 10 Compliance
00110 * - Rule 3: No dynamic memory - all register access via static inline functions
00111 * - Rule 5: Compile-time assertions verify all register layout assumptions
00112 * - Rule 8: Uses typed enums (C23) for all constants, no magic numbers
00113 * - Rule 10: Clean build with -Wall -Wextra -Werror
00114 *
00115 * @par SOLID Principles
00116 * - Single Responsibility: MPC register definitions only, no driver logic
00117 * - Open/Closed: Accessors work with any pin configuration
00118 * - Interface Segregation: Minimal API - just register access functions
00119 *
00120 * @par Manual Reference
00121 * RX72N Group User's Manual: Hardware, Chapter 23 (Multi-Function Pin Controller)
00122 *
00123 * @par Verification Status
00124 * [PASS] VERIFIED (2026-01-28) - All register addresses and offsets verified
00125 * against RX72N Manual Chapter 23 and Appendix pin function tables.

00209 /**
00210  * @brief Pin Function Select Register (C bitfield)
00211  * @details
00212  * Each pin has a PFS register controlling peripheral function selection.
00213  *
00214  * This struct uses C bitfields (the `N` syntax) to pack multiple fields
00215  * into a single byte, matching the hardware register layout exactly:
00216  *
00217  * Bit layout in hardware register (1 byte):
00218  * ```
00219  * 7   6   5   4   3   2   1   0
00220  * +-----+
00221  * | ASEL | ISEL | Reserved | PSEL[4:0] |
00222  * +-----+
00223  * ```
00224  *
00225  * The syntax `volatile uint8_t name : bits` defines a bitfield where:
00226  * - `name` is the field name (or omitted for padding/reserved bits)
00227  * - `bits` is the number of bits the field occupies
00228  *
00229  * Example: `psel : 5` means psel occupies 5 bits (bits 0-4)
00230  *
00231  * This is standard C (not C++) and commonly used in embedded systems
00232  * for hardware register definitions where bits are packed together.
00233  */
00234 typedef struct {
00235     volatile uint8_t psel : 5; /**< Peripheral Select (bits 0-4) */
00236     uint8_t : 1; /**< Reserved bit (bit 5) - unnamed bitfield for padding */

Functions

- static volatile `rx_mpu_region_regs_t` * `mpu_region` (`uint8_t` region)
 Get pointer to MPU region register pair.
- static volatile `uint32_t` * `mpu_rspage_reg` (`uint8_t` region)
 Get pointer to RSPAGE register for a region.
- static volatile `uint32_t` * `mpu_repage_reg` (`uint8_t` region)
 Get pointer to REPAGE register for a region.
- static volatile `uint32_t` * `mpu_mpen_reg` (`void`)
 Get pointer to MPEN (Memory Protection Enable) register.
- static volatile `uint32_t` * `mpu_mpbac_reg` (`void`)
 Get pointer to MPBAC (Background Access Control) register.
- static volatile `uint32_t` * `mpu_mpeclr_reg` (`void`)
 Get pointer to MPECLR (Error Status Clearing) register.
- static volatile `uint32_t` * `mpu_mpests_reg` (`void`)
 Get pointer to MPESTS (Error Status) register.
- static volatile `uint32_t` * `mpu_mpdea_reg` (`void`)
 Get pointer to MPDEA (Data Error Address) register.
- static volatile `uint32_t` * `mpu_mpsa_reg` (`void`)
 Get pointer to MPSA (Region Search Address) register.
- static volatile `uint16_t` * `mpu_mpops_reg` (`void`)
 Get pointer to MPOPS (Region Search Operation) register.
- static volatile `uint16_t` * `mpu_mpopi_reg` (`void`)
 Get pointer to MPOPI (Region Invalidation) register.
- static volatile `uint32_t` * `mpu_mhiti_reg` (`void`)
 Get pointer to MHITI (Instruction Hit Region) register.
- static volatile `uint32_t` * `mpu_mhitd_reg` (`void`)
 Get pointer to MHITD (Data Hit Region) register.
- static `uint32_t` `mpu_addr_to_page` (`uint32_t` addr)
 Convert address to page number.
- static `uint32_t` `mpu_page_to_reg` (`uint32_t` page)
 Convert page number to RSPAGE/REPAGE register value.

8.37.1 Detailed Description

RX72N Memory Protection Unit (MPU) Register Definitions.

Complete register definitions for the RX72N Memory Protection Unit. The MPU provides address-based access control for user-mode programs, protecting code and data regions from unauthorized access.

