POE3R4 bit definitions (add POE# flag conditions for MTU3/4 and MTU6/7).
- enum `poe3r5_bits_t` : `uint16_t` { `k_poe3r5_ic1addmt0ze` = 0x0002U , `k_poe3r5_ic2addmt0ze` = 0x0004U , `k_poe3r5_ic4addmt0ze` = 0x0010U , `k_poe3r5_ic5addmt0ze` = 0x0020U }
POE3R5 bit definitions (add POE# flag conditions for MTU0 pins).
- enum `alr1_bits_t` : `uint16_t` {
`k_alr1_olsg0a` = 0x0001U , `k_alr1_olsg0b` = 0x0002U , `k_alr1_olsg1a` = 0x0004U , `k_alr1_olsg1b` = 0x0008U ,
`k_alr1_olsg2a` = 0x0010U , `k_alr1_olsg2b` = 0x0020U , `k_alr1_olsen` = 0x0080U }
ALR1 bit definitions (active level for shoot-through detection).
- enum `poe3_mstpcr_t` : `uint32_t` { `k_poe3_mstpcra_bit` = (1U << 9U) }
POE3 module stop control bits.

Functions

- static volatile `uint16_t` * `poe3_icsr1_reg` (void)
Get pointer to ICSR1 register (POE0# control).
- static volatile `uint16_t` * `poe3_icsr2_reg` (void)
Get pointer to ICSR2 register (POE4# control).
- static volatile `uint16_t` * `poe3_icsr3_reg` (void)
Get pointer to ICSR3 register (POE8# control).
- static volatile `uint16_t` * `poe3_icsr4_reg` (void)
Get pointer to ICSR4 register (POE10# control).
- static volatile `uint16_t` * `poe3_icsr5_reg` (void)
Get pointer to ICSR5 register (POE11# control).
- static volatile `uint16_t` * `poe3_icsr6_reg` (void)
Get pointer to ICSR6 register (oscillation stop).
- static volatile `uint16_t` * `poe3_ocr1_reg` (void)
Get pointer to OCSR1 register (MTU3/4 shoot-through).
- static volatile `uint16_t` * `poe3_ocr2_reg` (void)
Get pointer to OCSR2 register (MTU6/7 shoot-through).
- static volatile `uint8_t` * `poe3_spoer_reg` (void)
Get pointer to SPOER register (software emergency stop).
- static volatile `uint8_t` * `poe3_poe3r1_reg` (void)
Get pointer to POE3R1 register (MTU0 pin control).
- static volatile `uint16_t` * `poe3_poe3r2_reg` (void)
Get pointer to POE3R2 register (MTU3/4 and MTU6/7 pin control).
- static volatile `uint16_t` * `poe3_poe3r4_reg` (void)
Get pointer to POE3R4 register (MTU3/4 and MTU6/7 additional POE# conditions).
- static volatile `uint16_t` * `poe3_poe3r5_reg` (void)

- Get pointer to POECR5 register (MTU0 additional POE# conditions).
- static volatile uint16_t * [poe3_alr1_reg](#) (void)
 - Get pointer to ALR1 register (active level).
- static volatile uint8_t * [poe3_m0selr1_reg](#) (void)
 - Get pointer to M0SELR1 register (MTU0 pin select 1).
- static volatile uint8_t * [poe3_m0selr2_reg](#) (void)
 - Get pointer to M0SELR2 register (MTU0 pin select 2).
- static volatile uint8_t * [poe3_m3selr_reg](#) (void)
 - Get pointer to M3SELR register (MTU3 pin select).
- static volatile uint8_t * [poe3_m4selr1_reg](#) (void)
 - Get pointer to M4SELR1 register (MTU4 pin select 1).
- static volatile uint8_t * [poe3_m4selr2_reg](#) (void)
 - Get pointer to M4SELR2 register (MTU4 pin select 2).
- static volatile uint8_t * [poe3_m6selr_reg](#) (void)
 - Get pointer to M6SELR register (MTU6 pin select).

8.41.1 Detailed Description

RX72N Port Output Enable 3 (POE3) Register Definitions.

Complete register definitions for the RX72N Port Output Enable 3 module. POE3 provides emergency output disable for MTU (Multi-Function Timer Pulse Unit) pins, enabling hardware-level motor protection.

POE3 Overview

- Emergency output disable for MTU0, MTU3/4, MTU6/7 pins
- Input signal detection (POE0#, POE4#, POE8#, POE10#, POE11#)
- Simultaneous conduction detection (shoot-through protection)
- Oscillation stop detection response
- Software-triggered high-impedance state

Target Pins for High-Impedance Control

Timer	Pins Controlled
MTU0	MTIOC0A, MTIOC0B, MTIOC0C, MTIOC0D
MTU3	MTIOC3B, MTIOC3D
MTU4	MTIOC4A, MTIOC4B, MTIOC4C, MTIOC4D
MTU6	MTIOC6B, MTIOC6D
MTU7	MTIOC7A, MTIOC7B, MTIOC7C, MTIOC7D

Register Organization (POE3 base: 0x0008C4C0)

Offset	Size	Register	Description
0x00	16	ICSR1	Input Level Control/Status 1 (POE0#)
0x02	16	OCSR1	Output Level Control/Status 1
0x04	16	ICSR2	Input Level Control/Status 2 (POE4#)
0x06	16	OCSR2	Output Level Control/Status 2
0x08	16	ICSR3	Input Level Control/Status 3 (POE8#)
0x0A	8	SPOER	Software Port Output Enable
0x0B	8	POECR1	Port Output Enable Control 1
0x0C	16	POECR2	Port Output Enable Control 2 (MTU3/4 b10:8, MTU6/7 b2:0)
0x10	16	POECR4	Port Output Enable Control 4 (ICxADD conditions MT34/MT67)
0x12	16	POECR5	Port Output Enable Control 5 (ICxADD conditions MT0)
0x16	16	ICSR4	Input Level Control/Status 4 (POE10#)
0x18	16	ICSR5	Input Level Control/Status 5 (POE11#)
0x1A	16	ALR1	Active Level Register 1
0x1C	16	ICSR6	Input Level Control/Status 6 (osc stop)
0x24	8	M0SELR1	MTU0 Pin Select 1
0x25	8	M0SELR2	MTU0 Pin Select 2
0x26	8	M3SELR	MTU3 Pin Select
0x27	8	M4SELR1	MTU4 Pin Select 1
0x28	8	M4SELR2	MTU4 Pin Select 2
0x2A	8	M6SELR	MTU6 Pin Select

NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: N/A (no loops)
- Rule 3: No dynamic memory allocation
- Rule 4: Short accessor functions
- Rule 5: Static assertions verify addresses
- Rule 6: Minimal scope
- Rule 7: N/A
- Rule 8: All constants use C23 typed enums
- Rule 9: No function pointers
- Rule 10: Compiles with -Wall -Wextra -Werror

8.41.2 Enumeration Type Documentation

8.41.2.1 alr1`bits``t`enum [alr1_bits_t](#) : uint16_t

ALR1 bit definitions (active level for shoot-through detection).

Register Layout (16-bit @ 0x0008C4DA)

Bits	Field	Description
0	OLSG0A	Active level for MTIOC3B/4A (group 0, positive)
1	OLSG0B	Active level for MTIOC3D/4C (group 0, negative)
2	OLSG1A	Active level for MTIOC3B/4A (group 1, positive)
3	OLSG1B	Active level for MTIOC3D/4C (group 1, negative)
4	OLSG2A	Active level for MTIOC4B (group 2, positive)
5	OLSG2B	Active level for MTIOC4D (group 2, negative)
6	-	Reserved
7	OLSEN	Active level select enable
15:↵ 8	-	Reserved

When OLSEN=0, active level determined by MTU.TOCR registers. When OLSEN=1, active level determined by OLSGnA/B bits (0=low, 1=high).

Since

Version 1.0.0

Enumerator

k_alr1_olsg0a	Active level for group 0 positive
k_alr1_olsg0b	Active level for group 0 negative
k_alr1_olsg1a	Active level for group 1 positive
k_alr1_olsg1b	Active level for group 1 negative
k_alr1_olsg2a	Active level for group 2 positive
k_alr1_olsg2b	Active level for group 2 negative
k_alr1_olsen	Active level select enable

Definition at line 536 of file [rx72n_poe3_regs.h](#).

```

00536      : uint16_t {
00537  k_alr1_olsg0a = 0x0001U, /**< Active level for group 0 positive */
00538  k_alr1_olsg0b = 0x0002U, /**< Active level for group 0 negative */

```

8.41.2.3 icsr_bits_t

enum [icsr_bits_t](#) : uint16_t

ICSR common bit definitions.

Register Layout (16-bit)

Bits	Field	Description
1:↔ 0	POEmM	POE# mode select
7:↔ 2	-	Reserved
8	PIEn	Port interrupt enable
9	POE8E	High-impedance enable (ICSR3 only)
11:10	-	Reserved
12	POEmF	POE# flag
15:13	-	Reserved

Since

Version 1.0.0

Enumerator

k_icsr_pie	Port Interrupt Enable (bit 8).
k_icsr_poef	POE# Flag (bit 12) - high-impedance request detected.
k_icsr3_poe8e	POE8 High-Impedance Enable (bit 9, ICSR3 only).

Definition at line 250 of file [rx72n_poe3_regs.h](#).

```
00250         : uint16_t {
00251     /** Common bits for ICSR1/2/3/4/5 */

00261 } icsr_bits_t;
```

8.41.2.4 icsr`poemode`

enum [icsr_poemode_t](#) : uint16_t

POE# Mode Select bits (POE0M/POE4M/POE8M/POE10M/POE11M).

Selects input detection mode for POE# pins. These bits can only be modified once after reset.

Note

Manual ref: Ch25 sections 25.2.1-25.2.5

Since

Version 1.0.0

Enumerator

k_icsr_poemode_falling_edge	Accept on falling edge of POE# input.
k_icsr_poemode_lowlevel_pclk8	Low-level sampling: 16 samples at PCLK/8.
k_icsr_poemode_lowlevel_pclk16	Low-level sampling: 16 samples at PCLK/16.
k_icsr_poemode_lowlevel_pclk128	Low-level sampling: 16 samples at PCLK/128.
k_icsr_poemode_mask	POEm mode select mask (bits 1:0).

Definition at line 216 of file [rx72n_poe3_regs.h](#).

```

00216         : uint16_t {

```

8.41.2.5 ocsr`bits`

enum [ocsr_bits_t](#) : uint16_t

OCSR bit definitions (simultaneous conduction detection).

Register Layout (16-bit)

Bits	Field	Description
7:0	-	Reserved
8	OIE _n	Simultaneous conduction interrupt enable
9	OCE _n	Simultaneous conduction high-impedance enable
14:10	-	Reserved
15	OSF _n	Simultaneous conduction flag

Used to detect and respond to simultaneous active-level output on complementary PWM pin pairs (shoot-through detection).

Note

Manual ref: Ch25 sections 25.2.7, 25.2.8

Since

Version 1.0.0

Enumerator

k_ocrs_oie	Simultaneous Conduction Interrupt Enable (bit 8).
k_ocrs_oce	Simultaneous Conduction High-Impedance Enable (bit 9). Can only be modified once after reset.
k_ocrs_osf	Simultaneous Conduction Flag (bit 15).

Definition at line 311 of file [rx72n_poe3_regs.h](#).

```

00311     : uint16_t {

```

8.41.2.6 poe3_addresses_t

```
enum poe3_addresses_t : uintptr_t
```

POE3 module addresses.

Base address and register addresses for POE3. All addresses verified against RX72N Hardware Manual Ch25.

Note

Addresses verified 2026-01-29 against manual section 25.2

Since

Version 1.0.0

Enumerator

k_poe3_base_addr	POE3 module base address.
k_poe3_icsr1_addr	ICSR1 address - Input Level Control/Status 1 (POE0#).
k_poe3_icsr2_addr	ICSR2 address - Input Level Control/Status 2 (POE4#).
k_poe3_icsr3_addr	ICSR3 address - Input Level Control/Status 3 (POE8#).
k_poe3_icsr4_addr	ICSR4 address - Input Level Control/Status 4 (POE10#).
k_poe3_icsr5_addr	ICSR5 address - Input Level Control/Status 5 (POE11#).
k_poe3_icsr6_addr	ICSR6 address - Input Level Control/Status 6 (osc stop).
k_poe3_ocr1_addr	OCSR1 address - Output Level Control/Status 1 (MTU3/4).
k_poe3_ocr2_addr	OCSR2 address - Output Level Control/Status 2 (MTU6/7).
k_poe3_spoer_addr	SPOER address - Software Port Output Enable Register.
k_poe3_poecr1_addr	POECR1 address - Port Output Enable Control 1 (MTU0).
k_poe3_poecr2_addr	POECR2 address - Port Output Enable Control 2 (MTU3/4).
k_poe3_poecr4_addr	POECR4 address - Port Output Enable Control 4 (MTU6/7).
k_poe3_poecr5_addr	POECR5 address - Port Output Enable Control 5 (additional).
k_poe3_alr1_addr	ALR1 address - Active Level Register 1.
k_poe3_m0selr1_addr	M0SELR1 address - MTU0 Pin Select 1.
k_poe3_m0selr2_addr	M0SELR2 address - MTU0 Pin Select 2.
k_poe3_m3selr_addr	M3SELR address - MTU3 Pin Select.
k_poe3_m4selr1_addr	M4SELR1 address - MTU4 Pin Select 1.
k_poe3_m4selr2_addr	M4SELR2 address - MTU4 Pin Select 2.
k_poe3_m6selr_addr	M6SELR address - MTU6 Pin Select.

```

8.41.2.13 spoer_bits_t

enum [spoer_bits_t](#) : uint8_t

SPOER bit definitions (software high-impedance control).

Register Layout (8-bit @ 0x0008C4CA)

Bit	Field	Description
0	MTUCH34HIZ	MTU3/4 high-impedance enable
1	MTUCH67HIZ	MTU6/7 high-impedance enable
2	MTUCH0HIZ	MTU0 high-impedance enable
7:↔ 3	-	Reserved

Software-triggered emergency stop for MTU pins. Writing 1 puts outputs in high-impedance state immediately.

Note

Manual ref: Ch25 section 25.2.10

Since

Version 1.0.0

Enumerator

k_spoer_mtuch34hiz	MTU3/4 Pins High-Impedance Enable (bit 0).
k_spoer_mtuch67hiz	MTU6/7 Pins High-Impedance Enable (bit 1).
k_spoer_mtuch0hiz	MTU0 Pins High-Impedance Enable (bit 2).

Definition at line 349 of file [rx72n_poe3_regs.h](#).

```

8.41.3 Function Documentation

8.41.3.1 poe3_alr1_reg()

```
volatile uint16_t * poe3_alr1_reg (
    void ) [inline], [static]
```

Get pointer to ALR1 register (active level).

Returns

Volatile pointer to ALR1 register (16-bit)

Since

Version 1.0.0

Definition at line 720 of file [rx72n_poe3_regs.h](#).

```
00721 {
00722     return (volatile uint16_t*)k_poe3_alr1_addr;
00723 }
```

References [k_poe3_alr1_addr](#).

8.41.3.2 poe3`icsr1`reg()

```
volatile uint16_t * poe3_icsr1_reg (
    void )    [inline], [static]
```

Get pointer to ICSR1 register (POE0# control).

Returns

Volatile pointer to ICSR1 register (16-bit)

Precondition

POE3 module stop bit (MSTPCRA.MSTPA9) must be cleared

Since

Version 1.0.0

Definition at line 583 of file [rx72n_poe3_regs.h](#).

```
00584 {
00585     return (volatile uint16_t*)k_poe3_icsr1_addr;
00586 }
```

8.41.3.3 poe3`icsr2`reg()

```
volatile uint16_t * poe3_icsr2_reg (
    void )    [inline], [static]
```

Get pointer to ICSR2 register (POE4# control).

Returns

Volatile pointer to ICSR2 register (16-bit)

Since

Version 1.0.0

Definition at line 593 of file [rx72n_poe3_regs.h](#).

```
00594 {
00595     return (volatile uint16_t*)k_poe3_icsr2_addr;

8.41.3.5 poe3_icsr4_reg()

```
volatile uint16_t * poe3_icsr4_reg (  
    void )    [inline], [static]
```

Get pointer to ICSR4 register (POE10# control).

Returns

Volatile pointer to ICSR4 register (16-bit)

Since

Version 1.0.0

Definition at line 613 of file [rx72n_poe3_regs.h](#).

```
00614 {

8.41.3.7 `poe3_icsr6_reg()`

```
volatile uint16_t * poe3_icsr6_reg (  
    void )    [inline], [static]
```

Get pointer to ICSR6 register (oscillation stop).

Returns

Volatile pointer to ICSR6 register (16-bit)

Since

Version 1.0.0

Definition at line 633 of file [rx72n_poe3_regs.h](#).

```
00634 {

00656 }
```

References [k_poe3_ocsr2_addr](#).

8.41.3.16 poe3_poecr1_reg()

```
volatile uint8_t * poe3_poecr1_reg (  
    void )    [inline], [static]
```

Get pointer to POECR1 register (MTU0 pin control).

Returns

Volatile pointer to POECR1 register (8-bit)

Since

Version 1.0.0

Definition at line 680 of file [rx72n_poe3_regs.h](#).

```
00681 {  
00682     return (volatile uint8_t*)k_poe3_poecr1_addr;  
00683 }
```

References [k_poe3_poecr1_addr](#).

8.41.3.17 poe3_poecr2_reg()

```
volatile uint16_t * poe3_poecr2_reg (  
    void )    [inline], [static]
```

Get pointer to POECR2 register (MTU3/4 and MTU6/7 pin control).

Returns

Volatile pointer to POECR2 register (16-bit)

Since

Version 1.0.0

Definition at line 690 of file [rx72n_poe3_regs.h](#).

```
00691 {  
00692     return (volatile uint16_t*)k_poe3_poecr2_addr;  
00693 }
```

References [k_poe3_poecr2_addr](#).

8.41.3.18 `poe3_poecr4_reg()`

```
volatile uint16_t * poe3_poecr4_reg (  
    void )    [inline], [static]
```

Get pointer to POECR4 register (MTU3/4 and MTU6/7 additional POE# conditions).

Returns

Volatile pointer to POECR4 register (16-bit)

Since

Version 1.0.0

Definition at line 700 of file [rx72n_poe3_regs.h](#).

```
00701 {  
00702     return (volatile uint16_t*)k_poe3_poecr4_addr;  
00703 }
```

8.41.3.19 `poe3_poecr5_reg()`

```
volatile uint16_t * poe3_poecr5_reg (  
    void )    [inline], [static]
```

Get pointer to POECR5 register (MTU0 additional POE# conditions).

Returns

Volatile pointer to POECR5 register (16-bit)

Since

Version 1.0.0

Definition at line 710 of file [rx72n_poe3_regs.h](#).

```
00711 {  
00712     return (volatile uint16_t*)k_poe3_poecr5_addr;  
00713 }
```

8.41.3.20 poe3`spoer`reg()

```
volatile uint8_t * poe3_spoer_reg (
    void ) [inline], [static]
```

Get pointer to SPOER register (software emergency stop).

Returns

Volatile pointer to SPOER register (8-bit)

Example - Emergency stop all MTU outputs:

```
// Immediately disable all MTU complementary PWM outputs
*poe3_spoer_reg() = k_spoer_mtuch0hiz | k_spoer_mtuch34hiz | k_spoer_mtuch67hiz;
```

Since

Version 1.0.0

Definition at line 670 of file rx72n_poe3_regs.h.

```
00671 {
00672     return (volatile uint8_t*)k_poe3_spoer_addr;
00673 }
```

POEG interrupt routing via GROUPBL2.

- enum `rx_poeg_group_regs_t` : `uintptr_t` { `k_poeg_grpbl2_addr` = 0x00087630 , `k_poeg_genbl2_addr` = 0x00087670 }

Memory-mapped addresses of the GROUPBL2 status/enable registers.

Functions

- static volatile `rx_poegg_regs_t` * `poegga` (void)
 Get pointer to POEG Group A registers.
- static volatile `rx_poegg_regs_t` * `poeggb` (void)
 Get pointer to POEG Group B registers.
- static volatile `rx_poegg_regs_t` * `poeggc` (void)
 Get pointer to POEG Group C registers.
- static volatile `rx_poegg_regs_t` * `poeggd` (void)
 Get pointer to POEG Group D registers.

8.43.1 Detailed Description

RX72N GPTW Port Output Enable (POEG) Register Definitions.

Register definitions for the POEG module which provides emergency PWM output disable functionality for the General PWM Timer (GPTW). The POEG is critical for motor control safety, allowing immediate PWM shutdown on fault detection.

Safety-Critical Emergency Stop System

STAR Project POEG Usage

Group	Assigned To	Trigger Source	Use Case
A	GPTW0 (Motor 0)	GTETRGA + Software	Front-left motor E-stop
B	GPTW1 (Motor 1)	GTETRGB + Software	Front-right motor E-stop
C	GPTW2 (Motor 2)	GTETRGC + Software	Back-right motor E-stop
D	GPTW3 (Motor 3)	GTETRGD + Software	Back-left motor E-stop

Key Features

- Emergency PWM output disable (immediate Hi-Z on fault)
- Multiple trigger sources: external pin, GPTW error, oscillation stop, software
- Digital noise filter on external trigger inputs
- Per-group independent control (4 groups for 4 motors)
- Interrupt generation on fault detection

Hardware Requirements

Parameter	Value	Notes
Base Address	0x0009E000	Group A base
Group Spacing	0x100 bytes	A=0x0000, B=0x0100, C=0x0200, D=0x0300
Module Stop	MSTPCRA.MSTPA7	Same as GPTW (shared)
Clock	PCLKB (60 MHz)	For noise filter sampling

NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: N/A (no loops in register definitions)
- Rule 3: No dynamic memory allocation
- Rule 4: All accessor functions are single-statement
- Rule 5: N/A (hardware layer)
- Rule 6: Minimal scope - inline accessors only
- Rule 7: N/A (no return values to check)
- Rule 8: All constants use C23 typed enums
- Rule 9: No function pointers
- Rule 10: Compiles with -Wall -Wextra -Werror

SOLID Principles

- S: Single responsibility - only POEG register definitions
- O: Open for extension via additional trigger configurations
- L: N/A (no inheritance hierarchy)
- I: Minimal interface - only necessary accessor functions
- D: N/A (hardware register layer)

Module Dependencies

- `<stdint.h>` - Fixed-width integer types
- `<stddef.h>` - `offsetof` macro for static assertions

8.43.2 Data Structure Documentation

8.43.2.1 struct rx72n_poeg_regs_t

POEG Group n Register Structure.

Each POEG group has a single 32-bit register (POEGGn) that controls emergency output disable for the associated GPTW channels. The register provides multiple trigger sources and status flags.

Memory Layout Table

Offset	Size	Field	Type	Description
0x00	4	poeggn	uint32↵ _t	Group n Setting Register
Total	4			

Emergency Stop Trigger Sources

1. External Pin (PIDF): GTETRGN pin input detection
2. GPTW Output Error (IOCF): Dead-time error or shoot-through detection
3. Oscillation Stop (OSTPF): Main clock failure detection
4. Software (SSF): Direct software emergency stop command

Configuration Example

```
// Enable software emergency stop and external trigger for Group A
volatile rx_poegg_regs_t* poeg_a = poegga();

// Enable external pin detection (one-time write after reset)
poeg_a->poeggn = k_poeg_pide_enable;

// Later, trigger emergency stop via software
poeg_a->poeggn |= k_poeg_ssf_stop; // Immediate PWM disable

// Clear emergency stop (after fault resolved)
poeg_a->poeggn &= ~k_poeg_ssf_stop; // Resume PWM
```

Invariant

sizeof(rx_poegg_regs_t) == 4 bytes

Note

All triggers are OR'd together - any trigger stops output

Warning

Enable bits (PIDE, IOCE, OSTPE) can only be written once after reset

Attention

Module stop bit shared with GPTW (MSTPCRA.MSTPA7)

8.43.3 Enumeration Type Documentation

8.43.3.1 rx_poeg_addresses_t

```
enum rx_poeg_addresses_t : uintptr_t
```

POEG group base addresses.

Base addresses for each POEG group (A-D). Each group controls emergency output disable for associated GPTW channels. Groups are spaced 0x100 bytes apart.