MPU Overview

- Covers entire 4 GB address space (0x00000000-0xFFFFFFFF)
- 8 independent configurable regions (Region 0-7)
- 16-byte page granularity (smallest unit of protection)
- 3 access types: Execute (X), Write (W), Read (R)
- Protection only active in user mode (supervisor mode bypasses)
- Background region provides default access for unprotected areas
- Overlapping regions use OR of permissions (permission wins)

Register Organization

Address Range	Description
0x00086400-0x043F	Region registers (RSPAGE0-7, REPAGE0-7)
0x00086500-0x052F	Control/status registers

Region Registers (8 regions x 8 bytes each = 64 bytes)

Offset	Register	Description
0x00	RSPAGEn	Region n Start Page Number (32-bit)
0x04	REPAGEn	Region n End Page Number (32-bit)

Control/Status Registers

Address	Size	Register	Description
0x00086500	32	MPEN	Memory Protection Enable
0x00086504	32	MPBAC	Background Access Control
0x00086508	32	MPECLR	Error Status Clearing
0x0008650C	32	MPESTS	Error Status
0x00086514	32	MPDEA	Data Error Address
0x00086520	32	MPSA	Region Search Address
0x00086524	16	MPOPS	Region Search Operation
0x00086526	16	MPOPI	Region Invalidation Operation

Address	Size	Register	Description
0x00086528	32	MHITI	Instruction Hit Region
0x0008652C	32	MHITD	Data Hit Region

NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: N/A (no loops)
- Rule 3: No dynamic memory allocation
- Rule 4: Short accessor functions
- Rule 5: Static assertions verify addresses
- Rule 6: Minimal scope
- Rule 7: N/A
- Rule 8: All constants use C23 typed enums
- Rule 9: No function pointers
- Rule 10: Compiles with -Wall -Wextra -Werror

8.37.2 Data Structure Documentation

8.37.2.1 struct rx_mpu_region_regs_t

MPU per-region register pair.

Memory-mapped register layout for one MPU region. Each region has 8 bytes (RSPAGE + REPAGE).

Note

Structure size verified as 8 bytes.

Since

Version 1.0.0

Definition at line 623 of file [rx72n_mpu_regs.h](#).

Collaboration diagram for rx_mpu_region_regs_t:

Data Fields

volatile uint32_t	repag	Region End Page Number Register (REPAGEn). Bits [31:4] = End page number (inclusive) Bit [3] = Execute permission (UAC.X) Bit [2] = Write permission (UAC.W) Bit [1] = Read permission (UAC.R) Bit [0] = Valid bit (V)
volatile uint32_t	rspag	Region Start Page Number Register (RSPAGEn). Bits [31:4] = Start page number (address[31:4]) Bits [3:0] = Reserved (write 0)

8.37.3 Enumeration Type Documentation

8.37.3.1 mhitd`bits` t

```
enum mhitd_bits_t : uint32_t
```

Data Hit Region Register (MHITD) bit definitions.

After a data memory protection error or region search, this register indicates which region was hit and what permissions were set.

Register Layout (32-bit @ 0x0008652C)

Bits	Field	Description
0	-	Reserved (read as 0)
3:↔ 1	UHACD[2:↔ 0]	Hit region access control (RWX)
15:↔ 4	-	Reserved (read as 0)
23:16	HITD[7:↔ 0]	Region hit flags (1=hit in region)
31:24	-	Reserved (read as 0)

Note

HITD[7:0] = 0 means error in background region

Manual ref: Ch17 section 17.2.12

Since

Version 1.0.0

Enumerator

k_mhitd_uhacd_r	Read permission in hit region (bit 1).
k_mhitd_uhacd_w	Write permission in hit region (bit 2).
k_mhitd_uhacd_x	Execute permission in hit region (bit 3).
k_mhitd_uhacd_mask	Access control bits mask (bits 3:1).
k_mhitd_hitd0	Region 0 hit flag (bit 16).
k_mhitd_hitd1	Region 1 hit flag (bit 17).
k_mhitd_hitd2	Region 2 hit flag (bit 18).
k_mhitd_hitd3	Region 3 hit flag (bit 19).
k_mhitd_hitd4	Region 4 hit flag (bit 20).
k_mhitd_hitd5	Region 5 hit flag (bit 21).

k_mhited_hitd6	Region 6 hit flag (bit 22).
k_mhited_hitd7	Region 7 hit flag (bit 23).
k_mhited_hitd_mask	Hit region flags mask (bits 23:16).
k_mhited_hitd_shift	Hit region flags shift amount.

```
enum mhited_bits_t : uint32_t
```

Instruction Hit Region Register (MHITI) bit definitions.