Memory Map

Address	Group	Controls	Description
0x0009E000	A	GPTW ch0-3	Emergency stop group A
0x0009E100	B	GPTW ch0-3	Emergency stop group B
0x0009E200	C	GPTW ch0-3	Emergency stop group C
0x0009E300	D	GPTW ch0-3	Emergency stop group D

00175      * @details Each POEG group has a 256-byte register block
00176      */
00177     k_poeg_group_spacing = 0x100,
00178 } rx_poeg_addresses_t;

```

8.43.3.2 rx`poeg`group`regs``t`

```
enum rx_poeg_group_regs_t : uintptr_t
```

Memory-mapped addresses of the GROUPBL2 status/enable registers.

Per RX72N HW manual R01UH0824EJ0111 Section 15.2 ("ICU Registers") the group interrupt registers are located in the ICU register block:

Register	Address	Purpose
GRPBL2	0x00087630	Group BL2 interrupt source status (R-only)
GENBL2	0x00087670	Group BL2 per-source enable (R/W)

Since

Version 1.0.0

Enumerator

k_poeg_grpbl2_addr	GRPBL2: sub-source status
k_poeg_genbl2_addr	GENBL2: sub-source enable

Definition at line 478 of file [rx72n_poeg_regs.h](#).

```
00478      : uintptr_t {
00479  k_poeg_grpbl2_addr = 0x00087630, /**< GRPBL2: sub-source status */
00480  k_poeg_genbl2_addr = 0x00087670, /**< GENBL2: sub-source enable */
00481 } rx_poeg_group_regs_t;
```

8.43.3.3 rx`poeg`interrupts``t`

```
enum rx_poeg_interrupts_t : uint16_t
```

POEG interrupt routing via GROUPBL2.

On RX72N, POEGGA/B/C/D interrupts are not dedicated vectors; they are sub-sources of the shared GROUPBL2 vector (IPR/IR/IER index 107). The individual source status and enables live in the GRPBL2 / GENBL2 registers at bits 7-10 respectively. Per RX72N HW manual R01UH0824EJ0111 Section 15.3 (Table 15.4) "Interrupt Vector Table".

Values previously encoded here (188-191) pointed at unassigned INTB slots and could never fire; corrected below.

Since

Version 1.0.0

Enumerator

k_poeg_irq_groupbl2_vector	GROUPBL2 shared ICU vector
----------------------------	----------------------------

k_poeg_grpbl2_bit_poeggai	GRPBL2/GENBL2 bit for POEGGAI

00371 } rx_poegg_bit_shifts_t;

```

8.43.3.5 rx`poegg`bits`r

enum [rx_poegg_bits_t](#) : uint32_t

POEGGn register bit definitions.

Configuration and status bit values for the POEG Group n Setting Register.

Flag Bits (Status/Control)

Bit	Name	Description
PIDF	b0	Port input detection flag (write 0 to clear)
IOCF	b1	GPTW output stop detected (write 0 to clear)
OSTPF	b2	Oscillation stop detected (write 0 to clear)
SSF	b3	Software stop flag (read/write)

Enable Bits (Write-Once After Reset)

Bit	Name	Description
PIDE	b4	Enable port input detection
IOCE	b5	Enable GPTW output stop detection
OSTPE	b6	Enable oscillation stop detection

Filter Configuration

NFCS	Clock	Sampling Delay
00	PCLKB/ $\frac{1}{1}$	~50 ns @ 60 MHz (3 samples)
01	PCLKB/ $\frac{1}{8}$	~400 ns @ 60 MHz (3 samples)
10	PCLKB/32	~1.6 μ s @ 60 MHz (3 samples)
11	PCLKB/128	~6.4 μ s @ 60 MHz (3 samples)

```

8.43.4 Function Documentation

8.43.4.1 poegga()

volatile rx_poegg_regs_t * poegga (

void) [inline], [static]

Get pointer to POEG Group A registers.

Returns a volatile pointer to POEG Group A register structure at address 0x0009E000. Use for emergency stop control of motor 0.

Returns

Volatile pointer to POEG Group A register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

GPTW/POEG module enabled (MSTPCRA.MSTPA7 = 0)

Postcondition

Pointer valid for lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

Example:

```
// Emergency stop motor 0
poegga()->poeggn |= k_poeg_ssf_stop;
```

See also

8.43.4.2 poeggb()

```
volatile rx_poegg_regs_t * poeggb (  
    void )    [inline], [static]
```

Get pointer to POEG Group B registers.

Returns a volatile pointer to POEG Group B register structure at address 0x0009E100. Use for emergency stop control of motor 1.

Returns

Volatile pointer to POEG Group B register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

GPTW/POEG module enabled (MSTPCRA.MSTPA7 = 0)

Postcondition

Pointer valid for lifetime of program execution

8.43.4.3 poeggc()

```
volatile rx_poegg_regs_t * poeggc (  
    void )    [inline], [static]
```

Get pointer to POEG Group C registers.

Returns a volatile pointer to POEG Group C register structure at address 0x0009E200. Use for emergency stop control of motor 2.

Returns

Volatile pointer to POEG Group C register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

GPTW/POEG module enabled (MSTPCRA.MSTPA7 = 0)

Postcondition

Pointer valid for lifetime of program execution

8.43.4.4 poeggd()

```
volatile rx_poegg_regs_t * poeggd (  
    void )    [inline], [static]
```

Get pointer to POEG Group D registers.

Returns a volatile pointer to POEG Group D register structure at address 0x0009E300. Use for emergency stop control of motor 3.

Returns

Volatile pointer to POEG Group D register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

GPTW/POEG module enabled (MSTPCRA.MSTPA7 = 0)

Postcondition

Pointer valid for lifetime of program execution

- Get pointer to PORTJ ODR register.

8.45.1 Detailed Description

RX72N PORT (GPIO) register definitions for digital pin control.

This file provides complete hardware register definitions for the RX72N's General Purpose I/O (GPIO) port peripheral. The PORT module controls digital pin direction, output state, input reading, and special modes like open-drain and pull-up resistors.

Critical Architecture Note

Warning

RX72N PORT registers are organized by REGISTER TYPE, not by PORT!

* Traditional MCU Layout	RX72N Layout (Type-Grouped)
* -----	* -----
* PORT0: PDR0, PODR0, ...	PDR: PDR0, PDR1, PDR2, ... (contiguous)
* PORT1: PDR1, PODR1, ...	PODR: PODR0, PODR1, PODR2, ... (contiguous)
* PORT2: PDR2, PODR2, ...	PIDR: PIDR0, PIDR1, PIDR2, ... (contiguous)
* ...	
* ...	

This struct provides a PORT-centric view with correct padding to handle the type-grouped hardware layout transparently.

System Architecture - STAR Robot GPIO Usage

Register Memory Map

Register	Base Address	Description
PDR	0x0008C000	Port Direction (0=input, 1=output)
PODR	0x0008C020	Port Output Data (output level)
PIDR	0x0008C040	Port Input Data (read pin state)
PMR	0x0008C060	Port Mode (0=GPIO, 1=peripheral)
ODR0/↔ 1	0x0008C080	Open Drain Control
PCR	0x0008C0C0	Pull-up Control
DSCR	0x0008C0E0	Drive Capacity Control

Register	Base Address	Description
DSCR2	0x0008C128	Drive Capacity Control 2

GPIO Configuration Example

```
// Configure PD0 as output (LED)
portd()->pmr &= ~(1 << 0); // GPIO mode (not peripheral)
portd()->pdr |= (1 << 0); // Output direction
portd()->podr |= (1 << 0); // Set high (LED on)

// Configure PA0 as input with pull-up (button)
porta()->pmr &= ~(1 << 0); // GPIO mode
porta()->pdr &= ~(1 << 0); // Input direction
porta()->pcr |= (1 << 0); // Enable pull-up

// Read button state
bool pressed = (porta()->pidr & (1 << 0)) == 0; // Active-low
```

Package Support

This file supports the 144-pin LQFP package (R5F572NNHxFB). Available ports and pins:

- Port 0: P00-P03, P05, P07 (6 pins)
- Port 1: P12-P17 (6 pins)
- Port 2: P20-P27 (full 8 pins)
- Port 3: P30-P37 (full 8 pins, P35 input-only)
- Port 4: P40-P47 (full 8 pins)
- Port 5: P50-P56 (7 pins)
- Port 6: P60-P67 (full 8 pins)
- Port 7: P70-P77 (full 8 pins)
- Port 8: P80-P83, P86-P87 (6 pins)
- Port 9: P90-P93 (4 pins)
- Port A: PA0-PA7 (full 8 pins)
- Port B: PB0-PB7 (full 8 pins)
- Port C: PC0-PC7 (full 8 pins)
- Port D: PD0-PD7 (full 8 pins)
- Port E: PE0-PE7 (full 8 pins)
- Port F: PF5 (1 pin)
- Port J: PJ3, PJ5 (2 pins)

Hardware Reference

- RX72N Group User's Manual: Hardware, Chapter 22 (I/O Ports)
- Section 22.3: Register Descriptions
- Section 22.4: Initialization

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion
- Rule 3: [OK] Static allocation only (all definitions compile-time)
- Rule 5: [OK] Static assertions verify register layout at compile time
- Rule 8: [OK] C23 typed enums eliminate preprocessor constants
- Rule 10: [OK] Header compiles cleanly with -Wall -Wextra -Werror

SOLID Principles

- Single Responsibility: GPIO register definitions only, no driver logic
- Open/Closed: Extend via new enums; don't modify existing values
- Interface Segregation: Single struct handles all port register types
- Dependency Inversion: Higher-level drivers depend on these abstractions

00127 * - RX72N Group User's Manual: Hardware, Chapter 22 (I/O Ports)
00128 * - Section 22.3: Register Descriptions
00129 * - Section 22.4: Initialization
00130 *
00131 * @par NASA Power of 10 Compliance
00132 * - Rule 1: [OK] No goto, setjmp, or recursion
00133 * - Rule 3: [OK] Static allocation only (all definitions compile-time)
00134 * - Rule 5: [OK] Static assertions verify register layout at compile time
00135 * - Rule 8: [OK] C23 typed enums eliminate preprocessor constants
00136 * - Rule 10: [OK] Header compiles cleanly with -Wall -Wextra -Werror
00137 *
00138 * @par SOLID Principles
00139 * - **Single Responsibility**: GPIO register definitions only, no driver logic
00140 * - **Open/Closed**: Extend via new enums; don't modify existing values
00141 * - **Interface Segregation**: Single struct handles all port register types
00142 * - **Dependency Inversion**: Higher-level drivers depend on these abstractions
00143 *

00377 * abstracting away the hardware's type-grouped layout. Padding bytes ensure
00378 * correct alignment between register types.
00379 *
00380 * @par Register Memory Layout (297 bytes total per port view)
00381 * @verbatim
00382 *   Offset  Size  Register  Description
00383 *   -----
00384 *   0x00    1    PDR       Port Direction (0=input, 1=output)
00385 *   0x01   31    [pad]     Reserved padding to PODR
00386 *   0x20    1    PODR      Port Output Data (0=low, 1=high)
00387 *   0x21   31    [pad]     Reserved padding to PIDR
00388 *   0x40    1    PIDR      Port Input Data (read-only, current pin level)
00389 *   0x41   31    [pad]     Reserved padding to PMR
00390 *   0x60    1    PMR       Port Mode (0=GPIO, 1=peripheral function)
00391 *   0x61   95    [pad]     Reserved (includes ODR space, see note below)
00392 *   0xC0    1    PCR       Pull-up Control (0=disabled, 1=enabled)
00393 *   0xC1   31    [pad]     Reserved padding to DSCR
00394 *   0xE0    1    DSCR      Drive Capacity (0=normal, 1=high drive)
00395 *   0xE1   71    [pad]     Reserved padding to DSCR2
00396 *   0x128   1    DSCR2     Drive Capacity 2 (enhanced high drive)
00397 * @endverbatim
00398 *
00399 * @note ODR (Open Drain Control) registers are NOT part of this structure.
00400 * They use word addressing and are accessed via separate port*_odr() functions
00401 * at hardware addresses: 0x0008C080 + (port_offset * 2)
00402 *
00403 * @par GPIO Configuration Sequence
00404 * Typical GPIO output configuration sequence:
00405 * 1. Set PMR = 0 (GPIO mode, not peripheral)
00406 * 2. Set PDR = 1 (output direction)
00407 * 3. Set PODR = desired output level
00408 * 4. Optionally set DSCR = 1 for high drive current
00409 *
00410 * Typical GPIO input configuration sequence:
00411 * 1. Set PMR = 0 (GPIO mode)
00412 * 2. Set PDR = 0 (input direction)
00413 * 3. Optionally set PCR = 1 for internal pull-up
00414 * 4. Read PIDR for current pin state
00415 *
00416 * @par LED Blink Example
00417 * @code
00418 * // Configure PD0 as output and blink LED
00419 * volatile rx_port_regs_t* pd = portd();
00420 *
00421 * pd->pmr &= ~(1 << 0); // GPIO mode
00422 * pd->pdr |= (1 << 0); // Output direction
00423 *
00424 * while (1) {
00425 *     pd->podr ^= (1 << 0); // Toggle LED
00426 *     delay_ms(500);
00427 * }
00428 * @endcode
00429 *
00430 * @par Button Read Example
00431 * @code
00432 * // Configure PA0 as input with pull-up and read button
00433 * volatile rx_port_regs_t* pa = porta();
00434 *
00435 * pa->pmr &= ~(1 << 0); // GPIO mode
00436 * pa->pdr &= ~(1 << 0); // Input direction
00437 * pa->pcr |= (1 << 0); // Enable pull-up (button connects to GND)
00438 *
00439 * bool pressed = ((pa->pidr & (1 << 0)) == 0); // Active-low
00440 * @endcode
00441 *
00442 * @invariant Structure size must be exactly 297 bytes (0x129)
00443 * @invariant All register offsets must match hardware layout exactly
00444 * @invariant Structure must be packed to ensure correct padding sizes

```

```

00445 *
00446 * @note Uses __attribute__((packed)) to prevent compiler padding optimizations
00447 *
00448 * @warning This structure assumes PORT0 padding layout (offset=0x00).
00449 * The type-grouped hardware layout places ODR at varying struct offsets
00450 * for different ports (0x80 + port_offset*2). ODR is accessed via
00451 * separate port*_odr() functions to ensure correct word addressing.
00452 *
00453 * @warning Do not use sizeof() for port address calculations; use offset enum
00454 *
00455 * @note PORT3 lacks DSCR (has only DSCR2).
00456 * @note PORT4 lacks both DSCR and DSCR2 (hardware limitation).
00457 * @note All other ports (0-2, 5, A-E, J) have both DSCR and DSCR2.
00458 *
00459 * @see rx_port_reg_bases_t for register base addresses
00460 * @see rx_port_offsets_t for port offset values
00461 * @see RX72N Hardware Manual Section 22.3 (Register Descriptions)

Functions

- static `rx_ram_regs_t * ram_regs` (void)
Get pointer to RAM control registers.
- static `rx_exram_regs_t * exram_regs` (void)
Get pointer to Expansion RAM control registers.

8.47.1 Detailed Description

RX72N RAM and Expansion RAM register definitions.

This header defines register structures and addresses for the two parity-checked static RAM regions on the RX72N MCU:

- RAM (512 KB at 0x00000000-0x0007FFFF): 1-bit parity checking, Memory Bus 1
- Expansion RAM (512 KB at 0x00800000-0x0087FFFF): 1-bit parity checking, Memory Bus 3

The ECC-protected 32 KB region (ECCRAM) has its own header, [rx72n_eccram_regs.h](#), since its control block and usage pattern differ substantially from the parity-only regions.

All register addresses are verified against the RX72N User's Manual Chapter 60.

Memory Map (from Manual Ch60, Table 60.1):

Type	Address Range	Size	Error Checking
RAM	0x00000000 - 0x0007FFFF	512 KB	1-bit parity detection
Expansion RAM	0x00800000 - 0x0087FFFF	512 KB	1-bit parity detection

Register Base Addresses:

- RAM registers: 0x00081200
- Expansion RAM registers: 0x00081240

Note

All RAM regions operate after reset without module stop.

Data is NOT retained during deep software standby mode.

When ICLK > 120 MHz, MEMWAIT must be set to 1 for Expansion RAM.

NASA Power of 10 Compliance:

- Rule 5: Static assertions verify all register addresses
- Rule 8: All constants use typed enums, no macros for values

8.47.3.4 rx_exramsts_bits_t

```
enum rx_exramsts_bits_t : uint8_t
```

EXRAMSTS register bit definitions.

Expansion RAM Error Status Flag from Manual Ch60, section 60.2.6.

Enumerator

k_rx_exramsts_exramerr_bit	Expansion RAM error flag bit position.
k_rx_exramsts_exramerr_mask	Expansion RAM error flag mask.

Definition at line 215 of file [rx72n_ram_regs.h](#).

```
00215         : uint8_t {
00216     /** @brief Expansion RAM error flag bit position */
00217     k_rx_exramsts_exramerr_bit = 0,
00218     /** @brief Expansion RAM error flag mask */
00219     k_rx_exramsts_exramerr_mask = 0x01,
00220 } rx_exramsts_bits_t;
```

8.47.3.5 rx_ram_mstpcrc_bits_t

```
enum rx_ram_mstpcrc_bits_t : uint32_t
```

MSTPCRC register bits for parity-RAM module stop control.

Module stop control from Manual Ch60, section 60.4.1. Setting these bits stops clock supply to the respective RAM areas.

Note

The MSTPC6 bit for ECCRAM lives in [rx72n_eccram_regs.h](#).

Enumerator

k_rx_mstpcrc_ram_bit	MSTPC0 - RAM module stop bit (stops RAM clock).
k_rx_mstpcrc_exram_bit	MSTPC2 - Expansion RAM module stop bit.

Definition at line 253 of file [rx72n_ram_regs.h](#).

```
00253         : uint32_t {
00254     /** @brief MSTPC0 - RAM module stop bit (stops RAM clock) */
00255     k_rx_mstpcrc_ram_bit = 0,
00256     /** @brief MSTPC2 - Expansion RAM module stop bit */
00257     k_rx_mstpcrc_exram_bit = 2,
00258 } rx_ram_mstpcrc_bits_t;
```

8.47.3.6 rx_ram_reg_addr_t

```
enum rx_ram_reg_addr_t : uintptr_t
```

RAM control register base addresses.

Defines register base addresses for RAM control, verified against Ch60.

Enumerator

k_rx_ram_reg_base_addr	RAM control registers base address.
k_rx_exram_reg_base_addr	Expansion RAM control registers base address.

Definition at line 94 of file [rx72n_ram_regs.h](#).

```
00094 : uintptr_t {
00095 /** @brief RAM control registers base address */
00096 k_rx_ram_reg_base_addr = 0x00081200,
00097 /** @brief Expansion RAM control registers base address */
00098 k_rx_exram_reg_base_addr = 0x00081240,
00099 } rx_ram_reg_addr_t;
```

8.47.3.7 rx_ram_reg_offset_t

```
enum rx_ram_reg_offset_t : uint8_t
```

RAM register offsets from base 0x00081200.

Offsets verified against Manual Ch60, sections 60.2.1-60.2.4.

Enumerator

k_rx_ram_offset_rammode	RAMMODE @ 0x00081200 - RAM Operating Mode Control Register.
k_rx_ram_offset_ramsts	RAMSTS @ 0x00081201 - RAM Error Status Register.
k_rx_ram_offset_ramprcr	RAMPRCR @ 0x00081204 - RAM Protection Register.
k_rx_ram_offset_ramecad	RAMECAD @ 0x00081208 - RAM Error Address Capture Register.

Definition at line 112 of file [rx72n_ram_regs.h](#).

```
00112 : uint8_t {
00113 /** @brief RAMMODE @ 0x00081200 - RAM Operating Mode Control Register */
00114 k_rx_ram_offset_rammode = 0x00,
00115 /** @brief RAMSTS @ 0x00081201 - RAM Error Status Register */
00116 k_rx_ram_offset_ramsts = 0x01,
00117 /** @brief RAMPRCR @ 0x00081204 - RAM Protection Register */
00118 k_rx_ram_offset_ramprcr = 0x04,
00119 /** @brief RAMECAD @ 0x00081208 - RAM Error Address Capture Register */
00120 k_rx_ram_offset_ramecad = 0x08,
00121 } rx_ram_reg_offset_t;
```

8.47.3.8 rx_ram_region_addr_t

```
enum rx_ram_region_addr_t : uintptr_t
```

RAM region base addresses and sizes.

Defines the address ranges for all RAM regions on the RX72N. These are from Manual Ch60, Table 60.1.

Enumerator

k_rx_ram_base_addr	RAM start address (512 KB, Memory Bus 1).
k_rx_ram_end_addr	RAM end address (inclusive).
k_rx_ram_size	RAM size in bytes. 512 KB
k_rx_exram_base_addr	Expansion RAM start address (512 KB, Memory Bus 3).
k_rx_exram_end_addr	Expansion RAM end address (inclusive).
k_rx_exram_size	Expansion RAM size in bytes. 512 KB

Definition at line 67 of file rx72n_ram_regs.h.

```
00067     : uintptr_t {
00068     /** @brief RAM start address (512 KB, Memory Bus 1) */
00069     k_rx_ram_base_addr = 0x00000000,
00070     /** @brief RAM end address (inclusive) */
00071     k_rx_ram_end_addr = 0x0007FFFF,
00072     /** @brief RAM size in bytes */
00073     k_rx_ram_size = 0x00080000, /**< 512 KB */
00074
00075     /** @brief Expansion RAM start address (512 KB, Memory Bus 3) */
00076     k_rx_exram_base_addr = 0x00800000,
00077     /** @brief Expansion RAM end address (inclusive) */
00078     k_rx_exram_end_addr = 0x0087FFFF,
00079     /** @brief Expansion RAM size in bytes */
00080     k_rx_exram_size = 0x00080000, /**< 512 KB */
00081 } rx_ram_region_addr_t;
```

8.47.3.9 rx_rammode_bits_t

```
enum rx_rammode_bits_t : uint8_t
```

RAMMODE register bit definitions.

RAM Operating Mode Select bits from Manual Ch60, section 60.2.1.

Enumerator

k_rx_rammode_parity_disabled	Parity checking disabled (RAMMODE[1:0] = 00b).
k_rx_rammode_parity_enabled	Parity checking enabled (RAMMODE[1:0] = 01b).

Definition at line 152 of file rx72n_ram_regs.h.

```
00152     : uint8_t {
00153     /** @brief Parity checking disabled (RAMMODE[1:0] = 00b) */
00154     k_rx_rammode_parity_disabled = 0x00,
00155     /** @brief Parity checking enabled (RAMMODE[1:0] = 01b) */
00156     k_rx_rammode_parity_enabled = 0x01,
00157 } rx_rammode_bits_t;
```

8.47.3.10 rx`ramprcr`bits`t

```
enum rx_ramprcr_bits_t : uint8_t
```

RAMPRCR register bit definitions.

RAM Protection Register from Manual Ch60, section 60.2.4. Write 0xF1 to enable writing to RAMMODE register.

Enumerator

k_rx_ramprcr_ramprcr_bit	RAMPRCR bit position (enable RAMMODE writes).
k_rx_ramprcr_ramprcr_mask	RAMPRCR enable mask.
k_rx_ramprcr_key	Key byte: KW[6:0] = 1111000b placed in bits[7:1] of register.
k_rx_ramprcr_unlock	Complete value to enable RAMMODE writes (key + RAMPRCR=1).
k_rx_ramprcr_lock	Complete value to disable RAMMODE writes (key + RAMPRCR=0).

Definition at line 181 of file [rx72n_ram_regs.h](#).

```
00181         : uint8_t {
00182     /** @brief RAMPRCR bit position (enable RAMMODE writes) */
00183     k_rx_ramprcr_ramprcr_bit = 0,
00184     /** @brief RAMPRCR enable mask */
00185     k_rx_ramprcr_ramprcr_mask = 0x01,
00186     /** @brief Key byte: KW[6:0] = 1111000b placed in bits[7:1] of register */
00187     k_rx_ramprcr_key = 0xF0,
00188     /** @brief Complete value to enable RAMMODE writes (key + RAMPRCR=1) */
00189     k_rx_ramprcr_unlock = 0xF1,
00190     /** @brief Complete value to disable RAMMODE writes (key + RAMPRCR=0) */
00191     k_rx_ramprcr_lock = 0xF0,
00192 } rx_ramprcr_bits_t;
```

8.47.3.11 rx`ramsts`bits`t

```
enum rx_ramsts_bits_t : uint8_t
```

RAMSTS register bit definitions.

RAM Error Status Flag from Manual Ch60, section 60.2.2.

Enumerator

k_rx_ramsts_ramerr_bit	RAM error flag bit position.
k_rx_ramsts_ramerr_mask	RAM error flag mask.

Definition at line 166 of file [rx72n_ram_regs.h](#).

```
00166         : uint8_t {
00167     /** @brief RAM error flag bit position */

00169     /** @brief RAM error flag mask */
00170     k_rx_ramsts_ramerr_mask = 0x01,
00171 } rx_ramsts_bits_t;
```

8.47.4 Function Documentation

8.47.4.1 exram_regs()

```
rx_exram_regs_t * exram_regs (  
    void )    [inline], [static]
```

Get pointer to Expansion RAM control registers.

Returns a pointer to the Expansion RAM control register structure at 0x00081240.

Returns

Pointer to [rx_exram_regs_t](#) structure

Example:

```
// Enable parity checking for Expansion RAM  
exram_regs()->exramprcr = k_rx_exramprcr_unlock; // Unlock  
exram_regs()->exrammode = k_rx_exrammode_parity_enabled;  
exram_regs()->exramprcr = k_rx_exramprcr_lock; // Lock
```

Definition at line 339 of file [rx72n_ram_regs.h](#).

```
00340 {  
00341     return (rx_exram_regs_t*)k_rx_exram_reg_base_addr;  
00342 }
```

References [k_rx_exram_reg_base_addr](#).

8.47.4.2 ram_regs()

```
rx_ram_regs_t * ram_regs (  
    void )    [inline], [static]
```

Get pointer to RAM control registers.

Returns a pointer to the RAM control register structure at 0x00081200.

Returns

Pointer to [rx_ram_regs_t](#) structure

Example:

```
// Enable parity checking for RAM  
ram_regs()->ramprcr = k_rx_ramprcr_unlock; // Unlock  
ram_regs()->rammode = k_rx_rammode_parity_enabled;  
ram_regs()->ramprcr = k_rx_ramprcr_lock; // Lock
```

Definition at line 318 of file [rx72n_ram_regs.h](#).

```
00319 {  
00320     return (rx_ram_regs_t*)k_rx_ram_reg_base_addr;  
00321 }
```

00001 /**
00002  * @file rx72n_ram_regs.h
00003  * @brief RX72N RAM and Expansion RAM register definitions
00004  *
00005  * @details
00006  * This header defines register structures and addresses for the two
00007  * parity-checked static RAM regions on the RX72N MCU:
00008  *
00009  * - **RAM** (512 KB at 0x00000000-0x0007FFFF): 1-bit parity checking, Memory Bus 1
00010  * - **Expansion RAM** (512 KB at 0x00800000-0x0087FFFF): 1-bit parity checking, Memory Bus 3
00011  *
00012  * The ECC-protected 32 KB region (ECCRAM) has its own header,
00013  * rx72n_eccram_regs.h, since its control block and usage pattern
00014  * differ substantially from the parity-only regions.
00015  *
00016  * All register addresses are verified against the RX72N User's Manual Chapter 60.
00017  *
00018  * @par Memory Map (from Manual Ch60, Table 60.1):
00019  * | Type | Address Range | Size | Error Checking |
00020  * |-----|-----|-----|-----|
00021  * | RAM | 0x00000000 - 0x0007FFFF | 512 KB | 1-bit parity detection |
00022  * | Expansion RAM | 0x00800000 - 0x0087FFFF | 512 KB | 1-bit parity detection |
00023  *
00024  * @par Register Base Addresses:
00025  * - RAM registers: 0x00081200
00026  * - Expansion RAM registers: 0x00081240
00027  *
00028  * @note All RAM regions operate after reset without module stop.
00029  * @note Data is NOT retained during deep software standby mode.
00030  * @note When ICLK > 120 MHz, MEMWAIT must be set to 1 for Expansion RAM.
00031  *
00032  * @par NASA Power of 10 Compliance:
00033  * - Rule 5: Static assertions verify all register addresses
00034  * - Rule 8: All constants use typed enums, no macros for values
00035  *
00036  * @see rx72n_eccram_regs.h ECC-protected RAM definitions
00037  * @see RX72N User's Manual Chapter 60 (RAM)
00038  * @see RX72N User's Manual Chapter 11 (Low Power Consumption) for MSTPCRC
00039  * @see RX72N User's Manual Section 9.2.2 (MEMWAIT register)

Include dependency graph for rx72n_regs.h:

RX72N Hardware Register Definitions - Main Aggregator Header.

Purpose: Simplifies HAL implementation by consolidating all register headers. Based On: Renesas RX72N Group User's Manual: Hardware (Rev.1.00, Feb 2019) Target MCU: R5F572NNHxFB (144-pin LFQFP, 4MB Flash, 512KB SRAM)

This file acts as a facade, grouping related peripheral register definitions:

8.49.1.3 Included Peripheral Register Files

Header File	Peripheral	Base Address	Purpose in STAR
rx72n_system_regs.h	System Control	0x00080000	Clock config, module stop control
rx72n_port_regs.h	GPIO Ports	0x0008C000	Digital I/O, motor control signals
rx72n_adc_regs.h	S12AD0/1	0x00089000	Current sensing, voltage measurement
rx72n_sci_regs.h	SCI0-12	0x0008A000	UART debug output (SCI9)
rx72n_riic_regs.h	RIIC0-2	0x00088300	I2C sensors (IMU)
rx72n_rspi_regs.h	RSPI0-2	0x000D0000	SPI: RPi5 comm (RSPI1 not used)
rx72n_cmt_regs.h	CMT0-3	0x00088000	ThreadX system tick (100 Hz)
rx72n_icu_regs.h	ICU	0x00087000	Interrupt routing and priorities
rx72n_iwdt_regs.h	IWDT	0x00088030	Independent watchdog (safety)
rx72n_wdt_regs.h	WDT	0x00088020	Watchdog timer
rx72n_crc_regs.h	CRC	0x00088280	Hardware CRC-32 (Protocol validation)
rx72n_usb_regs.h	USB0	0x000A0000	USB 2.0 full-speed device mode
rx72n_mtu_regs.h	MTU0-4	0x000C1200	Quadrature encoder counting
rx72n_gptw_regs.h	GPTW0-3	0x000C2000	High-resolution PWM (motors)
rx72n_mpc_regs.h	MPC	0x0008C100	Pin function multiplexing
rx72n_flash_regs.h	FLASH	0x007FE000	Flash programming, ROM cache
rx72n_ram_regs.h	RAM	0x00081200	RAM/EXRAM/ECCRAM control, parity, ECC
rx72n_clock.h	Clock Defs	-	Frequency constants (240 MHz)

8.49.1.4 RX72N Memory Map (Relevant Sections)

8.49.1.5 Usage Guidelines

8.49.1.5.1 Recommended Practice

Application code should NOT include this file directly. Instead, use the HAL API provided by [hardware.h](#) which abstracts register access with type-safe functions.

```

// WRONG - Direct register access (bypasses HAL safety checks)
#include "rx72n_regs.h"
PORT3.PDR.BIT.B0 = 1; // No validation, no error checking

// CORRECT - Use HAL API (safe, validated, portable)
#include "hardware.h"
gpio_set_output(k_port_c_pin_0); // Type-safe, validated, error-checked

```

8.49.1.5.2 When Direct Register Access is Acceptable

Only use direct register access when:

1. Implementing new HAL drivers (inside lib/rx_hal/src/)
2. Low-level initialization code (clock setup, early boot)
3. Interrupt handlers requiring minimal latency
4. Performance-critical code after profiling shows HAL overhead is significant

8.49.1.5.3 Register Access Pattern (for HAL implementation)

```
#include "rx72n_regs.h"

// Example: Configure CMT0 for 10ms period @ 240 MHz
void timer_init(void) {
    // 1. Enable module clock
    SYSTEM.MSTPCRA.BIT.MSTPA15 = 0; // CMT0 module stop release

    // 2. Stop timer
    CMT0.CMSTR.BIT.STR = 0;

    // 3. Configure
    CMT0.CMCR.WORD = 0x0042; // PCLK/128, compare match interrupt
    CMT0.CMCOR = 18750; // 240MHz / 128 / 100Hz - 1

    // 4. Start timer
    CMT0.CMSTR.BIT.STR = 1;
}
```

8.49.1.6 Design Rationale

8.49.1.6.1 Why Separate Register Headers?

Approach	Pros	Cons
Single monolithic file	Easy to find everything	>10,000 lines, slow compilation, merge conflicts
Separate files (this approach)	Modular, fast compilation, maintainable	Requires aggregator (this file)

8.49.1.6.2 Benefits of This Architecture

1. Compile-time optimization: Only includes necessary peripheral headers
2. Maintainability: Each peripheral in separate file (~200-500 lines each)
3. Testability: Individual headers can be tested/validated independently
4. Team collaboration: Multiple developers can work on different peripherals without conflicts

8.49.1.7 Register Access Performance

Operation	Cycles @ 240 MHz	Time	Notes
Single register write	1-2	4-8 ns	Direct memory store
Single register read	1-2	4-8 ns	Direct memory load
Bit-field write	4-6	17-25 ns	Read-modify-write sequence
Protected register write	10-15	42-63 ns	Includes unlock/lock sequence

8.49.1.8 Safety Considerations

8.49.1.8.1 Write-Protected Registers

Some critical registers require unlock sequence before modification:

- System registers: Clock config, module stop control
- Port function selection: MPC registers
- Watchdog: WDT/IWDT configuration

Always use HAL functions for these registers to ensure correct unlock/lock sequence.

8.49.1.8.2 Reserved Bits

- Never write to reserved bits (may cause undefined behavior or peripheral malfunction)
- Read as 0, write as 0 for all reserved bits
- HAL functions handle this automatically

8.49.1.9 Dependencies

- Individual peripheral register headers (rx72n*_regs.h)
- <stdint.h> for fixed-width integer types (uint8_t, uint16_t, uint32_t)

NASA Power of 10 Compliance:

- Rule 1 [YES]: No goto, setjmp, recursion (pure header file with includes and definitions)
- Rule 2 [N/A]: No loops (header file only)
- Rule 3 [YES]: No dynamic allocation (register definitions are compile-time constants)
- Rule 4 [N/A]: No functions (header file only)
- Rule 5 [N/A]: No functions to validate (header file only)
- Rule 6 [YES]: All definitions at file scope (standard C practice)
- Rule 7 [N/A]: No function calls (header file only)
- Rule 8 [YES]: No macros except include guards
- Rule 9 [YES]: Register definitions use typed pointers (single level of dereferencing)
- Rule 10 [YES]: Compiles without warnings with -Wall -Wextra -Werror

SOLID Principles:

- S (Single Responsibility): Only aggregates register definitions (no logic, no functions)
- O (Open/Closed): New peripherals added by including new headers (no modification needed)
- L (Liskov Substitution): N/A (no polymorphism in C header files)
- I (Interface Segregation): Each peripheral in separate header (users include only what they need)
- D (Dependency Inversion): HAL ([hardware.h](#)) depends on this abstraction, not concrete implementations

Module Dependencies:

```
rx72n_regs.h (this file)
+--> rx72n_system_regs.h
+--> rx72n_port_regs.h
+--> rx72n_adc_regs.h
+--> rx72n_sci_regs.h
+--> rx72n_riic_regs.h
+--> rx72n_rspi_regs.h
+--> rx72n_cmt_regs.h
+--> rx72n_icu_regs.h
+--> rx72n_iwdt_regs.h
+--> rx72n_wdt_regs.h
+--> rx72n_crc_regs.h

00107 * 0xFFFFFFFF +-----+
00108 * ```
00109 *
00110 * ## Usage Guidelines
00111 *
00112 * ### Recommended Practice
00113 * **Application code should NOT include this file directly.** Instead, use the HAL API
00114 * provided by `hardware.h` which abstracts register access with type-safe functions.
00115 *
00116 * @code{.c}
00117 * // WRONG - Direct register access (bypasses HAL safety checks)
00118 * #include "rx72n_regs.h"
00119 * PORT3.PDR.BIT.B0 = 1; // No validation, no error checking
00120 *
00121 * // CORRECT - Use HAL API (safe, validated, portable)
00122 * #include "hardware.h"
00123 * gpio_set_output(k_port_c_pin_0); // Type-safe, validated, error-checked
00124 * @endcode
00125 *
00126 * ### When Direct Register Access is Acceptable
00127 * Only use direct register access when:
00128 * 1. Implementing new HAL drivers (inside lib/rx_hal/src/)
00129 * 2. Low-level initialization code (clock setup, early boot)
00130 * 3. Interrupt handlers requiring minimal latency
00131 * 4. Performance-critical code after profiling shows HAL overhead is significant
00132 *
00133 * ### Register Access Pattern (for HAL implementation)
00134 * @code{.c}
00135 * #include "rx72n_regs.h"
00136 *
00137 * // Example: Configure CMT0 for 10ms period @ 240 MHz
00138 * void timer_init(void) {
00139 *     // 1. Enable module clock
00140 *     SYSTEM.MSTPCRA.BIT.MSTPA15 = 0; // CMT0 module stop release
00141 *
00142 *     // 2. Stop timer
00143 *     CMT0.CMSTR.BIT.STR = 0;
00144 *
00145 *     // 3. Configure
00146 *     CMT0.CMCR.WORD = 0x0042; // PCLK/128, compare match interrupt
00147 *     CMT0.CMCOR = 18750; // 240MHz / 128 / 100Hz - 1
00148 *
00149 *     // 4. Start timer
00150 *     CMT0.CMSTR.BIT.STR = 1;
00151 * }
00152 * @endcode
00153 *
00154 * ## Design Rationale
00155 *
00156 * ### Why Separate Register Headers?
00157 * | Approach | Pros | Cons |
00158 * |-----|-----|-----|
00159 * | **Single monolithic file** | Easy to find everything | >10,000 lines, slow compilation, merge conflicts |
00160 * | **Separate files (this approach)** | Modular, fast compilation, maintainable | Requires aggregator (this file) |
00161 *
00162 * ### Benefits of This Architecture
00163 * 1. **Compile-time optimization**: Only includes necessary peripheral headers
00164 * 2. **Maintainability**: Each peripheral in separate file (~200-500 lines each)
00165 * 3. **Testability**: Individual headers can be tested/validated independently
00166 * 4. **Team collaboration**: Multiple developers can work on different peripherals without conflicts
00167 *
00168 * ## Register Access Performance
00169 *

```

```

00170 * | Operation | Cycles @ 240 MHz | Time | Notes |
00171 * |-----|-----|-----|-----|
00172 * | Single register write | 1-2 | 4-8 ns | Direct memory store |
00173 * | Single register read | 1-2 | 4-8 ns | Direct memory load |
00174 * | Bit-field write | 4-6 | 17-25 ns | Read-modify-write sequence |
00175 * | Protected register write | 10-15 | 42-63 ns | Includes unlock/lock sequence |
00176 *
00177 * ## Safety Considerations
00178 *
00179 * ### Write-Protected Registers
00180 * Some critical registers require unlock sequence before modification:
00181 * - **System registers**: Clock config, module stop control
00182 * - **Port function selection**: MPC registers
00183 * - **Watchdog**: WDT/IWDT configuration
00184 *
00185 * **Always use HAL functions** for these registers to ensure correct unlock/lock sequence.
00186 *
00187 * ### Reserved Bits
00188 * - **Never write to reserved bits** (may cause undefined behavior or peripheral malfunction)
00189 * - **Read as 0, write as 0** for all reserved bits
00190 * - HAL functions handle this automatically
00191 *
00192 * ## Dependencies
00193 * - Individual peripheral register headers (rx72n_*_regs.h)
00194 * - `<stdint.h>` for fixed-width integer types (uint8_t, uint16_t, uint32_t)
00195 *
00196 * @par NASA Power of 10 Compliance:
00197 * - **Rule 1 [YES]**: No goto, setjmp, recursion (pure header file with includes and definitions)
00198 * - **Rule 2 [N/A]**: No loops (header file only)
00199 * - **Rule 3 [YES]**: No dynamic allocation (register definitions are compile-time constants)
00200 * - **Rule 4 [N/A]**: No functions (header file only)
00201 * - **Rule 5 [N/A]**: No functions to validate (header file only)
00202 * - **Rule 6 [YES]**: All definitions at file scope (standard C practice)
00203 * - **Rule 7 [N/A]**: No function calls (header file only)
00204 * - **Rule 8 [YES]**: No macros except include guards
00205 * - **Rule 9 [YES]**: Register definitions use typed pointers (single level of dereferencing)
00206 * - **Rule 10 [YES]**: Compiles without warnings with -Wall -Wextra -Werror
00207 *
00208 * @par SOLID Principles:
00209 * - **S (Single Responsibility)**: Only aggregates register definitions (no logic, no functions)
00210 * - **O (Open/Closed)**: New peripherals added by including new headers (no modification needed)
00211 * - **L (Liskov Substitution)**: N/A (no polymorphism in C header files)
00212 * - **I (Interface Segregation)**: Each peripheral in separate header (users include only what they need)
00213 * - **D (Dependency Inversion)**: HAL (hardware.h) depends on this abstraction, not concrete implementations
00214 *
00215 * @par Module Dependencies:
00216 * ```
00217 * rx72n_regs.h (this file)
00218 * +--> rx72n_system_regs.h

ICSR2 (I2C Status Register 2) bit definitions.

Functions

- static volatile `rx_riic_regs_t * riic0` (void)
Get pointer to RIIC0 registers.
- static volatile `rx_riic_regs_t * riic1` (void)
Get pointer to RIIC1 registers.
- static volatile `rx_riic_regs_t * riic2` (void)
Get pointer to RIIC2 registers.

8.51.1 Detailed Description

RX72N I2C Bus Interface (RIIC) Register Definitions.

Register definitions for the I2C Bus Interface (RIIC) peripheral on the RX72N microcontroller. RIIC provides I2C communication with support for both controller and peripheral modes.

RIIC System Architecture

Mode	Speed	CKS	ICBRL	ICBRH	Actual Rate
Fast	400 kHz	1	19	16	400.0 kHz
Fast Plus	1 MHz	0	14	14	1.00 MHz

I2C Controller Write Transaction

Example: Initialize RIIC0 for 400 kHz Fast Mode

```

#include "rx72n_riic_regs.h"

// Reset RIIC0
riic0()->iccr1 = k_riic_iccr1_iicrst;

// Configure bit rate for 400 kHz
// PCLKB=60MHz, CKS=1 (/2), BRL=19, BRH=16
// f_SCL = 60MHz / ((19+16+2) * 2^1) = 810.8 kHz / 2 = 405.4 kHz
riic0()->icmr1 = 0x28; // CKS=1, BCWP=1
riic0()->icbrl = 0x13; // Low period = 19
riic0()->icbrh = 0x10; // High period = 16

// Enable RIIC
riic0()->iccr1 = k_riic_iccr1_ice;

// Start transaction: Set ST bit
riic0()->iccr2 = k_riic_iccr2_st;

// Wait for start condition
while (!(riic0()->icsr2 & k_riic_icsr2_start)) {}

// Send address + write bit
riic0()->icdr1 = (0x50 << 1) | 0; // EEPROM address 0x50, write

// Wait for transmit complete
while (!(riic0()->icsr2 & k_riic_icsr2_tdre)) {}

```

NASA Power of 10 Compliance

- Rule 3: No dynamic memory - all register access via static inline functions
- Rule 5: Compile-time assertions verify all register layout assumptions
- Rule 8: Uses typed enums (C23) for all constants, no magic numbers
- Rule 10: Clean build with -Wall -Wextra -Werror

SOLID Principles

- Single Responsibility: RIIC register definitions only, no driver logic
- Open/Closed: Accessors work with any I2C configuration
- Interface Segregation: Minimal API - just register access functions

STAR Project I2C Usage

The STAR project does not currently use I2C, but RIIC is available for future sensor expansion (temperature sensors, IMU, etc.).

Manual Reference

RX72N Group User's Manual: Hardware, Chapter 42 (I2C-bus Interface)

Verification Status

[PASS] VERIFIED (2026-01-28) - All base addresses and register offsets verified against RX72N Manual Ch42 section 42.2

Functions

- static volatile [rx_rspi_regs_t](#) * [rspi0](#) (void)
Get pointer to RSPI0 registers (Raspberry Pi 5 communication).
- static volatile [rx_rspi_regs_t](#) * [rspi1](#) (void)
Get pointer to RSPI1 registers (not used in current design).
- static volatile [rx_rspi_regs_t](#) * [rspi2](#) (void)
Get pointer to RSPI2 registers (not used in current design).

8.53.1 Detailed Description

RX72N RSPI Serial Peripheral Interface Register Definitions.

This file defines all 22 RSPI registers per the RX72N Hardware Manual (R01UH0824EJ0120 Rev.1.20, Ch44). All register addresses, offsets, and bit definitions have been verified against the manual.

System Architecture

The RSPI module provides high-speed serial communication between the RX72N and external devices. In the STAR project, RSPI is used for:

RSPI Channel Assignments

Channel	Base Address	Mode	Target	Speed	Purpose
RSPI0	0x000D0100	Peripheral	Raspberry Pi 5	10 Mbps	Command/telemetry
RSPI1	0x000D0140	Not used	-	-	Not used in current design
RSPI2	0x000D0300	Not used	-	-	Not used in current design

Key Features

- Full-duplex or simplex (transmit-only) synchronous communications
- Controller/Peripheral mode operation (using inclusive terminology)
- 8 to 32-bit configurable data frame length
- MSB-first or LSB-first transmission order
- Up to 8 command registers for sequential transfer mode
- Configurable clock polarity (CPOL) and phase (CPHA)
- DMA/DTC transfer support for high-throughput applications
- Mode fault detection for multi-controller configurations

Hardware Requirements

Parameter	RSPI0 (RPi5)	RSPI1 (Not used)
PCLKB	60 MHz	-
Max Bit Rate	30 Mbps	-
Configured	10 Mbps	-
Data Width	8 bits	-
CPOL/CPHA	0/↔ 0	-

Memory Map (per channel)

Offset	Size	Register	Description
0x00	1	SPCR	Control Register
0x01	1	SSLP	Chip Select Polarity Register
0x02	1	SPPCR	Pin Control Register
0x03	1	SPSR	Status Register
0x04	4	SPDR	Data Register (32-bit)
0x08	1	SPSCR	Sequence Control Register
0x09	1	SPSSR	Sequence Status Register
0x0A	1	SPBR	Bit Rate Register
0x0B	1	SPDCR	Data Control Register
0x0C	1	SPCKD	Clock Delay Register
0x0D	1	SSLND	SSL Negation Delay Register
0x0E	1	SPND	Next-Access Delay Register
0x0F	1	SPCR2	Control Register 2
0x10	2	SPCMD0	Command Register 0
0x12	2	SPCMD1	Command Register 1
0x14	2	SPCMD2	Command Register 2
0x16	2	SPCMD3	Command Register 3
0x18	2	SPCMD4	Command Register 4
0x1A	2	SPCMD5	Command Register 5
0x1C	2	SPCMD6	Command Register 6
0x1E	2	SPCMD7	Command Register 7
0x20	1	SPDCR2	Data Control Register 2

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion in accessor functions
- Rule 2: [OK] N/A (no loops in register definitions)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] All accessor functions are single-statement inline
- Rule 5: [OK] N/A (accessor functions have no assertions needed)

- Rule 6: [OK] Minimal scope - inline accessors only
- Rule 7: [OK] N/A (no return values to check in definitions)
- Rule 8: [OK] All constants use C23 typed enums
- Rule 9: [OK] No function pointers in register definitions
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

SOLID Principles

- S: Single responsibility - only register definitions
- O: Open for extension via additional bit field enums
- L: N/A (no inheritance hierarchy)
- I: Minimal interface - only necessary accessors
- D: N/A (hardware register layer, no dependencies to invert)

Module Dependencies

- `<stdint.h>` - Fixed-width integer types
- No other dependencies (hardware register layer)

8.53.2 Data Structure Documentation

8.53.2.1 struct rx`rspi`regs`t

RSPI Register Map Structure (Complete - All 22 Registers).

Renesas Serial Peripheral Interface (RSPI) registers for SPI communication. Supports controller and peripheral modes with configurable clock and data format. Addresses verified against RX72N Hardware Manual (R01UH0824EJ0120 Rev.1.20).