After an instruction memory protection error, this register indicates which region caused the error and what permissions were set.

Register Layout (32-bit @ 0x00086528)

Bits	Field	Description
0	-	Reserved (read as 0)

Bits	Field	Description
3:↵ 1	UHACI[2:↵ 0]	Hit region access control (RWX)
15:↵ 4	-	Reserved (read as 0)
23:16	HITI[7:↵ 0]	Region hit flags (1=hit in region)
31:24	-	Reserved (read as 0)

Note

HITI[7:0] = 0 means error in background region

Manual ref: Ch17 section 17.2.11

Since

Version 1.0.0

Enumerator

k_mhiti_uhaci_r	Read permission in hit region (bit 1).
k_mhiti_uhaci_w	Write permission in hit region (bit 2).
k_mhiti_uhaci_x	Execute permission in hit region (bit 3).
k_mhiti_uhaci_mask	Access control bits mask (bits 3:1).
k_mhiti_hiti0	Region 0 hit flag (bit 16).

00154 } mpu_region_t;

```

8.37.3.12 repage_bits_t

```
enum repage_bits_t : uint32_t
```

Region End Page Number Register (REPAGEn) bit definitions.

Specifies the ending page number and access control for a protection region. The end page is INCLUDED in the protected region.

Register Layout (32-bit @ 0x00086404 + n*8)

Bits	Field	Description
0	V	Valid (0=invalid, 1=valid)
1	UAC.R	Read permission (0=no, 1=yes)
2	UAC.W	Write permission (0=no, 1=yes)
3	UAC.X	Execute permission (0=no, 1=yes)
31:↵ 4	REPN[27:↵ 0]	Region End Page Number

Note

Manual ref: Ch17 section 17.2.2

Since

Version 1.0.0

Enumerator

k_repage_v	Valid bit (bit 0) - Region enabled when set.
------------	--

k_repage_uac_r	Read permission (bit 1) - Allow data read.
k_repage_uac_w	Write permission (bit 2) - Allow data write.
k_repage_uac_x	Execute permission (bit 3) - Allow instruction fetch.
k_repage_uac_mask	Access control bits mask (UAC[2:0] = bits 3:1).
k_repage_uac_shift	Access control shift amount.
k_repage_repn_mask	End page number field mask (bits 31:4).
k_repage_repn_shift	End page number shift amount.
k_repage_uac_ro	Read-only region (R).
k_repage_uac_rw	Read-write region (RW).
k_repage_uac_xo	Execute-only region (X).
k_repage_uac_rx	Read-execute region (RX).
k_repage_uac_rwx	Full access region (RWX).

```

8.37.4 Function Documentation

8.37.4.1 mpu_addr_to_page()

```
uint32_t mpu_addr_to_page (
    uint32_t addr) [inline], [static]
```

Convert address to page number.

Parameters

addr	Memory address
------	----------------

Returns

Page number (address[31:4])

Example:

```
uint32_t page = mpu_addr_to_page(0x00012340);
// page = 0x00001234
```

Since

Version 1.0.0

Definition at line 822 of file [rx72n_mpu_regs.h](#).

```
00823 {
00824     return (addr » k_mpu_page_shift) & k_mpu_page_max;
00825 }
```

References [k_mpu_page_max](#), and [k_mpu_page_shift](#).

8.37.4.2 mpu_mhيتدreg()

```
volatile uint32_t * mpu_mhيتدreg (
    void )    [inline], [static]
```

Get pointer to MHITD (Data Hit Region) register.

Returns

Volatile pointer to MHITD register (32-bit)

Since

Version 1.0.0

Definition at line 798 of file [rx72n_mpu_regs.h](#).

```
00799 {
00800     return (volatile uint32_t*)k_mpu_mhيتد_addr;
00801 }
```

References [k_mpu_mhيتد_addr](#).

8.37.4.3 mpu_mhيتreg()

```
volatile uint32_t * mpu_mhيتreg (
    void )    [inline], [static]
```

Get pointer to MHITI (Instruction Hit Region) register.

Returns

Volatile pointer to MHITI register (32-bit)

Since

Version 1.0.0

Definition at line 788 of file [rx72n_mpu_regs.h](#).

```
00789 {
00790     return (volatile uint32_t*)k_mpu_mhيت_addr;
00791 }
```

References [k_mpu_mhيت_addr](#).