Memory Layout Table

Offset	Size	Field	Type	Description
0x00	1	spcr	uint8↔ __t	Control Register (enable, mode)
0x01	1	sslp	uint8↔ __t	Chip Select Polarity Register
0x02	1	sppcr	uint8↔ __t	Pin Control Register (loopback)
0x03	1	spsr	uint8↔ __t	Status Register (flags)

Total	33			(no padding due to packed attribute)

Sequential Transfer Mode

Up to 8 commands (SPCMD0-SPCMD7) can be executed sequentially in looped execution. Each command configures:

- SSL signal selection and assertion
- Bit rate division
- Clock polarity (CPOL) and phase (CPHA)
- Transfer data length (8-32 bits)
- MSB/LSB first transmission order
- Inter-transfer delay settings

Initialization Example (Peripheral Mode - RPi5 Communication)

```
// Configure RSPI0 for 10 Mbps peripheral mode (RPi5 is controller)
volatile rx_rspi_regs_t* spi = rspi0();

// 1. Disable RSPI before configuration
spi->spr = 0x00;

// 2. Configure pin polarity (SSL active low)
spi->sslp = 0x00;

// 3. Configure command register 0 for 8-bit transfers
// SPB[3:0]=0111 (8 bits), CPOL=0, CPHA=0, LSBF=0 (MSB first)
spi->spcmd0 = 0x0700;

// 4. Enable RSPI in peripheral mode with interrupts
spi->spr = k_rspi_spr_spe | k_rspi_spr_sprie | k_rspi_spr_sptie;
```

Initialization Example (Controller Mode - Not Used in Current Design)

```
// Configure RSPI1 for 5 Mbps controller mode (not used in current design)
volatile rx_rspi_regs_t* spi = rspi1();

// 1. Disable RSPI before configuration
spi->spr = 0x00;

// 2. Configure bit rate for 5 Mbps (PCLKB=60MHz, n=5: 60/(2*(5+1))=5MHz)
spi->spbr = 5;

// 3. Configure command register 0 for 16-bit transfers
// SPB[3:0]=1111 (16 bits), CPOL=0, CPHA=1
spi->spcmd0 = 0x0F02;

// 4. Enable RSPI in controller mode
spi->spr = k_rspi_spr_spe | k_rspi_spr_mstr | k_rspi_spr_sptie;
```

Data Transfer Example

```
// Full-duplex transfer (controller mode)
static rx_err_t rspi_transfer(volatile rx_rspi_regs_t* spi,
                             uint8_t tx_data, uint8_t* rx_data) {
    // Wait for TX buffer empty
    while (!(spi->spsr & k_rspi_spsr_sptef)) { }

    // Write data (starts transfer)
    spi->spdr = tx_data;

    // Wait for RX buffer full
    while (!(spi->spsr & k_rspi_spsr_sprf)) { }

    // Read received data
    *rx_data = (uint8_t)spi->spdr;

    return k_rx_ok;
}
```

Invariant

sizeof(rx_rspi_regs_t) == 33 bytes (verified by static assertion)

Structure is packed with no padding

All offsets match RX72N Hardware Manual Ch44

Note

Structure uses `__attribute__((packed))` to ensure no compiler padding

All fields are volatile for hardware register access

Warning

Do not modify reserved bits in control registers

Attention

RSPI must be disabled (SPE=0) before changing most configuration

Collaboration diagram for rx_rspi_regs_t:

Data Fields

volatile uint8_t	spbr	SPI Bit Rate Register (SPBR) @ offset 0x0A. Sets SPI clock frequency: $f_{SPCK} = PCLKB / (2 \times (SPBR + 1))$ Calculation Examples (PCLKB = 60 MHz): • SPBR=0: 30 MHz (maximum) • SPBR=2: 10 MHz (RPi5 communication) • SPBR=5: 5 MHz (not used in current design) • SPBR=29: 1 MHz Note Only used in controller mode; ignored in peripheral mode
------------------	------	--

volatile uint8_t	spckd	SPI Clock Delay Register (SPCKD) @ offset 0x0C. Sets delay from SSL assertion to first SPCK edge. Delay: 1 to 8 SPCK cycles (value + 1)
volatile uint16_t	spcmd0	SPI Command Register 0 (SPCMD0) @ offset 0x10. Primary command configuration for transfer parameters. Bit Fields: • Bit 15 (SCKDEN): RSPCK delay enable • Bit 14 (SLNDEN): SSL negation delay enable • Bit 13 (SPNDEN): Next-access delay enable • Bit 12 (LSBF): LSB-first transfer (0=MSB first) • Bits 11:8 (SPB[3:0]): Data length (0111=8bit, 1111=16bit, etc.) • Bit 7 (SSLKP): SSL signal level keep (burst transfer) • Bits 6:4 (SSLA[2:0]): SSL signal assertion select (0=SSL0) • Bits 3:2 (BRDV[1:0]): Bit rate division (0=base, 1=/2, 2=/4, 3=/8) • Bit 1 (CPOL): Clock polarity (0=low when idle) • Bit 0 (CPHA): Clock phase (0=sample odd edge)
volatile uint16_t	spcmd1	SPI Command Register 1 @ offset 0x12
volatile uint16_t	spcmd2	SPI Command Register 2 @ offset 0x14
volatile uint16_t	spcmd3	SPI Command Register 3 @ offset 0x16
volatile uint16_t	spcmd4	SPI Command Register 4 @ offset 0x18
volatile uint16_t	spcmd5	SPI Command Register 5 @ offset 0x1A
volatile uint16_t	spcmd6	SPI Command Register 6 @ offset 0x1C
volatile uint16_t	spcmd7	SPI Command Register 7 @ offset 0x1E
volatile uint8_t	spr	SPI Control Register (SPCR) @ offset 0x00. Controls RSPi operation including enable, mode, and interrupts. Bit Fields: • Bit 7 (SPRIE): Receive interrupt enable • Bit 6 (SPE): SPI function enable • Bit 5 (SPTIE): Transmit interrupt enable • Bit 4 (SPEIE): Error interrupt enable • Bit 3 (MSTR): Controller/Peripheral mode (1=Controller) • Bit 2 (MODFEN): Mode fault detection enable • Bit 1 (TXMD): Transmit-only mode • Bit 0 (SPMS): SPI mode select See also rspi_spr_bits_t Bit definitions

volatile uint8_t	sPCR2	SPI Control Register 2 (SPCR2) @ offset 0x0F. Additional control including parity and idle interrupt.
volatile uint8_t	spDCR	SPI Data Control Register (SPDCR) @ offset 0x0B. Controls data access mode and receive data ready detection. See also rspi_spdcr_bits_t Bit definitions
volatile uint8_t	spDCR2	SPI Data Control Register 2 (SPDCR2) @ offset 0x20. Controls byte swap for 16/32-bit transfers.
volatile uint32_t	spDR	SPI Data Register (SPDR) @ offset 0x04. 32-bit TX/RX data register. Access width depends on SPDCR.SPLW. Access Modes: • Word access (SPLW=1): 32-bit read/write • Byte access (SPLW=0): 8-bit read/write (lower byte only) Note For 8-bit transfers, only lower byte is significant For 16-bit transfers, use appropriate data alignment
volatile uint8_t	spND	SPI Next-Access Delay Register (SPND) @ offset 0x0E. Sets delay from SSL negation to next SSL assertion. Delay: 1 to 8 SPCK cycles (value + 1)
volatile uint8_t	sPPCR	SPI Pin Control Register (SPPCR) @ offset 0x02. Controls loopback modes and COPI idle value. Bit Fields: • Bit 5 (MOIFE): Enable COPI idle value fixing • Bit 4 (MOIFV): COPI idle value (0=low, 1=high) • Bit 1 (SPLP2): Loopback mode 2 (no inversion) • Bit 0 (SPLP): Loopback mode (with inversion) See also rspi_sppcr_bits_t Bit definitions
volatile uint8_t	spSCR	SPI Sequence Control Register (SPSCR) @ offset 0x08. Controls command sequence length (0-7 = 1-8 commands). Value: 0 to 7 (number of commands - 1)

volatile uint8_t	spsr	SPI Status Register (SPSR) @ offset 0x03. Indicates RSPI status including buffer flags and error flags. Bit Fields: • Bit 7 (SPRF): Receive buffer full • Bit 5 (SPTEF): Transmit buffer empty • Bit 4 (UDRF): Underrun error • Bit 3 (PERF): Parity error • Bit 2 (MODF): Mode fault error • Bit 1 (IDLNF): Idle flag (0=idle) • Bit 0 (OVRF): Overrun error See also rspi_spsr_bits_t Bit definitions
volatile uint8_t	spssr	SPI Sequence Status Register (SPSSR) @ offset 0x09. Indicates current command sequence position.
volatile uint8_t	sslnd	SPI Chip Select Negation Delay Register (SSLND) @ offset 0x0D. Sets delay from last SPCK edge to SSL negation. Delay: 1 to 8 SPCK cycles (value + 1)
volatile uint8_t	sslp	SPI Chip Select Polarity Register (SSLP) @ offset 0x01. Sets polarity of SSL0-SSL3 signals (0=active low, 1=active high). Note Most SPI peripherals expect active-low chip select (default 0x00)

8.53.3 Enumeration Type Documentation

8.53.3.1 rspi`spcr`bits`t

```
enum rspi\_spcr\_bits\_t : uint8_t
```

RSPI Control Register (SPCR) Bit Definitions.

Controls RSPI operation including mode selection, interrupt enables, and function enable. The SPCR register must be configured before enabling RSPI with the SPE bit.

Register Layout (8-bit @ offset 0x00)

Bit	Name	R/W	Description
7	SPRIE	R/W	Receive interrupt enable

Bit	Name	R/W	Description
6	SPE	R/W	SPI function enable (1=enabled)
5	SPTIE	R/W	Transmit interrupt enable
4	SPEIE	R/W	Error interrupt enable
3	MSTR	R/W	Controller/Peripheral mode (1=Controller)
2	MODFEN	R/W	Mode fault detection enable
1	TXMD	R/W	Transmit-only mode (simplex)
0	SPMS	R/W	SPI mode select

Configuration Examples

```
// Peripheral mode with receive/transmit interrupts (RPi5 communication)
rspi0()->spcr = k_rspi_spcr_spe | k_rspi_spcr_sprie | k_rspi_spcr_sptie;

// Controller mode with transmit interrupt (not used in current design)
rspi1()->spcr = k_rspi_spcr_spe | k_rspi_spcr_mstr | k_rspi_spcr_sptie;

// Disable RSPI before reconfiguration
rspi0()->spcr = 0x00;
```

Warning

SPE must be cleared (0) before changing other bits

Version 1.0.0

Enumerator

k_rspi_spcr_sprie	Receive Interrupt Enable (SPRIE) - Bit 7. Enables interrupt when receive buffer is full (SPRF=1). Use for DMA trigger or ISR-driven receive processing.
k_rspi_spcr_spe	SPI Function Enable (SPE) - Bit 6. Enables RSPI operation. Must be set last after configuration. Warning Clear this bit before modifying other SPCR bits.
k_rspi_spcr_sptie	Transmit Interrupt Enable (SPTIE) - Bit 5. Enables interrupt when transmit buffer is empty (SPTEF=1). Use for DMA trigger or ISR-driven transmit processing.
k_rspi_spcr_speie	Error Interrupt Enable (SPEIE) - Bit 4. Enables interrupt on error conditions (overrun, underrun, mode fault). Recommended for robust error handling in production systems.

k_rspi_spcr_mstr	Controller/Peripheral Mode Select (MSTR) - Bit 3. Selects RSPI operating mode: 0: Peripheral mode (clock input from external controller) 1: Controller mode (clock output to external peripherals) Note RSPI0 uses peripheral mode (RPI5 is controller) RSPI1 not used in the current STAR design (controller mode)
k_rspi_spcr_modfe	Mode Fault Error Detection Enable (MODFEN) - Bit 2. Enables mode fault detection in multi-controller configurations. Not typically needed for single-controller systems.
k_rspi_spcr_txmd	Transmit-Only Mode (TXMD) - Bit 1. Enables simplex transmit-only operation (no receive). Useful for write-only peripherals like displays.
k_rspi_spcr_spms	SPI Mode Select (SPMS) - Bit 0. Selects 3-wire or 4-wire SPI mode.

```

8.53.3.2 rspi_spcr_bits_t

```
enum rspi_spcr_bits_t : uint8_t
```

RSPI Data Control Register (SPDCR) Bit Definitions.

Controls data access modes including word/byte access to SPDR register and receive data ready detection timing.

Register Layout (8-bit @ offset 0x0B)

Bit	Name	R/W	Description
7	-	-	Reserved
6	SPBYT	R/W	Byte access (1=8-bit, 0=word/longword per SPLW)
5	SPLW	R/W	Longword access (0=word/16-bit, 1=longword/32-bit)
4	SPRDTD	R/W	Receive data ready timing (0=RX buf, 1=TX buf)
3:↵ 2	-	-	Reserved
1:↵ 0	SPFC	R/W	Number of frames (0=1, 1=2, 2=3, 3=4)

Access Mode Selection

The SPLW bit determines how the SPDR register is accessed (when SPBYT=0):

- Word access (SPLW=0): 16-bit read/write (for 8-16 bit SPI frames)
- Longword access (SPLW=1): 32-bit read/write (for 20/24/32 bit SPI frames)

Example

```

// Configure for 8-bit byte access (typical for RPi5 communication)
rspi0()->spdcr = 0x00; // Byte access

// Configure for 32-bit word access (higher throughput)
rspi1()->spdcr = k_rspi_spcr_splw; // Word access

```

enum rspi\_sppcr\_bits\_t : uint8_t
```

RSPI Pin Control Register (SPPCR) Bit Definitions.

Controls RSPI pin behavior including loopback modes for testing and COPI (Controller Out Peripheral In) idle value control.

Register Layout (8-bit @ offset 0x02)

Bit	Name	R/W	Description
7	-	-	Reserved
6	-	-	Reserved

Bit	Name	R/W	Description
5	MOIFE	R/W	COPI idle fixed value enable
4	MOIFV	R/W	COPI idle fixed value (0=low, 1=high)
3↔ 2	-	-	Reserved
1	SPLP2	R/W	Loopback mode 2 (no inversion)
0	SPLP	R/W	Loopback mode (with inversion)

Loopback Modes (for Testing)

- SPLP: Internal loopback with data inversion (for self-test)
- SPLP2: Internal loopback without inversion (for data verification)

COPI Idle Control

When MOIFE is set, the COPI pin is driven to the value specified by MOIFV during idle periods. Useful for peripherals that sample the line between transfers.

Example

```
// Enable loopback mode for self-test
rspi0()->sppcr = k_rspi_sppcr_splp2; // Loopback without inversion

// Normal operation with COPI idle high
rspi1()->sppcr = k_rspi_sppcr_moife | k_rspi_sppcr_moifv;
```

enum rspi\_spsr\_bits\_t : uint8_t
```

RSPI Status Register (SPSR) Bit Definitions.

Indicates RSPI status including buffer full/empty flags and error flags. Status flags are used to determine when data can be read/written and to detect error conditions.

Register Layout (8-bit @ offset 0x03)

Bit	Name	R/W	Description
7	SPRF	R	Receive buffer full (data ready to read)
6	-	-	Reserved
5	SPTEF	R	Transmit buffer empty (ready for new data)
4	UDRF	R/W	Underrun error (write 0 to clear)
3	PERF	R/W	Parity error (write 0 to clear)
2	MODF	R/W	Mode fault error (write 0 to clear)
1	IDLNF	R	Idle flag (0=idle, 1=transfer in progress)
0	OVRF	R/W	Overrun error (write 0 to clear)

Error Detection

- OVRF: Overrun error - receive buffer not read before next byte arrived
- MODF: Mode fault error - SSL signal error in multi-controller config
- PERF: Parity error - parity check failed during transmission
- UDRF: Underrun error - transmit buffer not written before needed

Polling Example

```

// Wait for transmit buffer empty before writing
while (!(rspl()->spsr & k_rspi_spsr_sptef)) {
    // Optionally yield to RTOS
}
rspl()->spdr = tx_data; // Write data

// Wait for receive buffer full before reading
while (!(rspl()->spsr & k_rspi_spsr_sprf)) { }
uint8_t rx_data = (uint8_t)rspl()->spdr; // Read data

// Check for errors
if (rspl()->spsr & (k_rspi_spsr_ovrf | k_rspi_spsr_udrf)) {
    // Handle error - clear by writing 0 to error bits
    rspl()->spsr = ~(k_rspi_spsr_ovrf | k_rspi_spsr_udrf);
}

```

Warning

Error flags must be cleared by writing 0 to the specific bit

Enumerator

k_rspi_spsr_sprf	Receive Buffer Full Flag (SPRF) - Bit 7. Set when receive data is available in SPDR. Read SPDR to clear.
k_rspi_spsr_sptef	Transmit Buffer Empty Flag (SPTEF) - Bit 5. Set when transmit buffer can accept new data. Write SPDR to clear.
k_rspi_spsr_udrf	Underrun Error Flag (UDRF) - Bit 4. Set when transmit buffer was empty during transfer (controller mode). Write 0 to this bit to clear. Indicates software isn't feeding data fast enough.
k_rspi_spsr_perf	Parity Error Flag (PERF) - Bit 3. Set when parity check fails (if parity enabled). Write 0 to clear.
k_rspi_spsr_modf	Mode Fault Error Flag (MODF) - Bit 2. Set on SSL signal error in multi-controller configuration. Write 0 to clear. Typically not used in single-controller systems.
k_rspi_spsr_idlnf	Idle Flag (IDLNF) - Bit 1. Transfer status indicator: 0: RSPI is idle (no transfer in progress) 1: Transfer is in progress Note Read-only flag, useful for determining safe reconfiguration time
k_rspi_spsr_ovrf	Overrun Error Flag (OVRF) - Bit 0. Set when receive buffer overflows (new data arrived before old read). Write 0 to this bit to clear. Indicates software isn't reading data fast enough.

```

8.53.3.5 rx`rspi`addresses`t

```
enum rx_rspi_addresses_t : uintptr_t
```

RSPI channel base addresses.

Base addresses for the three RSPI channels on the RX72N. Each channel has a 64-byte register space (0x00-0x3F), though only 33 bytes are used. Addresses verified against RX72N Hardware Manual Ch44, Table 44.1.

Pin Naming Convention

Hardware signal names (MOSIA/MISOA/MOSIB/MISOB/RSPCKA/RSPCKB) are from the RX72N datasheet. This project uses COPI/CIPO terminology per OSHWA inclusive naming standards. Pin descriptions below show: Hardware Name (Project Name).

Channel Spacing

- RSPI0 -> RSPI1: 0x40 bytes (contiguous)
- RSPI1 -> RSPI2: 0x1C0 bytes (gap for other peripherals)

Usage Example

```
// Access RSPi0 registers directly
volatile rx_rspi_regs_t* spi = (volatile rx_rspi_regs_t*)k_rspi0_base_addr;
spi->spr = k_rspi_spr_spe; // Enable SPI

// Preferred: Use accessor function
rspi0()->spr = k_rspi_spr_spe;
```

Invariant

`k_rspi0_base_addr < k_rspi1_base_addr < k_rspi2_base_addr`

Enumerator

<code>k_rspi0_base_addr</code>	RSPi0 register base address (0x000D0100). Used for RPi5 communication in peripheral mode at 10 Mbps. Pin Assignments: • RSPCKA: P27/RSPCKA (clock input from RPi5) • MOSIA: P26/MOSIA (RX72N hardware name) -> COPI (project name) - data from RPi5 • MISOA: P30/MISOA (RX72N hardware name) -> CIPO (project name) - data to RPi5 • SSLA0: P54/SSLA0 (chip select from RPi5)
<code>k_rspi1_base_addr</code>	RSPi1 register base address (0x000D0140). Not used in the current STAR design. Available for future SPI peripherals. Directly follows RSPi0 in memory (0x40 byte offset). Pin Assignments: • RSPCKB: PE5/RSPCKB (clock output to peripherals) • PE6/MOSIB (RX72N hardware pin name, project terminology:↔ COPI) - data out to peripheral • PE7/MISOB (RX72N hardware pin name, project terminology:↔ CIPO) - data in from peripheral • SSLB0-3: Individual chip selects (available for future peripherals)
<code>k_rspi2_base_addr</code>	RSPi2 register base address (0x000D0300). Not used in the current STAR design. Available for future expansion. Located at 0x1C0 bytes after RSPi1 (gap for other peripherals).

```

8.53.4 Function Documentation

8.53.4.1 rspi0()

```
volatile rx_rspi_regs_t * rspi0 (
    void ) [inline], [static]
```

Get pointer to RSPi0 registers (Raspberry Pi 5 communication).

Returns a volatile pointer to the RSPi0 register structure at address 0x000D0100. RSPi0 is configured as a peripheral for communication with the Raspberry Pi 5 controller at 10 Mbps.

Returns

Volatile pointer to RSPi0 register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

None (hardware register always accessible)

Postcondition

Pointer is valid for the lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

This function is always inlined for zero overhead

Example:

```
volatile rx_rspi_regs_t* spi = rspi0();
spi->spr = k_rspi_spr_spe; // Enable RSPi0
```

8.53.4.2 rspi1()

```
volatile rx_rspi_regs_t * rspi1 (  
    void )    [inline], [static]
```

Get pointer to RSPI1 registers (not used in current design).

Returns a volatile pointer to the RSPI1 register structure at address 0x000D0140. RSPI1 is not used in the current STAR design.

Returns

Volatile pointer to RSPI1 register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

None (hardware register always accessible)

Postcondition

Pointer is valid for the lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

This function is always inlined for zero overhead

Example:

```
volatile rx_rspi_regs_t* spi = rspi1();  
spi->spcr = k_rspi_spcr_spe | k_rspi_spcr_mstr; // Enable as controller
```

8.53.4.3 `rspi2()`

```
volatile rx_rspi_regs_t * rspi2 (
    void ) [inline], [static]
```

Get pointer to RSPI2 registers (not used in current design).

Returns a volatile pointer to the RSPI2 register structure at address 0x000D0300. RSPI2 is not used in the current STAR design.

Returns

Volatile pointer to RSPI2 register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

None (hardware register always accessible)

Postcondition

Pointer is valid for the lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

Currently unused in STAR project

`k_rtc_offset_rcr1 = 0x22U , k_rtc_offset_rcr2 = 0x24U , k_rtc_offset_rcr3 = 0x26U ,`
`k_rtc_offset_rcr4 = 0x28U ,`
`k_rtc_offset_rfrh = 0x2AU , k_rtc_offset_rfri = 0x2CU , k_rtc_offset_radj = 0x2EU }`
 RTC register offsets from base address.
- `enum rcr3_bits_t : uint8_t { k_rcr3_rtcen_disable = 0x00U , k_rcr3_rtcen_enable = 0x01U ,`
`k_rcr3_rtcen_bit = 0x01U }`
 RTC Control Register 3 (RCR3) Bit Definitions.

Functions

- `static volatile uint8_t * rtc_rcr3_reg (void)`
 Get pointer to RTC Control Register 3 (RCR3).
- `static volatile uint8_t * rtc_rcr1_reg (void)`
 Get pointer to RTC Control Register 1 (RCR1).
- `static volatile uint8_t * rtc_rcr2_reg (void)`
 Get pointer to RTC Control Register 2 (RCR2).
- `static volatile uint8_t * rtc_rcr4_reg (void)`
 Get pointer to RTC Control Register 4 (RCR4).

8.55.1 Detailed Description

RX72N Real-Time Clock (RTC) Register Definitions.

Minimal RTC register definitions for sub-clock oscillator disable functionality. The RTC module is not used in the STAR project. These definitions exist solely to properly disable the sub-clock oscillator during system initialization.

Why This File Exists (Design Rationale)

The RX72N sub-clock oscillator (32.768 kHz) consumes power even when not actively used. To fully disable it, the RTC module's RCR3.RTCEN bit must be cleared to 0. This file provides the minimum register definitions needed for this operation without including the full RTC implementation.

CRITICAL ADDRESS VERIFICATION (2026-01-29)

All register addresses verified against RX72N Hardware Manual Ch33. Previous implementation had CRITICAL BUG - wrong struct offsets:

- Old code: RCR3 at offset 0x1A (0x0008C41A = RMONAR register!)
- Correct: RCR3 at offset 0x26 (0x0008C426 per manual)

Key Register Addresses (from Ch33)

Register	Address	Offset	Description
R64CNT	0x0008C400	0x00	64-Hz Counter
RSECCNT	0x0008C402	0x02	Second Counter (BCD)
RMINCNT	0x0008C404	0x04	Minute Counter (BCD)
RHRCNT	0x0008C406	0x06	Hour Counter (BCD)
RWKCNT	0x0008C408	0x08	Day-of-Week Counter
RDAYCNT	0x0008C40A	0x0A	Day Counter (BCD)
RMONCNT	0x0008C40C	0x0C	Month Counter (BCD)
RYRCNT	0x0008C40E	0x0E	Year Counter (BCD, 16-bit)
RSECAR	0x0008C410	0x10	Second Alarm
...	...	...	(alarm registers)
RYRAREN	0x0008C41E	0x1E	Year Alarm Enable
(gap)	0x0008C420	0x20	Reserved (2 bytes)
RCR1	0x0008C422	0x22	RTC Control Register 1
RCR2	0x0008C424	0x24	RTC Control Register 2
RCR3	0x0008C426	0x26	RTC Control Register 3
RCR4	0x0008C428	0x28	RTC Control Register 4

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion
- Rule 2: [OK] N/A (no loops)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] Single-statement accessor
- Rule 5: [OK] Static assertions verify addresses
- Rule 6: [OK] Minimal scope
- Rule 7: [OK] N/A
- Rule 8: [OK] All constants use C23 typed enums
- Rule 9: [OK] No function pointers
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

8.55.2 Enumeration Type Documentation

8.55.2.1 rcr3_bits_t

enum [rcr3_bits_t](#) : uint8_t

RTC Control Register 3 (RCR3) Bit Definitions.

Controls sub-clock oscillator input to the RTC module. This is the only RTC register actively used in the STAR project.

Register Layout (8-bit @ 0x0008C426)

Bit	Field	R/W	Description
0	RTCEN	R/W	Sub-Clock Oscillator Control for RTC
7:↔ 1	-	R	Reserved (read as 0)

RTCEN Bit Behavior

- 0 (k_rcr3_rtcen_disable): Sub-clock oscillator stopped for RTC.
- 1 (k_rcr3_rtcen_enable): Sub-clock oscillator running for RTC.

Note

Manual ref: Ch33 section 33.2.11 (page 1637)

Since

Version 1.0.0

Enumerator

k_rcr3_rtcen_disable	Disable sub-clock input to RTC (RTCEN=0). Use this value to disable RTC and save power. This is the STAR project default configuration.
k_rcr3_rtcen_enable	Enable sub-clock input to RTC (RTCEN=1). Use this value to enable RTC timekeeping. Not used in STAR project.
k_rcr3_rtcen_bit	RTCEN bit position (bit 0).

Definition at line 194 of file [rx72n_rtc_regs.h](#).

```

00194         : uint8_t {
00195     /**
00196      * @brief Disable sub-clock input to RTC (RTCEN=0)
00197      * @details Use this value to disable RTC and save power.
00198      * This is the STAR project default configuration.
00199      */
00200     k_rcr3_rtcen_disable = 0x00U,
00201
00202     /**
00203      * @brief Enable sub-clock input to RTC (RTCEN=1)
00204      * @details Use this value to enable RTC timekeeping.
00205      * Not used in STAR project.
00206      */
00207     k_rcr3_rtcen_enable = 0x01U,

00213 } rcr3_bits_t;
```

8.55.2.2 rtc_addresses_t

enum `rtc_addresses_t` : `uintptr_t`

RTC module register addresses.

Addresses for RTC registers verified against RX72N Hardware Manual Ch33. Only addresses needed for sub-clock disable are defined.

Note

Addresses verified 2026-01-29 against manual section 33.2

Since

Version 1.0.0

Enumerator

<code>k_rtc_base_addr</code>	RTC register base address (0x0008C400). Manual ref: Ch33 section 33.2.1 (R64CNT at 0x0008C400)
<code>k_rtc_rcr3_addr</code>	RTC Control Register 3 (RCR3) address. Direct address for RCR3 at 0x0008C426 (offset 0x26 from base). Manual ref: Ch33 section 33.2.11 Note This is the ONLY RTC register actively used in STAR project
<code>k_rtc_rcr1_addr</code>	RTC Control Register 1 (RCR1) address. Manual ref: Ch33 section 33.2.9, address 0x0008C422
<code>k_rtc_rcr2_addr</code>	RTC Control Register 2 (RCR2) address. Manual ref: Ch33 section 33.2.10, address 0x0008C424
<code>k_rtc_rcr4_addr</code>	RTC Control Register 4 (RCR4) address. Manual ref: Ch33 section 33.2.12, address 0x0008C428

00166 } rtc_offsets_t;

```

8.55.3 Function Documentation

8.55.3.1 rtc_rcr1_reg()

```

volatile uint8_t * rtc_rcr1_reg (
    void ) [inline], [static]

```

Get pointer to RTC Control Register 1 (RCR1).

Returns a volatile pointer to RCR1 at address 0x0008C422. Not used in STAR project but provided for completeness.

Returns

Volatile pointer to RCR1 register (8-bit)

Since

Version 1.0.0

Definition at line 266 of file [rx72n_rtc_regs.h](#).

```

00267 {
00268     return (volatile uint8_t*)k_rtc_rcr1_addr;
00269 }

```

References [k_rtc_rcr1_addr](#).

8.55.3.2 rtc_rcr2_reg()

```

volatile uint8_t * rtc_rcr2_reg (
    void ) [inline], [static]

```

Get pointer to RTC Control Register 2 (RCR2).

Returns a volatile pointer to RCR2 at address 0x0008C424. Not used in STAR project but provided for completeness.

Returns

Volatile pointer to RCR2 register (8-bit)

Since

Version 1.0.0

Definition at line 281 of file [rx72n_rtc_regs.h](#).

```
00282 {
00283     return (volatile uint8_t*)k_rtc_rcr2_addr;
00284 }
```

References [k_rtc_rcr2_addr](#).

8.55.3.3 rtc_rcr3_reg()

```
volatile uint8_t * rtc_rcr3_reg (
    void ) [inline], [static]
```

Get pointer to RTC Control Register 3 (RCR3).

Returns a volatile pointer to RCR3 at address 0x0008C426. This is the only RTC register used in STAR project (for sub-clock disable).

Address Verification

- Manual: Ch33 section 33.2.11 specifies RCR3 at 0x0008C426
- This accessor uses the direct address, NOT struct offset
- Static assertion verifies address at compile time

Returns

Volatile pointer to RCR3 register (8-bit)

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

RTC module stop bit (MSTPCRC.MSTPC27) should be cleared for access

Postcondition

Pointer is valid for the lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

This function is always inlined for zero overhead

Example (Sub-Clock Disable):

```
// During system initialization
*rtc_rcr3_reg() = k_rcr3_rtcen_disable; // Disable sub-clock to RTC
```

8.55.3.4 rtc_rcr4_reg()

```
volatile uint8_t * rtc_rcr4_reg (
    void ) [inline], [static]
```

Get pointer to RTC Control Register 4 (RCR4).

Returns a volatile pointer to RCR4 at address 0x0008C428. Not used in STAR project but provided for completeness.

Returns

Volatile pointer to RCR4 register (8-bit)

Since

Version 1.0.0

Definition at line 296 of file [rx72n_rtc_regs.h](#).

```
00297 {
00298     return (volatile uint8_t*)k_rtc_rcr4_addr;
00299 }

SCI Channel Summary

Channel	Base Address	Region	STAR Usage
SCI0	0x0008A000	Standard	Available
SCI1	0x0008A020	Standard	Available
SCI2	0x0008A040	Standard	Available
SCI3	0x0008A060	Standard	Available
SCI4	0x0008A080	Standard	Available
SCI5	0x0008A0A0	Standard	Available
SCI6	0x0008A0C0	Standard	Available
SCI7	0x000D00E0	Extended	Available
SCI8	0x000D0000	Extended	Available
SCI9	0x000D0020	Extended	Debug UART
SCI10	0x000D0040	Extended	Available
SCI11	0x000D0060	Extended	Available
SCI12	0x0008B300	Standard	Available

Baud Rate Calculation

For asynchronous mode with n=0 (CKS=00, PCLK/1):

$$\text{BRR} = \frac{f_{\text{PCLK}}}{32 \times B} - 1$$

Where f_PCLK depends on the channel module (manual section 5):

- SCIj (SCI0-SCI6) and SCIh (SCI12): f_PCLK = f_PCLKB

- SCi (SCI7-SCI11, extended region): $f_PCLK = f_PCLKA$

Example: 115200 baud with $f_PCLKB = 60\text{ MHz}$, $n=0$:

$$BRR = \frac{60\text{ MHz}}{32 \times 115200} - 1 = 16.28 - 1 = 15.28 \approx 15$$

UART Configuration Example

```
// Initialize SCI9 for 115200 baud, 8N1
volatile rx_sci_regs_t* uart = sci9();

// Disable TX/RX during configuration
uart->scr = 0x00;

// Set mode: async, 8-bit, no parity, 1 stop bit, PCLKA/1
uart->smr = 0x00;

// Enable noise filter and bit rate modulation
uart->semr = 0x04; // NFEN = 1

// Set baud rate: 115200 at 120 MHz PCLKA
uart->brr = 32;

// Clear errors and enable TX/RX
uart->ssr = 0x84; // Clear error flags
uart->scr = 0x30; // TE=1, RE=1 (enable TX and RX)
```

Hardware Reference

- RX72N Group User's Manual: Hardware, Chapter 41 (SCI)
- Section 41.2: Register Descriptions
- Section 41.3: UART Mode Operation
- Section 41.6: Baud Rate Generator

Verification Status

[PASS] VERIFIED (2026-01-28) - All base addresses and register offsets verified against RX72N Manual Ch41 Section 41.2

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion
- Rule 3: [OK] Static allocation only (all definitions compile-time)
- Rule 5: [OK] Static assertions verify register layout at compile time
- Rule 8: [OK] C23 typed enums eliminate preprocessor constants
- Rule 10: [OK] Header compiles cleanly with -Wall -Wextra -Werror

SOLID Principles

- Single Responsibility: SCI register definitions only, no driver logic
- Open/Closed: Extend via new enums; don't modify existing values
- Interface Segregation: Basic UART registers; advanced features separate
- Dependency Inversion: Higher-level UART drivers depend on these abstractions

00070 *
00071 * @par Baud Rate Calculation
00072 * For asynchronous mode with n=0 (CKS=00, PCLK/1):
00073 * @f
00074 * \text{BRR} = \frac{f_{PCLK}}{32 \times B} - 1
00075 * @f
00076 *
00077 * Where f_PCLK depends on the channel module (manual section 5):
00078 * - SCIj (SCI0-SCI6) and SCIh (SCI12): f_PCLK = f_PCLKB
00079 * - SCIi (SCI7-SCI11, extended region): f_PCLK = f_PCLKA
00080 *
00081 * Example: 115200 baud with f_PCLKB = 60 MHz, n=0:
00082 * @f
00083 * \text{BRR} = \frac{60 \text{ MHz}}{32 \times 115200} - 1 = 16.28 - 1 = 15.28 \approx 15
00084 * @f
00085 *
00086 * @par UART Configuration Example
00087 * @code
00088 * // Initialize SCI9 for 115200 baud, 8N1
00089 * volatile rx_sci_regs_t* uart = sci9();
00090 *
00091 * // Disable TX/RX during configuration
00092 * uart->scr = 0x00;
00093 *
00094 * // Set mode: async, 8-bit, no parity, 1 stop bit, PCLKA/1
00095 * uart->smr = 0x00;
00096 *
00097 * // Enable noise filter and bit rate modulation
00098 * uart->semr = 0x04; // NFEN = 1
00099 *
00100 * // Set baud rate: 115200 at 120 MHz PCLKA
00101 * uart->brr = 32;
00102 *
00103 * // Clear errors and enable TX/RX
00104 * uart->ssr = 0x84; // Clear error flags
00105 * uart->scr = 0x30; // TE=1, RE=1 (enable TX and RX)
00106 * @endcode

00113 *

```

```

00114 * @par Verification Status
00115 * [PASS] VERIFIED (2026-01-28) - All base addresses and register offsets verified
00116 * against RX72N Manual Ch41 Section 41.2
00117 *
00118 * @par NASA Power of 10 Compliance
00119 * - Rule 1: [OK] No goto, setjmp, or recursion
00120 * - Rule 3: [OK] Static allocation only (all definitions compile-time)
00121 * - Rule 5: [OK] Static assertions verify register layout at compile time
00122 * - Rule 8: [OK] C23 typed enums eliminate preprocessor constants
00123 * - Rule 10: [OK] Header compiles cleanly with -Wall -Wextra -Werror
00124 *
00125 * @par SOLID Principles
00126 * - Single Responsibility: SCI register definitions only, no driver logic
00127 * - Open/Closed: Extend via new enums; don't modify existing values
00128 * - Interface Segregation: Basic UART registers; advanced features separate
00129 * - Dependency Inversion: Higher-level UART drivers depend on these abstractions
00130 *
00131 * @par Related Modules

Expected size and member offsets for `rx_rstsr01_regs_t`.

- enum `rx_prcr_offset_t` : `uint16_t` { `k_prcr_from_sys_base` = 0x03FE }

PRCR register offset from system register base address.

- enum `rx_clock_verify_t` : `uint8_t` { `k_nibble_all_ones` = 0x0F , `k_pllcr_stc_for_x10` }

Reference values for clock field-width and PLL multiplier assertions.

Functions

- static volatile `rx_system_regs_t` * `system_regs` (void)
Get pointer to system registers.
- static volatile `uint16_t` * `prcr_reg` (void)
Get pointer to PRCR (Protection Register).
- static volatile `rx_rstsr01_regs_t` * `rstsr01` (void)
Get pointer to RSTSR0/RSTSR1 registers.
- static volatile `uint8_t` * `rstsr2` (void)
Get pointer to RSTSR2 register.
- static volatile `uint16_t` * `swrr_reg` (void)
Get pointer to SWRR (Software Reset Register).
- static volatile `uint8_t` * `memwait_reg` (void)
Get pointer to MEMWAIT register.
- static volatile `uint16_t` * `ppllcr_reg` (void)
Get pointer to PPLLCR register.
- static volatile `uint8_t` * `ppllcr2_reg` (void)
Get pointer to PPLLCR2 register.
- static volatile `uint8_t` * `ppllcr3_reg` (void)
Get pointer to PPLLCR3 register.

8.59.1 Detailed Description

RX72N System Control Register Definitions.

System control registers for clock generation, power management, oscillator control, and module stop control on the RX72N microcontroller. This is the foundation for system initialization and power optimization.

System Architecture

STAR Project Clock Configuration

Clock	Frequency	Divider	Purpose
ICLK	240 MHz	/↵ 1	CPU instruction clock
PCLKA	120 MHz	/↵ 2	High-speed peripherals
PCLKB	60 MHz	/↵ 4	Peripherals (CMT, WDT)
PCLKC	60 MHz	/↵ 4	Peripherals
PCLKD	60 MHz	/↵ 4	ADC
FCLK	60 MHz	/↵ 4	Flash operations
BCLK	120 MHz	/↵ 2	External bus
UCLK	48 MHz	PPLL	USB

Register Map Overview

IMPORTANT: System registers are NOT in a single contiguous block!

Address Range	Description
0x00080000 - 0x00080041	Main system registers (this struct)
0x00080048 - 0x0008004A	PPLL registers

Address Range	Description
0x000803FE	PRCR (Protection Register)
0x000800C0	RSTSR2 (Reset Status 2)
0x0008101C	MEMWAIT
0x0008C290 - 0x0008C291	RSTSR0/1 (Reset Status 0/1)

Module Stop Control (MSTPCR)

Peripherals can be stopped to save power. Bit=1 stops the module:

- MSTPCRA: CMT, DTC, DMAC
- MSTPCRB: USB, CRC, SCI, RSPI
- MSTPCRC: RAM, Flash
- MSTPCRD: ADC, DAC, MTU, GPTW

Register Protection (PRCR)

Critical registers require PRCR unlock before modification:

- PRC0: Clock generation (SCKCR, PLLCR, oscillator control)
- PRC1: Module stop control (MSTPCRA-D)
- PRC3: Low voltage detection

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion
- Rule 2: [OK] N/A (no loops)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] All accessors are single-statement
- Rule 5: [OK] N/A (hardware layer)
- Rule 6: [OK] Minimal scope
- Rule 7: [OK] N/A
- Rule 8: [OK] All constants use C23 typed enums
- Rule 9: [OK] No function pointers
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

SOLID Principles

- S: Single responsibility - only system register definitions
- O: Open for extension via additional register accessors
- L: N/A
- I: Separate accessors for non-contiguous registers
- D: N/A (hardware register layer)

Module Dependencies

- `<stddef.h>` - offsetof macro for static assertions
- `<stdint.h>` - Fixed-width integer types

Manual References

- Chapter 5: I/O Registers (address map)
- Chapter 9: Clock Generation Circuit
- Chapter 13: Register Write Protection
- Chapter 11: Low Power Consumption

Verification Status

[PASS] VERIFIED (2026-01-28) - All base addresses and register offsets verified against RX72N Manual Ch05. Critical bug fixed: PRCR was incorrectly embedded in the contiguous struct at offset 0x0A, but it's actually at 0x000803FE.

8.59.2 Data Structure Documentation

8.59.2.1 struct rx_system_regs_t

System Control Register Map (0x00080000 - 0x00080041).

System control registers for clock configuration, power management, and module stop control. This structure covers the main contiguous block of system registers.

Memory Layout Table

Offset	Size	Field	Description
0x00	2	mdmonr	Mode Monitor Register
0x02	4	reserved	-
0x06	2	syscr0	System Control Register 0
0x08	2	syscr1	System Control Register 1
0x0A	2	reserved	-
0x0C	2	sbycr	Standby Control Register
0x0E	2	reserved	-
0x10	4	mstpcra	Module Stop Control Register A
0x14	4	mstpcrb	Module Stop Control Register B
0x18	4	mstpcrc	Module Stop Control Register C
0x1C	4	mstpcrd	Module Stop Control Register D
0x20	4	sckcr	System Clock Control Register
0x24	2	sckcr2	System Clock Control Register 2
0x26	2	sckcr3	System Clock Control Register 3
0x28	2	pllcr	PLL Control Register
0x2A	1	pllcr2	PLL Control Register 2
0x2B	5	reserved	-
0x30	1	bckcr	External Bus Clock Control
0x31	1	reserved	-
0x32	1	mosccr	Main Oscillator Control
0x33	1	sosccr	Sub-Clock Oscillator Control
0x34	1	lococr	LOCO Control
0x35	1	ilococr	IWDT Oscillator Control
0x36	1	hococr	HOCO Control
0x37	1	hococr2	HOCO Control 2
0x38	4	reserved	-
0x3C	1	oscovfsr	Oscillation Stabilization Flag
0x3D	1	reserved	-
0x3E	2	ckocr	Clock Output Control Register
0x40	1	ostdcr	Oscillation Stop Detection Control
0x41	1	ostdsr	Oscillation Stop Detection Status

Offset	Size	Field	Description
Total	66		

Clock Initialization Example

```
// Initialize system to 240 MHz from 24 MHz main oscillator
volatile rx_system_regs_t* sys = system_regs();

// 1. Unlock register protection
*prcr_reg() = k_rx_prcr_unlock_prc0_prc1;

// 2. Enable main oscillator
sys->mosccr = 0x00; // Start main oscillator

// 3. Wait for oscillator stabilization
while (!(sys->oscovfsr & 0x01)) { }

// 4. Configure PLL (24 MHz x 10 = 240 MHz)
sys->pllcr = 0x0913; // STC=9 (x10), PLIDIV=1 (/1)
sys->pllcr2 = 0x00; // Enable PLL

// 5. Wait for PLL stabilization
while (!(sys->oscovfsr & 0x04)) { }

// 6. Set MEMWAIT for >120 MHz operation
*memwait_reg() = k_memwait_one_wait;

// 7. Switch to PLL
sys->sckcr3 = 0x0400; // CKSEL = PLL

// 8. Re-lock protection
*prcr_reg() = k_rx_prcr_lock;
```

Module Stop Example

```
// Enable CMT0 module (clear bit to enable)
*prcr_reg() = k_rx_prcr_unlock_prc1; // Unlock MSTPCR
system_regs()->mstpcra &= ~(1UL « 15); // Enable CMT0
*prcr_reg() = k_rx_prcr_lock;

// Enable USB0 module
*prcr_reg() = k_rx_prcr_unlock_prc1;
system_regs()->mstpcrb &= ~(1UL « k_mstpb_usb0);
*prcr_reg() = k_rx_prcr_lock;
```

Note

PRCR (Protection Register) is NOT in this struct - it's at 0x000803FE. Use [prcr_reg\(\)](#) accessor instead.

Invariant

sizeof(rx_system_regs_t) == 66 bytes (0x42)
All register offsets match RX72N Manual Ch05

Warning

Most registers require PRCR unlock before modification

Attention

MEMWAIT must be set before ICLK > 120 MHz

Collaboration diagram for rx_system_regs_t:

Data Fields

volatile uint8_t	bckcr	External Bus Clock Control Register (BCKCR) @ 0x30. Controls external bus clock output
volatile uint16_t	ckocr	Clock Output Control Register (CKOCR) @ 0x3E. Controls CLKOUT pin output source and divider See also ckocr_bits_t for bit field definitions

volatile uint8_t	hococr	High-Speed On-Chip Oscillator Control (HOCOOCR) @ 0x36. Controls HOCO
volatile uint8_t	hococr2	High-Speed On-Chip Oscillator Control 2 (HOCOOCR2) @ 0x37. HOCO frequency selection
volatile uint8_t	ilococr	IWDT-Dedicated Oscillator Control (ILOCOOCR) @ 0x35. Controls IWDT oscillator (120 kHz)
volatile uint8_t	lococr	Low-Speed On-Chip Oscillator Control (LOCOOCR) @ 0x34. Controls LOCO (240 kHz)
volatile uint16_t	mdmonr	Mode Monitor Register (MDMONR) @ 0x00. Read-only - indicates current operating mode
volatile uint8_t	mosccr	Main Clock Oscillator Control Register (MOSCCR) @ 0x32. Controls main oscillator (24 MHz crystal)
volatile uint32_t	mstpcra	Module Stop Control Register A (MST-PCRA) @ 0x10. Controls CMT, DTC, DMAC module power. Bit=1 stops module.
volatile uint32_t	mstpcrb	Module Stop Control Register B (MST-PCRB) @ 0x14. Controls USB, CRC, SCI, RSPI module power. Bit=1 stops module.
volatile uint32_t	mstpcrc	Module Stop Control Register C (MST-PCRC) @ 0x18. Controls RAM, Flash module power
volatile uint32_t	mstpcrd	Module Stop Control Register D (MST-PCRD) @ 0x1C. Controls ADC, DAC, MTU, GPTW module power. Bit=1 stops module.

volatile uint8_t	oscovfsr	Oscillation Stabilization Flag Register (OSCOVFSR) @ 0x3C. Indicates when oscillators are stable (1=stable, 0=not stable): • Bit 0 (MOOVF): Main clock oscillation stable • Bit 1 (SOOVF): Sub-clock oscillation stable • Bit 2 (PLOVF): PLL clock oscillation stable • Bit 3 (HCOVF): HOCO clock oscillation stable • Bit 4 (ILCOVF): IWDG-dedicated clock oscillation stable • Bit 5 (PPLOVF): PPLL clock oscillation stable • Bits 7:6: Reserved
volatile uint8_t	ostdcr	Oscillation Stop Detection Control (OSTDCR) @ 0x40. Enables oscillation stop detection
volatile uint8_t	ostdsr	Oscillation Stop Detection Status (OSTDSR) @ 0x41. Indicates oscillation stop detection status
volatile uint16_t	pllcr	PLL Control Register (PLLCR) @ 0x28. Sets PLL multiplication factor and input divider
volatile uint8_t	pllcr2	PLL Control Register 2 (PLLCR2) @ 0x2A. PLL enable (0=enabled, 1=disabled)
uint8_t	reserved0↵ [k_system_reserved_02_05]	Reserved @ 0x02-0x05
uint8_t	reserved1↵ [k_system_reserved_0a_0b]	Reserved @ 0x0A-0x0B
uint8_t	reserved2↵ [k_system_reserved_0e_0f]	Reserved @ 0x0E-0x0F
uint8_t	reserved3↵ [k_system_reserved_2b_2f]	Reserved @ 0x2B-0x2F
uint8_t	reserved4 [k_system_reserved_31]	Reserved @ 0x31
uint8_t	reserved5↵ [k_system_reserved_38_3b]	Reserved @ 0x38-0x3B
uint8_t	reserved6 [k_system_reserved_3d]	Reserved @ 0x3D
volatile uint16_t	sbycr	Standby Control Register (SBYCR) @ 0x0C. Controls standby mode (SSBY bit)

volatile uint32_t	sckcr	System Clock Control Register (SCKCR) @ 0x20. Sets division ratios for ICLK, PCLKA, PCLKB, PCLKC, PCLKD, FCLK, BCLK
volatile uint16_t	sckcr2	System Clock Control Register 2 (SCKCR2) @ 0x24. Sets UCK (USB clock) division ratio
volatile uint16_t	sckcr3	System Clock Control Register 3 (SCKCR3) @ 0x26. Selects system clock source (CKSEL bits)
volatile uint8_t	sosccr	Sub-Clock Oscillator Control Register (SOSCCR) @ 0x33. Controls sub-clock oscillator (32.768 kHz)
volatile uint16_t	syscr0	System Control Register 0 (SYSCR0) @ 0x06. Controls ROM/RAM enable and external bus settings
volatile uint16_t	syscr1	System Control Register 1 (SYSCR1) @ 0x08. Controls RAM wait states

8.59.2.2 struct rx_rstsr01_regs_t

Reset Status Registers 0 and 1 (contiguous).

RSTSR0 and RSTSR1 are adjacent in memory at 0x0008C290-0x0008C291.

Definition at line 973 of file [rx72n_system_regs.h](#).

Collaboration diagram for rx_rstsr01_regs_t:

Data Fields

volatile uint8_t	rstsr0	Reset Status Register 0 (voltage, power-on)
volatile uint8_t	rstsr1	Reset Status Register 1 (cold/warm start)

8.59.3 Enumeration Type Documentation

8.59.3.1 ckocr_bits_t

```
enum ckocr_bits_t : uint16_t
```

Clock Output Control Register (CKOCR) bit definitions.

Controls the clock output on CLKOUT pin. Can output various system clocks divided by configurable ratio.

Register Layout (16-bit @ offset 0x3E)

Bit	Field	Description
7:↔ 0	-	Reserved
10:↔ 8	CKOSEL	Clock output source select
11	-	Reserved
14:12	CKODIV	Clock output divider
15	CKOSTP	Clock output stop (0=run, 1=stop)

Clock Output Sources (CKOSEL)

Value	Source	Description
0	LOCO	Low-speed on-chip oscillator
1	HOCO	High-speed on-chip oscillator
2	Main clock	Main oscillator
3	Sub-clock	Sub-clock oscillator
4	PLL	PLL output

Clock Output Dividers (CKODIV[2:0
at bits 14:12])

Value	Divider	Output Frequency
000	$\frac{f}{1}$	f (source frequency)
001	$\frac{f}{2}$	$\frac{f}{2}$
010	$\frac{f}{4}$	$\frac{f}{4}$
011	$\frac{f}{8}$	$\frac{f}{8}$
100	/16	f/16
other	–	PROHIBITED

Clock Output Sources (CKOSEL[2:0
at bits 10:8])

Value	Source
000	LOCO
001	HOCO
010	Main clock
011	Sub-clock
100	PLL circuit
110	PPLL circuit
other	PROHIBITED

Warning

Clock output disabled by default (CKOSTP = 1)
CKODIV values 5, 6, 7 are PROHIBITED (max divisor is /16)

Note

Requires PRCR unlock (PRC0) before modification

```

8.59.3.2 mdmonr`bits`

```
enum mdmonr_bits_t : uint16_t
```

Mode Monitor Register (MDMONR) bit definitions.