8.37.4.4 mpu`mpbac`reg()

```
volatile uint32_t * mpu__mpbac_reg (  
    void )    [inline], [static]
```

Get pointer to MPBAC (Background Access Control) register.

Returns

Volatile pointer to MPBAC register (32-bit)

Since

Version 1.0.0

Definition at line 718 of file [rx72n_mpu_regs.h](#).

```
00719 {  
00720     return (volatile uint32_t*)k_mpu__mpbac_addr;  
00721 }
```

References [k_mpu__mpbac_addr](#).

8.37.4.5 mpu`mpdea`reg()

```
volatile uint32_t * mpu__mpdea_reg (  
    void )    [inline], [static]
```

Get pointer to MPDEA (Data Error Address) register.

Returns

Volatile pointer to MPDEA register (32-bit)

Since

Version 1.0.0

Definition at line 748 of file [rx72n_mpu_regs.h](#).

```
00749 {  
00750     return (volatile uint32_t*)k_mpu__mpdea_addr;  
00751 }
```

References [k_mpu__mpdea_addr](#).

8.37.4.6 mpu_mpeclr_reg()

```
volatile uint32_t * mpu_mpeclr_reg (  
    void )    [inline], [static]
```

Get pointer to MPECLR (Error Status Clearing) register.

Returns

Volatile pointer to MPECLR register (32-bit)

Since

Version 1.0.0

Definition at line 728 of file [rx72n_mpu_regs.h](#).

```
00729 {  
00730     return (volatile uint32_t*)k_mpu_mpeclr_addr;  
00731 }
```

References [k_mpu_mpeclr_addr](#).

8.37.4.7 mpu_mpen_reg()

```
volatile uint32_t * mpu_mpen_reg (  
    void )    [inline], [static]
```

Get pointer to MPEN (Memory Protection Enable) register.

Returns

Volatile pointer to MPEN register (32-bit)

Since

Version 1.0.0

Definition at line 708 of file [rx72n_mpu_regs.h](#).

```
00709 {  
00710     return (volatile uint32_t*)k_mpu_mpen_addr;  
00711 }
```

References [k_mpu_mpen_addr](#).

8.37.4.8 mpu`mpests`reg()

```
volatile uint32_t * mpu_mpests_reg (  
    void )    [inline], [static]
```

Get pointer to MPESTS (Error Status) register.

Returns

Volatile pointer to MPESTS register (32-bit)

Since

Version 1.0.0

Definition at line 738 of file [rx72n_mpu_regs.h](#).

```
00739 {  
00740     return (volatile uint32_t*)k_mpu_mpests_addr;  
00741 }
```

References [k_mpu_mpests_addr](#).

8.37.4.9 mpu`mpopi`reg()

```
volatile uint16_t * mpu_mpopi_reg (  
    void )    [inline], [static]
```

Get pointer to MPOPI (Region Invalidation) register.

Returns

Volatile pointer to MPOPI register (16-bit)

Since

Version 1.0.0

Definition at line 778 of file [rx72n_mpu_regs.h](#).

```
00779 {  
00780     return (volatile uint16_t*)k_mpu_mpopi_addr;  
00781 }
```

References [k_mpu_mpopi_addr](#).

8.37.4.10 mpu`mpops`reg()

```
volatile uint16_t * mpu__mpops_reg (  
    void )    [inline], [static]
```

Get pointer to MPOPS (Region Search Operation) register.

Returns

Volatile pointer to MPOPS register (16-bit)

Since

Version 1.0.0

Definition at line 768 of file [rx72n_mpu_regs.h](#).

```
00769 {  
00770     return (volatile uint16_t*)k_mpu__mpops_addr;  
00771 }
```

References [k_mpu__mpops_addr](#).

8.37.4.11 mpu`mpsa`reg()

```
volatile uint32_t * mpu__mpsa_reg (  
    void )    [inline], [static]
```

Get pointer to MPSA (Region Search Address) register.

Returns

Volatile pointer to MPSA register (32-bit)

Since

Version 1.0.0

Definition at line 758 of file [rx72n_mpu_regs.h](#).

```
00759 {  
00760     return (volatile uint32_t*)k_mpu__mpsa_addr;  
00761 }
```

References [k_mpu__mpsa_addr](#).

8.37.4.12 mpu_page_to_reg()

```
uint32_t mpu_page_to_reg (
    uint32_t page)    [inline], [static]
```

Convert page number to RSPAGE/REPAGE register value.