Read-only register indicating MCU mode pin status at reset. Located at address 0x00080000.

Register Layout (16-bit @ offset 0x00)

Bit	Field	Description
0	MD	MD Pin Status Flag (read-only)
15↔ 1	-	Reserved (read as 0)

MD Pin Modes (at reset)

- MD = 0: Boot mode (low level on MD pin)
- MD = 1: Single-chip mode (high level on MD pin)

Note

Manual ref: Ch03 section 3.2.1

Since

Version 1.0.0

Enumerator

k_mdmonr_md	MD pin status (0=low/boot, 1=high/single-chip)
k_mdmonr_md_mask	MD bit mask

Definition at line 210 of file [rx72n_system_regs.h](#).

```
00210      : uint16_t {
00211  k_mdmonr_md      = 0x0001U, /**< MD pin status (0=low/boot, 1=high/single-chip) */
00212  k_mdmonr_md_mask = 0x0001U, /**< MD bit mask */
00213 } mdmonr_bits_t;
```

8.59.3.3 pllcr2_bits_t

```
enum pllcr2_bits_t : uint8_t
```

PLL Control Register 2 (PLLCR2) bit definitions.

Controls PLL enable/disable. Note inverted logic: 0 = enabled, 1 = stopped.

Register Layout (8-bit @ offset 0x2A)

Bit	Field	Description
0	PLEN	PLL enable (0=run, 1=stopped)
7↔ 1	-	Reserved

Warning

Inverted logic! 0 = PLL running, 1 = PLL stopped

Note

Must wait for OSCOVFSR.PLOVF before switching clock to PLL

Requires PRCR unlock (PRC0) before modification

Manual Ch09 section 9.2.4

Since

Version 1.0.0

Enumerator

k_pllcr2_pll_running	PLL enabled (running)
k_pllcr2_pll_stopped	PLL disabled (stopped)

Definition at line 623 of file [rx72n_system_regs.h](#).

```
00623      : uint8_t {
00624  k_pllcr2_pll_running = 0x00, /**< PLL enabled (running) */
00625  k_pllcr2_pll_stopped = 0x01, /**< PLL disabled (stopped) */
00626 } pllcr2_bits_t;
```

8.59.3.4 pllcr_bits_t

```
enum pllcr\_bits\_t : uint16_t
```

PLL Control Register (PLLCR) bit definitions.

Controls PLL input divider, output multiplier, and source selection. PLL output frequency = (Input / PLIDIV) x (STC + 1)

Register Layout (16-bit @ offset 0x28)

Bits	Field	Description
1:↔ 0	PLIDIV	PLL input divider (00=/1, 01=/2, 10=/3)
3:↔ 2	-	Reserved
4	PLLSRCSEL	PLL source (0=main osc, 1=HOCO)
7:↔ 5	-	Reserved

Bits	Field	Description
13:8	STC	PLL multiplier (value N -> x(N+1))
15:14	-	Reserved

PLIDIV Encoding (bits 1:0)

Value	Divider	Note
00	1	No division
01	2	
10	3	
11	–	PROHIBITED

STAR Project PLL Configuration

Input: 24 MHz main oscillator Target: 240 MHz PLL output Calculation: $24 \text{ MHz} / 1 \times 10 = 240 \text{ MHz}$

- PLIDIV = 00 (divide by 1) -> 24 MHz
- STC = 0x09 (multiply by 10) -> 240 MHz
- PLLSRCSEL = 0 (main oscillator source)
- PLLCR = 0x0900

Warning

PLL must be stopped (PLLCR2.PLEN = 1) before changing PLLCR

Note

Requires PRCR unlock (PRC0) before modification

00941 } rx_module_stop_bits_a_t;
```

8.59.3.12 rx`module`stop`bits`b`b`it

```
enum rx_module_stop_bits_b_t : uint8_t
```

Module stop bits for MSTPCRB register.

Enumerator

k_mstpb_usb0	USB0 module stop bit in MSTPCRB
k_mstpb_crc	CRC module stop bit in MSTPCRB

Definition at line 944 of file [rx72n_system_regs.h](#).

```
00944         : uint8_t {
00945   k_mstpb_usb0 = 19, /**< USB0 module stop bit in MSTPCRB */
00946   k_mstpb_crc = 23, /**< CRC module stop bit in MSTPCRB */
00947 } rx_module_stop_bits_b_t;
```

8.59.3.13 rx`ppll`addresses`b`b`it

```
enum rx_ppll_addresses_t : uintptr_t
```

PPLL register addresses.

PPLL (PLL for specific purposes) generates the 48 MHz USB clock (UCLK). Must be configured for USB functionality. Reference: RX72N manual Ch09, PPLL frequency synthesizer section.

Enumerator

k_pllcr_addr	PPLL Control Register @ 0x00080048
k_pllcr2_addr	PPLL Control Register 2 @ 0x0008004A
k_pllcr3_addr	PPLL Control Register 3 @ 0x0008004B (PPLCK divider)

Definition at line 1117 of file [rx72n_system_regs.h](#).

```
01117         : uintptr_t {
01118   k_pllcr_addr = 0x00080048, /**< PPLL Control Register @ 0x00080048 */
01119   k_pllcr2_addr = 0x0008004A, /**< PPLL Control Register 2 @ 0x0008004A */
01120   k_pllcr3_addr = 0x0008004B, /**< PPLL Control Register 3 @ 0x0008004B (PPLCK divider) */
01121 } rx_ppll_addresses_t;
```

8.59.3.14 rx_ppll_config_t

```
enum rx_ppll_config_t : uint16_t
```

PPLL configuration values.

PPLL generates 240 MHz internal clock from 24 MHz main oscillator. PPLLCR3 then divides by 5 to produce 48 MHz USB clock (UCLK). Calculation: 24 MHz * 10 = 240 MHz (PPLL output); 240 / 5 = 48 MHz (UCLK)

- PPLIDIV[1:0] = 00 (divide input by 1, binary 00)
- PPLSTC[5:0] = 13h (multiply by x10.0, STC=19=0b010011 at bits 13:8; formula (STC+1)/2=mult)
- PPLSRCSEL = 0 (main clock source, shared with PLL via PLLCR.PLLSRCSEL)
- PPLLCR = 0x1300

Per manual Ch09 section 9.2.23 (p366): PPLSTC minimum valid value is 0b010011 (x10.0). Settings below x10.0 are prohibited – PPLL output must be 120-240 MHz.

Enumerator

k_ppll_config_48mhz	PPLLCR: PPLSTC=19 (x10.0), PPLIDIV=00 (/1): 24MHz*10=240MHz
---------------------	---

Definition at line 1137 of file rx72n_system_regs.h.

```
01137      : uint16_t {
01138  k_ppll_config_48mhz = 0x1300, /**< PPLLCR: PPLSTC=19 (x10.0), PPLIDIV=00 (/1): 24MHz*10=240MHz */
01139 } rx_ppll_config_t;
```

8.59.3.15 rx_ppll_control_t

```
enum rx_ppll_control_t : uint8_t
```

PPLL control values.

Enumerator

k_ppll_enabled	PPLLCR2: Enable PPLL
k_ppll_disabled	PPLLCR2: Disable PPLL

Definition at line 1157 of file rx72n_system_regs.h.

```
01157      : uint8_t {
01158  k_ppll_enabled = 0x00, /**< PPLLCR2: Enable PPLL */
01159  k_ppll_disabled = 0x01, /**< PPLLCR2: Disable PPLL */
01160 } rx_ppll_control_t;
```

8.59.3.16 rx_ppll_flags_t

```
enum rx_ppll_flags_t : uint8_t
```

PPLL stabilization flag in OSCOVFSR.

OSCOVFSR bit layout (manual Ch09 section 9.2.14):

- b0 MOOVF: Main clock oscillation stabilization flag
- b1 SOOVF: Sub-clock oscillation stabilization flag
- b2 PLOVF: PLL clock oscillation stabilization flag
- b3 HCOVF: HOCO clock oscillation stabilization flag
- b4 ILCOVF: IWDG-dedicated clock oscillation stabilization flag
- b5 PPLOVF: PPLL clock oscillation stabilization flag

Enumerator

k_ppll_stable_flag	OSCOVFSR: PPLOVF at bit 5 (0x20); NOT bit 3
--------------------	---

Definition at line 1173 of file rx72n_system_regs.h.

```
01173 : uint8_t {
01174 k_ppll_stable_flag = 0x20, /**< OSCOVFSR: PPLOVF at bit 5 (0x20); NOT bit 3 */
01175 } rx_ppll_flags_t;
```

8.59.3.17 rx_pllcr3_config_t

```
enum rx_pllcr3_config_t : uint8_t
```

PPLLCR3 frequency divider values.

PPLLCR3 PPLCK[3:0] selects the division ratio applied to the PPLL output before it reaches the USB clock (UCLK) pin via PACKCR.UPLLSEL=1. Per manual Ch09 section 9.2.25 (p368): 0001=/2, 0010=/3, 0011=/4, 0100=/5 (settings other than these are prohibited) Set AFTER PPLL is operating and stable (PPLOVF=1), while USB is stopped.

Enumerator

k_pllcr3_div5	PPLLCR3: PPLCK=0100=/5, 240MHz/5=48MHz USB (manual p368)
---------------	--

Definition at line 1150 of file rx72n_system_regs.h.

```
01150 : uint8_t {
01151 k_pllcr3_div5 = 0x04, /**< PPLLCR3: PPLCK=0100=/5, 240MHz/5=48MHz USB (manual p368) */
01152 } rx_pllcr3_config_t;
```

8.59.3.18 rx`prcr`offset``t`

```
enum rx_prcr_offset_t : uint16_t
```

PRCR register offset from system register base address.

PRCR is not part of `rx_system_regs_t`; it sits at base+0x3FE.

Since

Version 1.0.0

Enumerator

k_prcr_from_sys_base	PRCR offset from system base (NOT in system struct)
----------------------	---

Definition at line 1287 of file `rx72n_system_regs.h`.

```
01287      : uint16_t {
01288  k_prcr_from_sys_base = 0x03FE, /**< PRCR offset from system base (NOT in system struct) */
01289 } rx_prcr_offset_t;
```

8.59.3.19 rx`rstsr01`layout``t`

```
enum rx_rstsr01_layout_t : uint8_t
```

Expected size and member offsets for `rx_rstsr01_regs_t`.

Since

Version 1.0.0

Enumerator

k_rstsr01_struct_size	Total size of <code>rx_rstsr01_regs_t</code> (2 bytes)
k_rstsr0_member_off	Byte offset of rstsr0 member
k_rstsr1_member_off	Byte offset of rstsr1 member

Definition at line 1275 of file `rx72n_system_regs.h`.

```
01275      : uint8_t {
01276  k_rstsr01_struct_size = 2, /**< Total size of rx_rstsr01_regs_t (2 bytes) */
01277  k_rstsr0_member_off  = 0, /**< Byte offset of rstsr0 member */
01278  k_rstsr1_member_off  = 1, /**< Byte offset of rstsr1 member */
01279 } rx_rstsr01_layout_t;
```

8.59.3.20 rx_rstsr_addresses_t

```
enum rx_rstsr_addresses_t : uintptr_t
```

Reset status register addresses.

IMPORTANT: RSTSR registers are NOT contiguous in memory!

- RSTSR0/1 are adjacent at 0x0008C290-0x0008C291
- RSTSR2 is at a separate address 0x000800C0 Verified against RX72N Group User's Manual Hardware (R01UH0824EJ0120 Rev.1.20)

Enumerator

k_rstsr0_addr	Reset Status Register 0 address (page 286)
k_rstsr1_addr	Reset Status Register 1 address (page 288)
k_rstsr2_addr	Reset Status Register 2 address (page 289)

Definition at line 962 of file [rx72n_system_regs.h](#).

```
00962     : uintptr_t {
00963   k_rstsr0_addr = 0x0008C290, /**< Reset Status Register 0 address (page 286) */
00964   k_rstsr1_addr = 0x0008C291, /**< Reset Status Register 1 address (page 288) */
00965   k_rstsr2_addr = 0x000800C0, /**< Reset Status Register 2 address (page 289) */
00966 } rx_rstsr_addresses_t;
```

8.59.3.21 rx_swrr_addresses_t

```
enum rx_swrr_addresses_t : uintptr_t
```

Software Reset Register (SWRR) address.

Writing 0xA501 to this register triggers an immediate software reset. Reference: RX72N manual Ch06 section 6.2.4, page 290.

Enumerator

k_swrr_addr	Software Reset Register address (16-bit)
-------------	--

Definition at line 1029 of file [rx72n_system_regs.h](#).

```
01029     : uintptr_t {
01030   k_swrr_addr = 0x000800C2, /**< Software Reset Register address (16-bit) */
01031 } rx_swrr_addresses_t;
```

8.59.3.22 rx_swrr_values_t

```
enum rx_swrr_values_t : uint16_t
```

Software Reset Register value.

Write this value to SWRR to trigger a software reset. The MCU will reset after the internal reset time (tRESW2) elapses.

Warning

This immediately resets the MCU - ensure all critical state is saved.

Enumerator

k_swrr_reset_key	Write this value to trigger software reset
------------------	--

Definition at line 1040 of file [rx72n_system_regs.h](#).

```
01040      : uint16_t {
01041    k_swrr_reset_key = 0xA501, /**< Write this value to trigger software reset */
01042  } rx_swrr_values_t;
```

8.59.3.23 rx_system_addr_refs_t

```
enum rx_system_addr_refs_t : uintptr_t
```

Expected hardware addresses per RX72N Hardware Manual.

Each member documents the address mandated by the hardware manual chapter cited in the comment. Used in static_assert to cross-check address enum definitions against the manual reference values.

Since

Version 1.0.0

Enumerator

k_ref_system_base	System register base address (Ch05, Sec 5.2.2)
k_ref_prcr	PRCR address – outside system struct (Ch05)
k_ref_rstsr0	RSTSR0 address (Ch05)
k_ref_rstsr1	RSTSR1 address (Ch05)
k_ref_rstsr2	RSTSR2 address (Ch05)
k_ref_swrr	SWRR address (Ch06)
k_ref_memwait	MEMWAIT address (Ch09)
k_ref_pllcr	PPLLCR address (Ch09)
k_ref_pllcr2	PPLLCR2 address (Ch09)
k_ref_pllcr3	PPLLCR3 address (Ch09 section 9.2.25, p368)

Definition at line 1221 of file [rx72n_system_regs.h](#).

```

8.59.3.24 rx_system_addresses_t

```
enum rx_system_addresses_t : uintptr_t
```

System register base addresses.

Base addresses for system control registers. Note that system registers are spread across multiple non-contiguous memory regions.

Address Map

Address	Register/Block	Description
0x00080000	System Base	Main system register block
0x000803FE	PRCR	Register protection control

Warning

PRCR is NOT in the main system block - use [prcr_reg\(\)](#) accessor

See also

[system_regs\(\)](#) Main system register accessor

00155     /**
00156      * @brief PRCR (Protection Register) address (0x000803FE)
00157      * @details Located separately from main system block. Used to protect
00158      * clock, module stop, and voltage detection registers from accidental writes.
00159      * @warning Not part of rx_system_regs_t structure
00160      */
00161     k_pcr_addr = 0x000803FE,
00162 } rx_system_addresses_t;
```

8.59.3.25 rx_system_struct_layout_t

```
enum rx_system_struct_layout_t : uint8_t
```

Expected size and member offsets for [rx_system_regs_t](#).

Authoritative per RX72N Hardware Manual Ch05, Section 5.2.2 address map. Used in static_assert to verify the compiler produces the correct layout.

Since

Version 1.0.0

Enumerator

k_sys_regs_size	Total size of rx_system_regs_t (66 bytes, 0x00-0x41)
k_sys_reg_mdmmonr_off	Offset of MDMONR (mode monitor)
k_sys_reg_syscr0_off	Offset of SYSCR0
k_sys_reg_syscr1_off	Offset of SYSCR1
k_sys_reg_sbycr_off	Offset of SBYCR (standby control)
k_sys_reg_mstpcra_off	Offset of MSTPCRA
k_sys_reg_mstpcrb_off	Offset of MSTPCRB
k_sys_reg_mstpcrc_off	Offset of MSTPCRC
k_sys_reg_mstpcrd_off	Offset of MSTPCRD
k_sys_reg_sckcr_off	Offset of SCKCR (system clock control)
k_sys_reg_sckcr2_off	Offset of SCKCR2
k_sys_reg_sckcr3_off	Offset of SCKCR3 (clock source select)
k_sys_reg_pllcr_off	Offset of PLLCR
k_sys_reg_pllcr2_off	Offset of PLLCR2 (PLL enable)
k_sys_reg_bckcr_off	Offset of BCKCR (external bus clock)
k_sys_reg_mosccr_off	Offset of MOSCCR (main oscillator control)
k_sys_reg_sosccr_off	Offset of SOSCCR (sub-clock control)
k_sys_reg_lococr_off	Offset of LOCOCR (LOCO control)
k_sys_reg_ilococr_off	Offset of ILOCOCR (IWDT oscillator control)
k_sys_reg_hococr_off	Offset of HOCOCR (HOCO control)
k_sys_reg_hococr2_off	Offset of HOCOCR2 (HOCO frequency)
k_sys_reg_oscovfsr_off	Offset of OSCOVFSR (oscillation stable flags)
k_sys_reg_ckocr_off	Offset of CKOCR (clock output control)
k_sys_reg_ostdcr_off	Offset of OSTDCR (oscillation stop detect control)
k_sys_reg_ostdsr_off	Offset of OSTDSR (oscillation stop detect status)

```

8.59.3.26 sckcr3`cksel` t

```
enum sckcr3_cksel_t : uint16_t
```

System clock source selection (SCKCR3 CKSEL field).

Selects which oscillator/PLL output is used as the system clock source. This is the clock that feeds into SCKCR dividers.

Clock Sources (CKSEL[2:0
at bits 10:8 of SCKCR3])

Value	Source	Typical Frequency	Use Case
0	LOCO	240 kHz (typ)	Low power mode
1	HOCO	16-20 MHz (config)	Boot, low power
2	Main clock	24 MHz (STAR)	External crystal
3	Sub-clock	32.768 kHz	RTC, ultra low power
4	PLL	240 MHz (STAR)	Normal operation
other	—	PROHIBITED	—

Note

PPLL is NOT a valid SCKCR3 CKSEL option. PPLL is used only as the USB clock source, selected via PACKCR.UPLLSEL.

STAR Project Settings

- Boot: LOCO (default after reset)
- Normal operation: PLL @ 240 MHz

Warning

Switching clock sources requires waiting for oscillator stabilization

Note

Requires PRCR unlock (PRC0) before modification

Version 1.0.0

Enumerator

k_sckcr3_cksel_loco	LOCO (Low-speed On-Chip Oscillator, 240 kHz)
k_sckcr3_cksel_hoco	HOCO (High-speed On-Chip Oscillator, 16-20 MHz)
k_sckcr3_cksel_main	Main clock oscillator (STAR: 24 MHz crystal)
k_sckcr3_cksel_subclock	Sub-clock oscillator (32.768 kHz)
k_sckcr3_cksel_pll	PLL circuit (STAR: 240 MHz). Values 5-7 are prohibited.
k_sckcr3_cksel_mask	CKSEL field mask (bits 10:8)

Definition at line 525 of file [rx72n_system_regs.h](#).

```

00525     : uint16_t {
00526 k_sckcr3_cksel_loco    = 0x0000, /**< LOCO (Low-speed On-Chip Oscillator, 240 kHz) */
00527 k_sckcr3_cksel_hoco    = 0x0100, /**< HOCO (High-speed On-Chip Oscillator, 16-20 MHz) */
00528 k_sckcr3_cksel_main    = 0x0200, /**< Main clock oscillator (STAR: 24 MHz crystal) */
00529 k_sckcr3_cksel_subclock = 0x0300, /**< Sub-clock oscillator (32.768 kHz) */
00530 k_sckcr3_cksel_pll     = 0x0400, /**< PLL circuit (STAR: 240 MHz). Values 5-7 are prohibited. */
00531 k_sckcr3_cksel_mask    = 0x0700, /**< CKSEL field mask (bits 10:8) */
00532 } sckcr3_cksel_t;

```

8.59.3.27 sckcr`bits``t`

```
enum sckcr\_bits\_t : uint32_t
```

System Clock Control Register (SCKCR) bit definitions.

32-bit register controlling all main system clock dividers. Each field is 4 bits wide and uses the encoding from [sckcr_divider_t](#).

Register Layout (32-bit @ offset 0x20)

Bits	Field	Clock	STAR Project Setting
3:↔ 0	PCKD	PCLKD	/4 (60 MHz from 240)
7:↔ 4	PCKC	PCLKC	/4 (60 MHz from 240)
11:↔ 8	PCKB	PCLKB	/4 (60 MHz from 240)

Bits	Field	Clock	STAR Project Setting
15:12	PCKA	PCLKA	/2 (120 MHz from 240)
19:16	BCK	BCLK	/2 (120 MHz from 240)
21:20	-	Reserved	-
22	PSTOP0	PCLKA/B	0 (running)
23	PSTOP1	USB	0 (running)
27:24	ICK	ICLK	/1 (240 MHz)
31:28	FCK	FCLK	/4 (60 MHz from 240)

STAR Project Configuration

With 24 MHz main oscillator x PLL(x10) = 240 MHz:

- ICLK = 240 MHz (CPU instruction clock)
- PCLKA = 120 MHz (high-speed peripherals)
- PCLKB = 60 MHz (CMT, WDT, etc.)
- PCLKC = 60 MHz (general peripherals)
- PCLKD = 60 MHz (ADC)
- FCLK = 60 MHz (Flash memory)
- BCLK = 120 MHz (External bus)

Warning

ICLK > 120 MHz requires MEMWAIT = 1 before changing SCKCR

Note

Requires PRCR unlock (PRC0) before modification

00493 } sckcr_bits_t;

```

8.59.3.28 sckcr_divider_t

```
enum sckcr_divider_t : uint8_t
```

Clock divider values for SCKCR fields.

All SCKCR clock divider fields use the same encoding. Value N means divide by 2^N . For example, 0b0010 (2) means divide by 4.

Divider Encoding (for PCKD, PCKC, PCKB, PCKA, ICK, FCK fields)

Bits	Divider	Example (240 MHz input)
0000	$\swarrow$ 1	240 MHz
0001	$\swarrow$ 2	120 MHz
0010	$\swarrow$ 4	60 MHz
0011	$\swarrow$ 8	30 MHz
0100	/16	15 MHz
0101	/32	7.5 MHz
0110	/64	3.75 MHz
other	–	PROHIBITED

Note

The BCK field also accepts 1001 (x1/3) as an additional valid setting.

Warning

Values 0111 and 1000 are PROHIBITED for all SCKCR fields.

8.59.3.29 syscr0`bits`

enum [syscr0_bits_t](#) : uint16_t

System Control Register 0 (SYSCR0) bit definitions.

Controls on-chip ROM enable and external bus enable. Requires key code 0x5A in upper byte for writes. Located at address 0x00080006.

Register Layout (16-bit @ offset 0x06)

Bit	Field	Description
0	ROME	On-Chip ROM Enable
1	EXBE	External Bus Enable
7↔ 2	-	Reserved (write 0)
15↔ 8	KEY[7↔ 0]	Key code (write 0x5A to modify)

Operating Modes

ROME	EXBE	Mode
1	0	Single-chip mode
1	1	On-chip ROM enabled extended mode
0	1	On-chip ROM disabled extended mode
0	0	Single-chip mode (ROM disabled)

Warning

Once ROME is set to 0, it cannot be reverted to 1
Do not modify EXBE while accessing external bus

00256 } syscr0_bits_t;

```

8.59.3.30 syscr1`bits`

enum syscr1_bits_t : uint16_t

System Control Register 1 (SYSCR1) bit definitions.