Parameters

page	Page number (28 bits)
------	-----------------------

Returns

Register value with page number in bits [31:4]

Note

For REPAGE, caller must OR in access control and valid bits.

Example:

```
uint32_t rspage_val = mpu_page_to_reg(0x00001234);
uint32_t repage_val = mpu_page_to_reg(0x00001234) | k_repage_uac_rw | k_repage_v;
```

Since

Version 1.0.0

Definition at line 843 of file [rx72n_mpu_regs.h](#).

```
00844 {
00845     return (page « k_mpu_page_shift) & k_rspage_rspn_mask;
00846 }
```

References [k_mpu_page_shift](#), and [k_rspage_rspn_mask](#).

8.37.4.13 mpu_region()

```
volatile rx\_mpu\_region\_regs\_t * mpu_region (
    uint8_t region)    [inline], [static]
```

Get pointer to MPU region register pair.

Parameters

region	Region number (0-7)
--------	---------------------

Returns

Volatile pointer to region register structure

Precondition

`region < k_mpu_region_count` (8)

Note

Thread Safety: Safe - returns constant hardware address

Example:

```
// Configure region 0 to protect RAM (0x00000000-0x0007FFFF) as read-write
volatile rx_mpu_region_regs_t* r0 = mpu_region(k_mpu_region_0);
r0->rspage = 0x00000000; // Start at page 0
r0->repage = (0x0007FFF0) | k_repage_uac_rw | k_repage_v; // End at page 0x7FFF, RW, valid
```

Since

Version 1.0.0

Definition at line 669 of file `rx72n_mpu_regs.h`.

```
00670 {
00671     return (volatile rx_mpu_region_regs_t*)(k_mpu_region_base_addr + (region * k_mpu_region_size));
00672 }
```

References `k_mpu_region_base_addr`, and `k_mpu_region_size`.

8.37.4.14 mpu_repage_reg()

```
volatile uint32_t * mpu_repage_reg (
    uint8_t region) [inline], [static]
```

Get pointer to REPAGE register for a region.

Parameters

region	Region number (0-7)
--------	---------------------

Returns

Volatile pointer to REPAGE register (32-bit)

Since

Version 1.0.0

Definition at line 693 of file `rx72n_mpu_regs.h`.

```
00694 {
00695     return (volatile uint32_t*)(k_mpu_region_base_addr + (region * k_mpu_region_size) + 4U);
00696 }
```

References `k_mpu_region_base_addr`, and `k_mpu_region_size`.

8.37.4.15 mpu_rspage_reg()

```
volatile uint32_t * mpu_rspage_reg (
    uint8_t region)    [inline], [static]
```

Get pointer to RSPAGE register for a region.

Parameters

region	Region number (0-7)
--------	---------------------

Returns

Volatile pointer to RSPAGE register (32-bit)

Since

Version 1.0.0

Definition at line 681 of file [rx72n_mpu_regs.h](#).

```
00682 {
00683     return (volatile uint32_t*)(k_mpu_region_base_addr + (region * k_mpu_region_size));
00684 }
```

References [k_mpu_region_base_addr](#), and [k_mpu_region_size](#).

`k_mtu12p_off_tgrb` = 0x0AU , `k_mtu12p_off_tmdr3` = 0x11U , `k_mtu12p_off_tcncntlw` = 0x20U ,
`k_mtu12p_off_tgralw` = 0x24U ,
`k_mtu12p_off_tgrblw` = 0x28U , `k_mtu12p_struct_size` = 0x2CU }

Byte offsets of registers within `rx_mtu12_phase_regs_t`.

MTU3a Channel Capabilities

Channel	Counter	PWM	Phase Count	Complementary	Buffer
MTU0	16-bit	Yes	No	No	Yes
MTU1	16/32	Yes	Yes	No	No
MTU2	16/32	Yes	Yes	No	No
MTU3	16-bit	Yes	No	Yes (w/MTU4)	Yes
MTU4	16-bit	Yes	No	Yes (w/MTU3)	Yes

| MTU5 | 16-bit | Waveform generator (special) | No | | MTU6 | 16-bit | Yes | No | Yes (w/MTU7)
 | Yes | | MTU7 | 16-bit | Yes | No | Yes (w/MTU6) | Yes | | MTU8 | 32-bit | Yes | No | No | Yes |