Controls RAM, ECCRAM, and Standby RAM enable. Located at address 0x00080008.

Register Layout (16-bit @ offset 0x08)

Bit	Field	Description
0	RAME	RAM Enable
5:↵ 1	-	Reserved (read/write as 1)
6	ECCRAME	ECCRAM Enable
7	SBYRAME	Standby RAM Enable
15:↵ 8	-	Reserved (write 0)

Default Value: 0x00FF (all RAM enabled)

- RAME = 1 (RAM enabled)
- Reserved bits 5:1 = 1
- ECCRAME = 1 (ECCRAM enabled)
- SBYRAME = 1 (Standby RAM enabled)

Warning

Do not write 0 to RAME/ECCRAM/SBYRAME during access to that memory

Note

Manual ref: Ch03 section 3.2.3

Since

Version 1.0.0

Enumerator

k_syscr1_rame	RAM Enable (0=disabled, 1=enabled)
k_syscr1_reserved_mask	Reserved bits 5:1 (read/write as 1)

00296 } syscr1_bits_t;

```

8.59.3.31 system`reserved`sizes`t

```
enum system\_reserved\_sizes\_t : uint8_t
```

System register reserved field sizes.

Defines reserved byte counts for gaps in the system register map. These ensure correct structure alignment with hardware.

Since

Version 1.0.0

Enumerator

k_system_reserved_02_05	Reserved @ 0x02-0x05 (between MDMONR and SYSCR0)
k_system_reserved_0a_0b	Reserved @ 0x0A-0x0B (between SYSCR1 and SBYCR)

<code>k_system_reserved_0e_0f</code>	Reserved @ 0x0E-0x0F (between SBYCR and MSTPCRA)
<code>k_system_reserved_2b_2f</code>	Reserved @ 0x2B-0x2F (between PLLCR2 and BCKCR)
<code>k_system_reserved_31</code>	Reserved @ 0x31 (between BCKCR and MOSCCR)
<code>k_system_reserved_38_3b</code>	Reserved @ 0x38-0x3B (between HOCOCR2 and OSCOVFSR)
<code>k_system_reserved_3d</code>	Reserved @ 0x3D (between OSCOVFSR and CKOCR)

00182 } system_reserved_sizes_t;

```

8.59.4 Function Documentation

8.59.4.1 `memwait_reg()`

```
volatile uint8_t * memwait_reg (
    void ) [inline], [static]
```

Get pointer to MEMWAIT register.

Returns

Volatile pointer to MEMWAIT register

Note

CRITICAL: Must set to 1 before increasing ICLK above 120 MHz

Definition at line 1100 of file [rx72n_system_regs.h](#).

```

01101 {
01102     return (volatile uint8_t*)k_memwait_addr;
01103 }

```

References [k_memwait_addr](#).

8.59.4.2 `ppllcr2_reg()`

```
volatile uint8_t * ppllcr2_reg (
    void ) [inline], [static]
```

Get pointer to PPLLCR2 register.

Returns

Volatile pointer to PPLLCR2 register

Definition at line 1190 of file [rx72n_system_regs.h](#).

```

01191 {
01192     return (volatile uint8_t*)k_ppllcr2_addr;
01193 }

```

References [k_ppllcr2_addr](#).

8.59.4.3 ppllcr3_reg()

```
volatile uint8_t * ppllcr3_reg (  
    void )    [inline], [static]
```

Get pointer to PPLLCR3 register.

Returns

Volatile pointer to PPLLCR3 register

Note

Set PPLCK[3:0] while PLL is running and USB module is stopped.

Definition at line 1200 of file [rx72n_system_regs.h](#).

```
01201 {  
01202     return (volatile uint8_t*)k_ppllcr3_addr;  
01203 }
```

References [k_ppllcr3_addr](#).

8.59.4.4 ppllcr_reg()

```
volatile uint16_t * ppllcr_reg (  
    void )    [inline], [static]
```

Get pointer to PPLLCR register.

Returns

Volatile pointer to PPLLCR register

Definition at line 1181 of file [rx72n_system_regs.h](#).

```
01182 {  
01183     return (volatile uint16_t*)k_ppllcr_addr;  
01184 }
```

References [k_ppllcr_addr](#).

8.59.4.5 prcr_reg()

```
volatile uint16_t * prcr_reg (  
    void )    [inline], [static]
```

Get pointer to PRCR (Protection Register).

Returns

Volatile pointer to 16-bit PRCR register

PRCR is at address 0x000803FE, which is NOT contiguous with the main system register block (0x00080000-0x00080041). This accessor provides the correct address for register protection control.

Manual Reference:

RX72N Group User's Manual: Hardware, Chapter 13 (Register Write Protection)

- Address: 0x000803FE (verified against manual)
- Size: 16-bit
- Key: 0xA5 in upper byte required for any write

Note

Use `k_rx_prcr_unlock_*` and `k_rx_prcr_lock` values from `rx_register_protection.h` for unlock/↔ lock operations.

Example:

```
#include "rx_register_protection.h"
*prcr_reg() = k_rx_prcr_unlock_prc1; // Unlock MSTPCR group
system_regs()->mstpcra &= ~(1UL « 15); // Enable CMT0
*prcr_reg() = k_rx_prcr_lock; // Re-lock protection
```

Definition at line 933 of file `rx72n_system_regs.h`.

```
00934 {
00935     return (volatile uint16_t*)k_prcr_addr;
00936 }
```

References `k_prcr_addr`.

Referenced by `internal_configure_adc_unit()`, `internal_configure_registers()`, `internal_disable_doc_clock()`, `internal_enable_cmt_module_clock()`, `internal_enable_doc_clock()`, `internal_enable_eccram_module_clock()`, `internal_enable_gptw_module_clock()`, `internal_enable_sci_clock()`, `internal_enable_tpu_module_clock()`, `internal_module_start()`, `internal_module_stop()`, `internal_riic_release_module_stop()`, `internal_rspi_release_module_stop()`, `internal_tmr_enable_module_clock()`, `riic_init_peripheral()`, `rspi_controller_deinit()`, `rspi_deinit()`, `rx_lpc_enter_deep_software_standby()`, `rx_lpc_enter_sleep()`, `rx_lpc_enter_software_standby()`, `rx_lpc_init()`, `rx_lpc_set_operating_power()`, and `rx_mtu_init_pwm()`.

Here is the caller graph for this function:

8.59.4.6 rstsr01()

```
volatile rx\_rstsr01\_regs\_t *rstsr01 (
    void ) [inline], [static]
```

Get pointer to RSTSR0/RSTSR1 registers.

Returns

Volatile pointer to RSTSR0/1 register structure

Definition at line 982 of file [rx72n_system_regs.h](#).

```
00983 {
00984     return (volatile rx_rstsr01_regs_t*)k_rstsr0_addr;
00985 }
```

References [k_rstsr0_addr](#).

8.59.4.7 rstsr2()

```
volatile uint8_t * rstsr2 (
    void )    [inline], [static]
```

Get pointer to RSTSR2 register.

Returns

Volatile pointer to RSTSR2 register

Note

RSTSR2 is at a separate address from RSTSR0/1

Definition at line 992 of file [rx72n_system_regs.h](#).

```
00993 {
00994     return (volatile uint8_t*)k_rstsr2_addr;
00995 }
```

References [k_rstsr2_addr](#).

8.59.4.8 swrr_reg()

```
volatile uint16_t * swrr_reg (
    void )    [inline], [static]
```

Get pointer to SWRR (Software Reset Register).

Returns

Volatile pointer to 16-bit SWRR register

SWRR is at address 0x000800C2. Writing 0xA501 triggers a software reset.

Warning

Writing to this register causes immediate MCU reset!

Manual Reference:

RX72N Group User's Manual: Hardware, Chapter 6 (Resets), page 290.

Example:

```
// Trigger a software reset (MCU will restart)
*swrr_reg() = k_swrr_reset_key;
// Code never reaches here - MCU resets immediately
```

Definition at line 1063 of file [rx72n_system_regs.h](#).

```
01064 {
01065     return (volatile uint16_t*)k_swrr_addr;
01066 }
```

References [k_swrr_addr](#).

8.59.4.9 system_regs()

```
volatile rx_system_regs_t * system_regs (  
    void )    [inline], [static]
```

Get pointer to system registers.

Returns

Volatile pointer to system register structure

Note

Named `system_regs()` instead of `system()` to avoid naming conflicts

Definition at line 896 of file `rx72n_system_regs.h`.

```
00897 {  
00898     return (volatile rx_system_regs_t*)k_system_base_addr;  
00899 }
```

References `k_system_base_addr`.

Referenced by `internal_configure_adc_unit()`, `internal_disable_doc_clock()`, `internal_enable_cmt_module_clock()`, `internal_enable_doc_clock()`, `internal_enable_eccram_module_clock()`, `internal_enable_gptw_module_clock()`, `internal_enable_sci_clock()`, `internal_enable_tpu_module_clock()`, `internal_module_start()`, `internal_module_stop()`, `internal_riic_release_module_stop()`, `internal_set_mstpcrb_for_channel()`, `internal_tmr_enable_module_clock()`, `riic_init_peripheral()`, `rx_lpc_enter_deep_software_standby()`, `rx_lpc_enter_sleep()`, `rx_lpc_enter_software_standby()` and `rx_mtu_init_pwm()`.

RX72N Temperature Sensor (TEMPS) Register Definitions.

#include <stdint.h>

Include dependency graph for rx72n_temps_regs.h:

Enumerations

- enum `temps_addresses_t` : `uintptr_t` { `k_temps_tscr_addr` = 0x0008C500U , `k_temps_tscdr_addr` = 0xFE7F7D7CU }
- Temperature Sensor register addresses.
- enum `tscr_bits_t` : `uint8_t` {
`k_tscr_tsen_bit` = 0x80U , `k_tscr_tsoe_bit` = 0x10U , `k_tscr_disabled` = 0x00U ,
`k_tscr_sensor_only` = 0x80U ,
`k_tscr_sensor_with_output` = 0x90U , `k_tscr_reserved_mask` = 0x6FU }
- Temperature Sensor Control Register (TSCR) bit definitions.
- enum `temps_timing_t` : `uint16_t` { `k_temps_tstbl_us` = 30U , `k_temps_tostbl_us` = 0U }
- Temperature sensor timing constants.
- enum `temps_calibration_t` : `uint16_t` { `k_temps_cal_temp_celsius` = 125U , `k_temps_adc_full_scale` = 4096U , `k_temps_avcc_mv` = 3300U , `k_temps_slope_uv_per_c` = 4100U }
- Temperature sensor calibration constants.
- enum `temps_mstpcr_t` : `uint32_t` { `k_temps_mstpcrb_bit` = (1U << 8U) }
- Temperature sensor module stop control bits.

Functions

- static volatile `uint8_t` * `temps_tscr_reg` (void)
Get pointer to Temperature Sensor Control Register (TSCR).
- static volatile const `uint32_t` * `temps_tscdr_reg` (void)
Get pointer to Temperature Sensor Calibration Data Register (TSCDR).

8.61.1 Detailed Description

RX72N Temperature Sensor (TEMPS) Register Definitions.

Complete register definitions for the RX72N internal temperature sensor. The temperature sensor outputs a voltage proportional to die temperature, which can be converted to temperature via the 12-bit ADC unit 1.

Temperature Measurement Overview

The RX72N has a built-in temperature sensor that:

1. Outputs voltage proportional to temperature
2. Connects to 12-bit A/D converter unit 1
3. Has factory-programmed calibration data (CAL125 @ 125degC)

Temperature Calculation Formula

$T = (V_s - V_1) / \text{Slope} + 125$ [degC] Where:

- V_s : Measured voltage (from ADC)
- V_1 : Calibration voltage at 125degC = $3.3 \times \text{TSCDR} / 4096$ [V]
- Slope: Temperature slope from Table 63.57 (typ. -4.1 mV/degC)

Register Summary

Register	Address	Size	Description
TSCR	0x0008C500	8	Temperature Sensor Control Register
TSCDR	0xFE7F7D7C	32	Calibration Data (read-only, ROM)

Usage Sequence (from Ch58 manual)

1. Clear module stop bit (MSTPCRB.MSTPC8 = 0)
2. Configure ADC unit 1 for temperature sensor input
3. Set TSCR.TSEN = 1 (start temperature sensor)
4. Wait 30 us for reference voltage stabilization (tTSTBL)
5. Set TSCR.TSOE = 1 (enable output to ADC)
6. Wait 0 us for output stabilization (tOSTBL)
7. Start ADC conversion
8. Read ADC result from ADTSDR register
9. Calculate temperature using formula above

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion
- Rule 2: [OK] N/A (no loops)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] Single-statement accessors
- Rule 5: [OK] Static assertions verify addresses
- Rule 6: [OK] Minimal scope
- Rule 7: [OK] N/A
- Rule 8: [OK] All constants use C23 typed enums
- Rule 9: [OK] No function pointers
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

8.61.2.2 temps_calibration_t

enum [temps_calibration_t](#) : uint16_t

Temperature sensor calibration constants.

Constants for temperature calculation using factory calibration data.

Temperature Calculation

The calibration data (TSCDR) was measured at:

- $T_j = 125\text{degC}$ (junction temperature)
- $AVCC1 = 3.3\text{V}$ (ADC reference voltage)

Note

Manual ref: Ch58 section 58.3.1

Since

Version 1.0.0

Enumerator

k_temps_cal_temp_celsius	Calibration temperature (125degC). Factory calibration performed at this temperature
k_temps_adc_full_scale	ADC full scale value (12-bit = 4096).
k_temps_avcc_mv	ADC reference voltage in millivolts (3300 mV = 3.3V).
k_temps_slope_uv_per_c	Typical temperature slope in uV/degC (absolute value). From Table 63.57: typ. -4.1 mV/degC = -4100 uV/degC Note Actual value varies by chip; two-point calibration recommended

Definition at line 221 of file [rx72n_temps_regs.h](#).

8.61.3 Function Documentation

8.61.3.1 temps_tscdr_reg()

```
volatile const uint32_t * temps_tscdr_reg (
    void ) [inline], [static]
```

Get pointer to Temperature Sensor Calibration Data Register (TSCDR).

Returns a volatile pointer to TSCDR at address 0xFE7F7D7C. This is a 32-bit read-only register containing factory calibration data.

Calibration Data Format

The lower 12 bits contain the ADC value measured at 125degC and 3.3V:

- Bits [11:0]: ADC value (0-4095)
- Bits [31:12]: Reserved (read as 0)

Converting to Voltage

$$V1 = 3.3 \times (\text{TSCDR} \& 0\text{xFFF}) / 4096 \text{ [V]}$$

Returns

Volatile pointer to TSCDR register (32-bit, read-only)

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

On-chip ROM must be enabled (SYSCR0.ROME = 1)

Postcondition

Pointer is valid for the lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

This function is always inlined for zero overhead

Warning

This register is read-only; writes have no effect

Example (Read Calibration):

```
// Read calibration data
uint32_t cal125 = *temps_tscdr_reg() & 0xFFFF;

// Calculate reference voltage at 125degC
// V1 = 3.3 x cal125 / 4096 (in fixed-point or float)
```

See also

[k_temps_tscdr_addr](#) Address constant

Since

Version 1.0.0

Definition at line 353 of file [rx72n_temps_regs.h](#).

```
00354 {
00355     return (volatile const uint32_t*)k_temps_tscdr_addr;
00356 }
```

References [k_temps_tscdr_addr](#).

8.61.3.2 temps_tscr_reg()

```
volatile uint8_t * temps_tscr_reg (
    void ) [inline], [static]
```

Get pointer to Temperature Sensor Control Register (TSCR).

Returns a volatile pointer to TSCR at address 0x0008C500.

Returns

Volatile pointer to TSCR register (8-bit)

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

Temperature sensor module stop (MSTPCRB.MSTPC8) must be cleared

Postcondition

Pointer is valid for the lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

This function is always inlined for zero overhead

Example (Enable Temperature Sensor):

```
// 1. Start temperature sensor
*temps_tscr_reg() = k_tscr_sensor_only;

// 2. Wait for stabilization (30 us)
delay_us(k_temps_tstbl_us);

// 3. Enable output to ADC
*temps_tscr_reg() = k_tscr_sensor_with_output;

// 4. Start ADC conversion (see S12AD1 registers)
```

00001 /**
00002  * @file rx72n_temps_regs.h
00003  * @brief RX72N Temperature Sensor (TEMPS) Register Definitions
00004  *
00005  * @details
00006  * Complete register definitions for the RX72N internal temperature sensor.
00007  * The temperature sensor outputs a voltage proportional to die temperature,
00008  * which can be converted to temperature via the 12-bit ADC unit 1.
00009  *
00010  * @par Temperature Measurement Overview
00011  * The RX72N has a built-in temperature sensor that:
00012  * 1. Outputs voltage proportional to temperature
00013  * 2. Connects to 12-bit A/D converter unit 1
00014  * 3. Has factory-programmed calibration data (CAL125 @ 125degC)
00015  *
00016  * @par Temperature Calculation Formula
00017  *  $T = (V_s - V_1) / \text{Slope} + 125 \text{ [degC]}$ 
00018  * Where:
00019  * -  $V_s$ : Measured voltage (from ADC)
00020  * -  $V_1$ : Calibration voltage at 125degC =  $3.3 \times \text{TSCDR} / 4096 \text{ [V]}$ 
00021  * - Slope: Temperature slope from Table 63.57 (typ. -4.1 mV/degC)
00022  *
00023  * @par Register Summary
00024  * | Register | Address | Size | Description |
00025  * |-----|-----|-----|-----|
00026  * | TSCR | 0x0008C500 | 8 | Temperature Sensor Control Register |
00027  * | TSCDR | 0xFE7F7D7C | 32 | Calibration Data (read-only, ROM) |
00028  *
00029  * @par Usage Sequence (from Ch58 manual)
00030  * 1. Clear module stop bit (MSTPCRB.MSTPC8 = 0)
00031  * 2. Configure ADC unit 1 for temperature sensor input
00032  * 3. Set TSCR.TSEN = 1 (start temperature sensor)
00033  * 4. Wait 30 us for reference voltage stabilization (tTSTBL)
00034  * 5. Set TSCR.TSOE = 1 (enable output to ADC)
00035  * 6. Wait 0 us for output stabilization (tOSTBL)
00036  * 7. Start ADC conversion
00037  * 8. Read ADC result from ADTSDR register
00038  * 9. Calculate temperature using formula above
00039  *
00040  * @par NASA Power of 10 Compliance
00041  * - Rule 1: [OK] No goto, setjmp, or recursion
00042  * - Rule 2: [OK] N/A (no loops)
00043  * - Rule 3: [OK] No dynamic memory allocation
00044  * - Rule 4: [OK] Single-statement accessors

TMR Software Configurable Interrupt B source numbers.

Functions

- static volatile `rx_tmr_channel_regs_t * tmr0` (void)
Get pointer to TMR0 channel register block (unit 0 even channel).
- static volatile `rx_tmr_channel_regs_t * tmr1` (void)
Get pointer to TMR1 channel register block (unit 0 odd channel).
- static volatile `rx_tmr_channel_regs_t * tmr2` (void)
Get pointer to TMR2 channel register block (unit 1 even channel).
- static volatile `rx_tmr_channel_regs_t * tmr3` (void)
Get pointer to TMR3 channel register block (unit 1 odd channel).
- static volatile `rx_tmr_cascade_regs_t * tmr01_cascade` (void)
Get pointer to TMR01 cascaded 16-bit register view.
- static volatile `rx_tmr_cascade_regs_t * tmr23_cascade` (void)
Get pointer to TMR23 cascaded 16-bit register view.

8.63.1 Detailed Description

RX72N 8-Bit Timer (TMRb) Register Definitions.

Register definitions for the TMR peripheral which provides 4 channels of 8-bit timers (TMR0..TMR3) organized into two units. Each unit contains two channels that may operate independently (two 8-bit counters) or cascaded (one 16-bit counter, TMR01 or TMR23).

Channel and Unit Layout

Unit	Channels	Module Stop Bit	Cascade Name
0	TMR0, TMR1	MSTPCRA.MSTPA5	TMR01
1	TMR2, TMR3	MSTPCRA.MSTPA4	TMR23

Key Features

- 8-bit up-counter with two compare-match registers (TCORA, TCORB)
- Optional 16-bit cascaded mode (even + odd channel concatenated)
- Counter clear on compare match A, compare match B, or external reset
- 8 clock sources per channel (external edge/level, PCLK dividers, cascade)
- Compare match A/B and overflow interrupts via SELECTB
- Dedicated TMO output pin per channel for hardware pulse generation

Register Map Overview (Unit 0 / Unit 1)

Even Ch Addr	Odd Ch Addr	Register	Size	Description
0x00088200	0x00088201	TCR	8	Timer Control
0x00088202	0x00088203	TCSR	8	Timer Control/Status
0x00088204	0x00088205	TCORA	8	Time Constant A
0x00088206	0x00088207	TCORB	8	Time Constant B
0x00088208	0x00088209	TCNT	8	Timer Counter
0x0008820A	0x0008820B	TCCR	8	Timer Counter Control
0x0008820C	0x0008820D	TCSTR	8	Timer Counter Start (ELC)

Unit 1 uses the same layout offset +0x10 (TMR2 base 0x00088210, TMR3 0x00088211).

NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: N/A (no loops in register definitions)
- Rule 3: No dynamic memory allocation
- Rule 4: All accessor functions are single-statement
- Rule 5: N/A (hardware layer)
- Rule 6: Minimal scope - inline accessors only
- Rule 7: N/A (no return values to check)
- Rule 8: All constants use C23 typed enums
- Rule 9: No function pointers
- Rule 10: Compiles with -Wall -Wextra -Werror

8.63.2 Data Structure Documentation

8.63.2.1 struct rx_tmr_channel_regs_t

TMR single-channel register block.

Register block for one TMR channel accessed via byte strides of 2. Because even and odd channels share the same 16-byte block at different parity offsets, accessing TMRn directly requires striding by 2 bytes per field; this structure therefore represents ONE channel with the interleaved odd byte reserved.

The layout follows the byte addressing in Table 30.1:

- TMR0.TCR @ 0x88200, TMR1.TCR @ 0x88201
- TMR0.TCSR @ 0x88202, TMR1.TCSR @ 0x88203
- TMR0.TCORA @ 0x88204, TMR1.TCORA @ 0x88205
- TMR0.TCORB @ 0x88206, TMR1.TCORB @ 0x88207
- TMR0.TCNT @ 0x88208, TMR1.TCNT @ 0x88209
- TMR0.TCCR @ 0x8820A, TMR1.TCCR @ 0x8820B
- TMR0.TCSTR @ 0x8820C, TMR1.TCSTR @ 0x8820D

Pointer returned by [tmr0\(\)](#)/tmr2() points to the even byte; pointer returned by [tmr1\(\)](#)/tmr3() points to the odd byte. Each struct field therefore accesses the channel's own byte.

Invariant

`sizeof(rx_tmr_channel_regs_t) == 14` (spans byte 0 through 12)

8.63.2.2 struct rx_tmr_cascade_regs_t

TMR cascaded 16-bit register view (TMR01 or TMR23).

When two TMR channels in the same unit are cascaded, TCORA, TCORB, TCNT, and TCCR may be accessed as 16-bit values with the even channel forming the upper byte and the odd channel forming the lower byte.

Only TCORA/TCORB/TCNT/TCCR have defined 16-bit semantics (manual Table 30.4); the other bytes are kept per-channel via the per-channel register block accessed through [tmr0\(\)](#)/[tmr1\(\)](#)/[tmr2\(\)](#)/[tmr3\(\)](#).

Invariant

```
sizeof(rx_tmr_cascade_regs_t) == 12
```

8.63.3 Enumeration Type Documentation

8.63.3.1 rx_tmr_addresses_t

```
enum rx_tmr_addresses_t : uintptr_t
```

TMR channel base addresses.

Base addresses for each TMR channel (even channels at even byte offsets, odd channels at the following odd byte). The cascade (16-bit) address is the even-channel base; 16-bit bus accesses at those addresses transfer the even channel as the upper 8 bits and the odd channel as the lower 8.

Note

Manual: Ch30.1.1 Table 30.1 - TMR Base Address Map

00557 } rx_tmr_mstpcra_t;

```

8.63.3.5 rx_tmr_tccr_bits_t

```
enum rx_tmr_tccr_bits_t : uint8_t
```

TCCR bit positions.

Bit Layout (8-bit)

Bits	Field	R/W	Description
7	TMRIS	R/W	External reset detection (0=edge, 1=level)
6↔ 5	-	R/W	Reserved (write 0)
4↔ 3	CSS[1:↔ 0]	R/W	Clock source select
2↔ 0	CKS[2:↔ 0]	R/W	Clock divider select

Note

Manual: Ch30.2.5 - Timer Counter Control Register (TCCR)

Since

Version 1.0.0

Enumerator

k_tmr_tccr_tmris	Timer reset detection condition
------------------	---------------------------------

Definition at line 418 of file rx72n_tmr_regs.h.