STAR Motor Encoder Configuration

The STAR robot uses 4x brushed DC gearmotors with Hall effect quadrature encoders (341 PPR per revolution). MTU1 and MTU2 are configured in 32-bit cascaded phase counting mode for high-resolution position tracking:

$$\text{Position (revolutions)} = \frac{\text{TCNTLW}}{341 \times 4}$$

With 32-bit counter at 341 PPR x 4 edges = 1364 counts/rev:

- Range: +/-3,146,879 revolutions before overflow
- At 210 RPM max: 10.4 days continuous operation without wraparound

Clock Configuration

MTU timers derive their clock from PCLKA (Peripheral Clock A):

$$f_{timer} = \frac{f_{PCLKA}}{prescaler} = \frac{120 \text{ MHz}}{prescaler}$$

Available prescaler values: 1, 4, 16, 64, 256, 1024

PWM Frequency Calculation

For PWM mode 1 with compare match on TGRA:

$$f_{PWM} = \frac{f_{PCLKA}}{prescaler \times (TGRA + 1)}$$

Example: 20 kHz PWM at 120 MHz PCLKA, prescaler=1:

$$TGRA = \frac{120 \text{ MHz}}{1 \times 20 \text{ kHz}} - 1 = 5999$$

Hardware Reference

- RX72N Group User's Manual: Hardware, Chapter 24 (MTU3a)
- Section 24.2: Register Descriptions
- Section 24.3: Operations (Timer modes, PWM, Phase counting)
- Section 24.4: Interrupts

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion in inline functions
- Rule 2: [OK] Fixed loop bounds (N/A - register definitions only)
- Rule 3: [OK] Static allocation only (all definitions are compile-time)
- Rule 5: [OK] Static assertions verify register layout at compile time
- Rule 8: [OK] C23 typed enums eliminate preprocessor for constants
- Rule 10: [OK] Header compiles cleanly with -Wall -Wextra -Werror

SOLID Principles

- Single Responsibility: MTU register definitions only, no driver logic
- Open/Closed: Extend via new enums; don't modify existing values
- Interface Segregation: Separate structs for different channel types
- Dependency Inversion: Higher-level drivers depend on these abstractions

00670  *
00671  * @details
00672  * Extended register structure for MTU1 and MTU2 when operating in 32-bit
00673  * cascaded phase counting mode. This mode is ideal for quadrature encoder
00674  * applications requiring high-resolution position tracking over extended
00675  * ranges without software overflow handling.
00676  *
00677  * @par STAR Robot Encoder Configuration
00678  * The STAR robot uses 4x brushed DC gearmotors with Hall effect quadrature
00679  * encoders. MTU1 and MTU2 are cascaded to provide 32-bit position tracking:
00680  *
00681  * @verbatim
00682  * Encoder Signals          MTU1/MTU2 32-bit Cascaded Mode
00683  * -----
00684  *
00685  * Motor 1 (FL)          +-----+
00686  * +-----+          |          | 32-bit TCNTLW          |
00687  * | Hall A --->+> MTCLKA --->| [MTU2.TCNT | MTU1.TCNT]      |
00688  * | Hall B --->+> MTCLKB --->| Upper 16   Lower 16          |
00689  * +-----+          |          |
00690  * 341 PPR x 4 edges      | Position = TCNTLW / 1364        |
00691  * = 1364 counts/rev      | Range: +/-3.1M revolutions      |
00692  *          +-----+
00693  * @endverbatim
00694  *
00695  * @par 32-bit Cascaded Mode Benefits
00696  * - **Extended Range**: 232 counts vs 216 counts (65536x more range)
00697  * - **Atomic Access**: TCNTLW, TGRALW, TGRBLW are 32-bit atomic operations
00698  * - **No Race Conditions**: No need to disable interrupts during read
00699  * - **Hardware Implementation**: Zero software overhead for overflow tracking
00700  *
00701  * @par Position Calculation
00702  * For STAR robot Hall encoders (341 PPR, 4x quadrature = 1364 counts/rev):
00703  * @f[
00704  * \text{Position (revolutions)} = \frac{\text{TCNTLW}}{1364}
00705  * @f[
00706  * @f[
00707  * \text{Position (degrees)} = \frac{\text{TCNTLW}}{1364} \times 360\text{deg}
00708  * @f[
00709  *
00710  * @par Overflow Analysis
00711  * At maximum motor speed (210 RPM = 3.5 rev/sec):
00712  * @f[
00713  * t_{\text{overflow}} = \frac{2^{31}}{1364 \times 3.5} = 449,686 \text{ seconds} = 10.4 \text{ days}
00714  * @f[
00715  *