```
00418     : uint8_t {
00419   k_tmr_tccr_tmris = (1U « 7), /**< Timer reset detection condition */
00420 } rx_tmr_tccr_bits_t;
```

8.63.3.6 rx_tmr_tccr_cks_external_t

```
enum rx_tmr_tccr_cks_external_t : uint8_t
```

TCCR CKS[2:0] edge selection when CSS = external clock.

External Edge Selection (Table 30.5)

CKS	Edge
000b	Clock prohibited

CKS	Edge
001b	Count at rising edge
010b	Count at falling edge
011b	Count at both rising and falling

Since

Version 1.0.0

Enumerator

k_tmr_tccr_cks_ext_rising	001b: rising-edge count
k_tmr_tccr_cks_ext_falling	010b: falling-edge count
k_tmr_tccr_cks_ext_both	011b: both-edge count

Definition at line 508 of file [rx72n_tmr_regs.h](#).

```

00508      : uint8_t {
00509  k_tmr_tccr_cks_ext_rising = 0x1, /**< 001b: rising-edge count      */
00510  k_tmr_tccr_cks_ext_falling = 0x2, /**< 010b: falling-edge count   */
00511  k_tmr_tccr_cks_ext_both   = 0x3, /**< 011b: both-edge count     */
00512 } rx_tmr_tccr_cks_external_t;
```

8.63.3.7 rx_tmr_tccr_cks_internal_t

enum [rx_tmr_tccr_cks_internal_t](#) : uint8_t

TCCR CKS[2:0] divider values when CSS = internal clock.

Internal Clock Dividers (Table 30.5)

CKS	Source
000b	Clock prohibited
001b	PCLK
010b	PCLK/ $\leftarrow$ 2
011b	PCLK/ $\leftarrow$ 8
100b	PCLK/32
101b	PCLK/64
110b	PCLK/1024
111b	PCLK/8192

Note

Manual table order differs from register encoding. Values below match the exact bit pattern written to CKS[2:0].

Since

Version 1.0.0

Enumerator

k_tmr_tccr_cks_prohibited	000b: clock input prohibited
k_tmr_tccr_cks_pclk_div1	001b: PCLK / 1
k_tmr_tccr_cks_pclk_div2	010b: PCLK / 2
k_tmr_tccr_cks_pclk_div8	011b: PCLK / 8
k_tmr_tccr_cks_pclk_div32	100b: PCLK / 32
k_tmr_tccr_cks_pclk_div64	101b: PCLK / 64
k_tmr_tccr_cks_pclk_div1024	110b: PCLK / 1024
k_tmr_tccr_cks_pclk_div8192	111b: PCLK / 8192

Definition at line 483 of file [rx72n_tmr_regs.h](#).

```

00491  k_tmr_tccr_cks_pclk_div8192 = 0x7, /**< 111b: PCLK / 8192        */
00492 } rx_tmr_tccr_cks_internal_t;

```

8.63.3.8 rx_tmr_tccr_css_t

```
enum rx\_tmr\_tccr\_css\_t : uint8_t
```

TCCR CSS[1:0] clock source select (per Table 30.5).

Source Meaning

Value	Channel	Source
00b	any	External count clock on TMCI pin (edge selected by CKS)
01b	any	Internal clock (PCLK divider selected by CKS)
10b	any	Setting prohibited
11b	TMR0/ 2	Count on odd-channel TCNT overflow (cascade lower->up)
11b	TMR1/ 3	Count on even-channel TCORA compare match (cascade)

Since

Version 1.0.0

Enumerator

k_tmr_tccr_css_external	External count clock on TMCI pin
k_tmr_tccr_css_internal	Internal PCLK source (use CKS)
k_tmr_tccr_css_cascade	Cascade from paired channel

Definition at line 457 of file [rx72n_tmr_regs.h](#).

```
00457      : uint8_t {
00458  k_tmr_tccr_css_external = (0U « 3), /**< External count clock on TMCI pin */

00430 } rx_tmr_tccr_shift_t;
```

8.63.3.11 rx_tmr_tcr_bits_t

enum rx_tmr_tcr_bits_t : uint8_t

TCR bit positions and single-bit masks.

Bit Layout (8-bit)

Bits	Field	R/W	Description
7	CMIEB	R/W	TCORB compare match interrupt enable
6	CMIEA	R/W	TCORA compare match interrupt enable
5	OVIE	R/W	TCNT overflow interrupt enable
4:↔ 3	CCLR[1:↔ 0]	R/W	Counter clear source select
2:↔ 0	-	R/W	Reserved (must be written 0)

Note

Manual: Ch30.2.4 - Timer Control Register (TCR)

Since

Version 1.0.0

Enumerator

k_tmr_tcr_cmieb	TCORB compare match interrupt enable
k_tmr_tcr_cmiea	TCORA compare match interrupt enable
k_tmr_tcr_ovie	Overflow interrupt enable

Definition at line 306 of file rx72n_tmr_regs.h.

```
00306      : uint8_t {
00307  k_tmr_tcr_cmieb = (1U « 7), /**< TCORB compare match interrupt enable */
00308  k_tmr_tcr_cmiea = (1U « 6), /**< TCORA compare match interrupt enable */
00309  k_tmr_tcr_ovie  = (1U « 5), /**< Overflow interrupt enable */
00310 } rx_tmr_tcr_bits_t;
```

8.63.3.12 rx_tmr_tcr_cclr_t

```
enum rx_tmr_tcr_cclr_t : uint8_t
```

TCR CCLR[1:0] counter clear source.

Note

Manual: Ch30.2.4 Table - CCLR field

Since

Version 1.0.0

Enumerator

k_tmr_tcr_cclr_disabled	00b: Counter clear disabled
k_tmr_tcr_cclr_cmp_match_a	01b: Clear on TCORA match
k_tmr_tcr_cclr_cmp_match_b	10b: Clear on TCORB match
k_tmr_tcr_cclr_external_sig	11b: Clear on external reset

Definition at line 319 of file [rx72n_tmr_regs.h](#).

```
00319 : uint8_t {
00320 k_tmr_tcr_cclr_disabled = (0U « 3), /**< 00b: Counter clear disabled */

00322 k_tmr_tcr_cclr_cmp_match_b = (2U « 3), /**< 10b: Clear on TCORB match */
00323 k_tmr_tcr_cclr_external_sig = (3U « 3), /**< 11b: Clear on external reset */
00324 } rx_tmr_tcr_cclr_t;
```

8.63.3.13 rx_tmr_tcr_masks_t

```
enum rx_tmr_tcr_masks_t : uint8_t
```

TCR register field masks.

Since

Version 1.0.0

Enumerator

k_tmr_tcr_cclr_mask	CCLR[1:0] field mask (bits 4:3)
---------------------	---------------------------------

Definition at line 331 of file [rx72n_tmr_regs.h](#).

```
00331 : uint8_t {
00332 k_tmr_tcr_cclr_mask = 0x18, /**< CCLR[1:0] field mask (bits 4:3) */
00333 } rx_tmr_tcr_masks_t;
```

8.63.3.14 rx_tmr_tcsr_bits_t

```
enum rx_tmr_tcsr_bits_t : uint8_t
```

TCSR bit positions (even channels TMR0/TMR2).

Bit Layout (8-bit, even channels)

Bits	Field	R/W	Description
7↔ 5	-	R	Undefined at reset
4	ADTE	R/W	A/D trigger enable (TMR0/TMR2 only)
3↔ 2	OSB[1↔ 0]	R/W	TMO output select on TCORB compare match
1↔ 0	OSA[1↔ 0]	R/W	TMO output select on TCORA compare match

Note

For odd channels (TMR1/TMR3), bit 4 is reserved and reads as 1.

Manual: Ch30.2.6 - Timer Control/Status Register (TCSR)

Since

Version 1.0.0

Enumerator

k_tmr_tcsr_adte	A/D trigger enable (even channels only)
-----------------	---

Definition at line 356 of file rx72n_tmr_regs.h.

```
00356         : uint8_t {
00357   k_tmr_tcsr_adte = (1U « 4), /**< A/D trigger enable (even channels only) */
00358 } rx_tmr_tcsr_bits_t;
```

8.63.3.15 rx_tmr_tcsr_masks_t

```
enum rx_tmr_tcsr_masks_t : uint8_t
```

TCSR field masks.

Since

Version 1.0.0

Enumerator

k_tmr_tcsr_osa_mask	OSA[1:0] field mask (bits 1:0)
k_tmr_tcsr_osb_mask	OSB[1:0] field mask (bits 3:2)
k_tmr_tcsr_odd_reserved	Odd-channel bit 4 reserved, reads as 1

Definition at line 392 of file [rx72n_tmr_regs.h](#).

```
00392      : uint8_t {
00393  k_tmr_tcsr_osa_mask    = 0x03, /**< OSA[1:0] field mask (bits 1:0) */
00394  k_tmr_tcsr_osb_mask    = 0x0C, /**< OSB[1:0] field mask (bits 3:2) */
00395  k_tmr_tcsr_odd_reserved = 0x10, /**< Odd-channel bit 4 reserved, reads as 1 */
00396 } rx_tmr_tcsr_masks_t;
```

8.63.3.16 rx_tmr_tcsr_output_t

```
enum rx_tmr_tcsr_output_t : uint8_t
```

TCSR OSA/OSB output select values (identical encoding).

Controls the TMO pin behavior on compare match. Both OSA and OSB use this 2-bit encoding; shift the value left by 0 for OSA and 2 for OSB.

Since

Version 1.0.0

Enumerator

k_tmr_tcsr_output_no_change	00b: No change
k_tmr_tcsr_output_low	01b: Drive low on compare match
k_tmr_tcsr_output_high	10b: Drive high on compare match
k_tmr_tcsr_output_toggle	11b: Toggle on compare match

Definition at line 370 of file [rx72n_tmr_regs.h](#).

```
00370      : uint8_t {
00371  k_tmr_tcsr_output_no_change = 0x0, /**< 00b: No change */
00372  k_tmr_tcsr_output_low      = 0x1, /**< 01b: Drive low on compare match */
00373  k_tmr_tcsr_output_high     = 0x2, /**< 10b: Drive high on compare match */
00374  k_tmr_tcsr_output_toggle   = 0x3, /**< 11b: Toggle on compare match */
00375 } rx_tmr_tcsr_output_t;
```

8.63.3.17 rx_tmr_tcsr_shift_t

```
enum rx_tmr_tcsr_shift_t : uint8_t
```

TCSR output-select field shifts.

Since

Version 1.0.0

Enumerator

k_tmr_tcsr_osa_shift	OSA[1:0] starts at bit 0
k_tmr_tcsr_osb_shift	OSB[1:0] starts at bit 2

Definition at line 382 of file [rx72n_tmr_regs.h](#).

```
00382      : uint8_t {
00383  k_tmr_tcsr_osa_shift = 0, /**< OSA[1:0] starts at bit 0 */

00385 } rx_tmr_tcsr_shift_t;
```

8.63.3.18 rx_tmr_tcsr_bits_t

```
enum rx_tmr_tcsr_bits_t : uint8_t
```

TCSTR bit positions.

Bit Layout (8-bit)

Bits	Field	R/W	Description
7:1	-	R/W	Reserved
0	TCS	R/W	Count state from ELC (0=stopped, 1=running)

Note

Manual: Ch30.2.7 - Timer Counter Start Register (TCSTR)

TCS is only valid when ELC event controller drives the channel; software should write 0 to stop and leave 1 for ELC to set.

Since

Version 1.0.0

Enumerator

k_tmr_tcsr_tcs	Timer counter status (ELC)
----------------	----------------------------

Definition at line 534 of file [rx72n_tmr_regs.h](#).

```
00534      : uint8_t {
00535  k_tmr_tcsr_tcs = (1U << 0), /**< Timer counter status (ELC) */
00536 } rx_tmr_tcsr_bits_t;
```

8.63.4 Function Documentation

8.63.4.1 tmr0()

```
volatile rx_tmr_channel_regs_t * tmr0 (
    void ) [inline], [static]
```

Get pointer to TMR0 channel register block (unit 0 even channel).

Returns

Volatile pointer to TMR0 register block at 0x00088200

Precondition

TMR unit 0 module clock enabled (MSTPCRA.MSTPA5 = 0)

Postcondition

Returned pointer is valid for the lifetime of the program

Note

Thread Safety: Safe - returns a constant hardware address

See also

[k_tmr0_base_addr](#)

Since

Version 1.0.0

Definition at line 211 of file [rx72n_tmr_regs.h](#).

8.63.4.2 tmr01_cascade()

```
volatile rx\_tmr\_cascade\_regs\_t * tmr01_cascade (  
    void )    [inline], [static]
```

Get pointer to TMR01 cascaded 16-bit register view.

Returns

Volatile pointer to TMR01 cascade block at 0x00088200

Precondition

TMR unit 0 module clock enabled

Cascade mode configured via TMR1.TCCR (CSS/CKS = overflow of TMR0)

Postcondition

Returned pointer is valid for the lifetime of the program

Note

Thread Safety: Safe - returns a constant hardware address

Since

Version 1.0.0

Definition at line 267 of file [rx72n_tmr_regs.h](#).

00003  * @brief RX72N 8-Bit Timer (TMRb) Register Definitions
00004  *
00005  * @details
00006  * Register definitions for the TMR peripheral which provides 4 channels of
00007  * 8-bit timers (TMR0..TMR3) organized into two units. Each unit contains two
00008  * channels that may operate independently (two 8-bit counters) or cascaded
00009  * (one 16-bit counter, TMR01 or TMR23).
00010  *
00011  * @par Channel and Unit Layout
00012  * | Unit | Channels | Module Stop Bit | Cascade Name |
00013  * |-----|-----|-----|-----|
00014  * | 0 | TMR0, TMR1 | MSTPCRA.MSTPA5 | TMR01 |
```

```

00015 * | 1 | TMR2, TMR3 | MSTPCRA.MSTPA4 | TMR23 |
00016 *
00017 * @par Key Features
00018 * - 8-bit up-counter with two compare-match registers (TCORA, TCORB)
00019 * - Optional 16-bit cascaded mode (even + odd channel concatenated)
00020 * - Counter clear on compare match A, compare match B, or external reset
00021 * - 8 clock sources per channel (external edge/level, PCLK dividers, cascade)
00022 * - Compare match A/B and overflow interrupts via SELECTB
00023 * - Dedicated TMO output pin per channel for hardware pulse generation
00024 *
00025 * @par Register Map Overview (Unit 0 / Unit 1)
00026 * | Even Ch Addr | Odd Ch Addr | Register | Size | Description |
00027 * |-----|-----|-----|-----|-----|
00028 * | 0x00088200 | 0x00088201 | TCR | 8 | Timer Control |
00029 * | 0x00088202 | 0x00088203 | TCSR | 8 | Timer Control/Status |
00030 * | 0x00088204 | 0x00088205 | TCORA | 8 | Time Constant A |
00031 * | 0x00088206 | 0x00088207 | TCORB | 8 | Time Constant B |
00032 * | 0x00088208 | 0x00088209 | TCNT | 8 | Timer Counter |
00033 * | 0x0008820A | 0x0008820B | TCCR | 8 | Timer Counter Control |
00034 * | 0x0008820C | 0x0008820D | TCSTR | 8 | Timer Counter Start (ELC) |
00035 *
00036 * Unit 1 uses the same layout offset +0x10 (TMR2 base 0x00088210, TMR3 0x00088211).
00037 *
00038 * @par NASA Power of 10 Compliance
00039 * - Rule 1: No goto, setjmp, or recursion
00040 * - Rule 2: N/A (no loops in register definitions)
00041 * - Rule 3: No dynamic memory allocation
00042 * - Rule 4: All accessor functions are single-statement
00043 * - Rule 5: N/A (hardware layer)
00044 * - Rule 6: Minimal scope - inline accessors only
00045 * - Rule 7: N/A (no return values to check)
00046 * - Rule 8: All constants use C23 typed enums
00047 * - Rule 9: No function pointers
00048 * - Rule 10: Compiles with -Wall -Wextra -Werror
00049 *

00123  * @struct rx_tmr_channel_regs_t
00124  * @brief TMR single-channel register block
00125  *
00126  * @details
00127  * Register block for one TMR channel accessed via byte strides of 2. Because
00128  * even and odd channels share the same 16-byte block at different parity
00129  * offsets, accessing TMRn directly requires striding by 2 bytes per field;
00130  * this structure therefore represents ONE channel with the interleaved odd
00131  * byte reserved.
00132  *
00133  * The layout follows the byte addressing in Table 30.1:
00134  * - TMR0.TCR @ 0x88200, TMR1.TCR @ 0x88201
00135  * - TMR0.TCSR @ 0x88202, TMR1.TCSR @ 0x88203
00136  * - TMR0.TCOR @ 0x88204, TMR1.TCOR @ 0x88205
00137  * - TMR0.TCORB @ 0x88206, TMR1.TCORB @ 0x88207
00138  * - TMR0.TCNT @ 0x88208, TMR1.TCNT @ 0x88209
00139  * - TMR0.TCCR @ 0x8820A, TMR1.TCCR @ 0x8820B
00140  * - TMR0.TCSTR @ 0x8820C, TMR1.TCSTR @ 0x8820D
00141  *
00142  * Pointer returned by tmr0()/tmr2() points to the even byte; pointer returned
00143  * by tmr1()/tmr3() points to the odd byte. Each struct field therefore
00144  * accesses the channel's own byte.
00145  *
00146  * @invariant sizeof(rx_tmr_channel_regs_t) == 14 (spans byte 0 through 12)

`k_tpu_intb_tci5v` = 39 , `k_tpu_intb_tci5u` = 40 }

TPU Software Configurable Interrupt B source numbers.

Functions

- static volatile `rx_tpu_control_regs_t` * `tpu_control` (void)
 Get pointer to TPU control block registers.
- static volatile `rx_tpu_ext_regs_t` * `tpu0` (void)
 Get pointer to TPU0 channel registers (extended).
- static volatile `rx_tpu_regs_t` * `tpu1` (void)
 Get pointer to TPU1 channel registers (basic, phase counting).
- static volatile `rx_tpu_regs_t` * `tpu2` (void)
 Get pointer to TPU2 channel registers (basic, phase counting).
- static volatile `rx_tpu_ext_regs_t` * `tpu3` (void)
 Get pointer to TPU3 channel registers (extended).
- static volatile `rx_tpu_regs_t` * `tpu4` (void)
 Get pointer to TPU4 channel registers (basic, phase counting).
- static volatile `rx_tpu_regs_t` * `tpu5` (void)
 Get pointer to TPU5 channel registers (basic, phase counting).

8.65.1 Detailed Description

RX72N 16-Bit Timer Pulse Unit (TPU) Register Definitions.

Register definitions for the TPU module which provides 6 channels of 16-bit timers with quadrature encoder phase counting capability. In STAR, the TPU is used for rear wheel encoder decoding via hardware phase counting mode.

STAR Project Quadrature Encoder System

TPU Channel Assignments in STAR

Channel	Type	Use in STAR	Phase Count	Clock Pins
TPU0	Extended	Not used	No	-
TPU1	Basic	Back-right encoder	Yes (mode 4)	TCLKA + TCLKB
TPU2	Basic	Back-left encoder	Yes (mode 4)	TCLKC + TCLKD
TPU3	Extended	Not used	No	-
TPU4	Basic	Not used (paired 2)	Yes	TCLKC + TCLKD
TPU5	Basic	Not used (paired 1)	Yes	TCLKA + TCLKB

Phase Counting Mode 4 (4x Resolution)

Counts on all edges of both A-phase and B-phase inputs, providing 4x the base encoder resolution.
 For 341 PPR encoders: $341 * 4 = 1364$ counts/rev.

A-Phase Edge	B-Phase Level	Direction
Rising	Low	Up
Rising	High	Down
Falling	Low	Down
Falling	High	Up

| (same for B-phase edges with A-phase level swapped) |

Key Features

- 6 channels of 16-bit timers (TPU0-TPU5)
- Hardware quadrature phase counting on TPU1/2/4/5
- 4 phase counting modes (1x, 2x, 3x, 4x resolution)
- TSR.TCFD direction flag for up/down detection
- Overflow/underflow interrupt support
- Noise filter on I/O pins
- Synchronous operation between channels

Hardware Requirements

Parameter	Value	Notes
Control Base	0x00088100	TSTR, TSYR, NFCR registers
Channel Spacing	0x10 bytes	TPU0=0x110, TPU1=0x120, etc.
Module Stop	MSTPCRA.MSTPA13	0=run, 1=stop
Clock	PCLKB (60 MHz)	For noise filter and prescaler

Register Map Overview

Address	Register	Size	Description
0x00088100	TSTR	8	Timer Start Register
0x00088101	TSYR	8	Timer Synchronous Register
0x00088108-0D	NFCRn	8x6	Noise Filter Control (0-5)
0x00088110-1F	TPU0 registers	16	Extended channel (4 TGR)
0x00088120-2F	TPU1 registers	16	Basic channel (2 TGR)
0x00088130-3F	TPU2 registers	16	Basic channel (2 TGR)
0x00088140-4F	TPU3 registers	16	Extended channel (4 TGR)
0x00088150-5F	TPU4 registers	16	Basic channel (2 TGR)
0x00088160-6F	TPU5 registers	16	Basic channel (2 TGR)

NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: N/A (no loops in register definitions)
- Rule 3: No dynamic memory allocation
- Rule 4: All accessor functions are single-statement
- Rule 5: N/A (hardware layer)
- Rule 6: Minimal scope - inline accessors only
- Rule 7: N/A (no return values to check)
- Rule 8: All constants use C23 typed enums
- Rule 9: No function pointers
- Rule 10: Compiles with -Wall -Wextra -Werror

SOLID Principles

- S: Single responsibility - only TPU register definitions
- O: Open for extension via additional channel configurations
- L: N/A (no inheritance hierarchy)
- I: Minimal interface - only necessary accessor functions
- D: N/A (hardware register layer)

Module Dependencies

- `<stdint.h>` - Fixed-width integer types
- `<stddef.h>` - `offsetof` macro for static assertions

8.65.2.1 struct rx_tpu_control_regs_t

TPU Control Block Register Structure.

Contains the shared control registers for all TPU channels: the Timer Start Register (TSTR), Timer Synchronous Register (TSYR), and per-channel Noise Filter Control Registers (NFCR).

Memory Layout Table

Offset	Size	Field	Type	Description
0x00	1	tstr	uint8↔ _t	Timer Start Register
0x01	1	tsyr	uint8↔ _t	Timer Synchronous Register
0x02	6	reserved	uint8↔ t[]	Reserved
0x08	6	nfcrl [0..5]	uint8↔ t[]	Noise Filter Control (per ch)
Total	14			

Invariant

```
sizeof(rx_tpu_control_regs_t) == 14 bytes
```

8.65.2.2 struct rx_tpu_ext_regs_t

TPU Extended Channel Register Structure (TPU0 and TPU3).

Register layout for TPU0 and TPU3 which have two I/O control registers (TIORH + TIORL) and four timer general registers (TGRA through TGRD). These channels do NOT support phase counting mode.

Memory Layout Table

Offset	Size	Field	Type	Description
0x00	1	tcr	uint8↔ _t	Timer Control Register
0x01	1	tmdr	uint8↔ _t	Timer Mode Register
0x02	1	tiorh	uint8↔ _t	Timer I/O Control Register H
0x03	1	tiorl	uint8↔ _t	Timer I/O Control Register L
0x04	1	tier	uint8↔ _t	Timer Interrupt Enable Register
0x05	1	tsr	uint8↔ _t	Timer Status Register
0x06	2	tcnt	uint16↔ _t	Timer Counter
0x08	2	tgra	uint16↔ _t	Timer General Register A

Offset	Size	Field	Type	Description
0x0A	2	tgrb	uint16↔ _t	Timer General Register B
0x0C	2	tgrc	uint16↔ _t	Timer General Register C
0x0E	2	tgrd	uint16↔ _t	Timer General Register D
Total	16			

Invariant

```
sizeof(rx_tpu_ext_regs_t) == 16 bytes
```

Note

TPU0 and TPU3 do NOT support phase counting mode

Buffer operation available: TGRA+TGRC and TGRB+TGRD pairs

Invariant

`sizeof(rx_tpu_regs_t) == 16 bytes`

Phase Counting Mode Usage

```
// Configure TPU1 for phase counting mode 4 (4x resolution)
volatile rx_tpu_regs_t* ch = tpu1();

// 1. Stop counter first
tpu_control()->tstr &= (uint8_t)~k_tpu_tstr_cst1;

// 2. Set phase counting mode 4 in TMDR
ch->tmdr = k_tpu_tmdr_md_phase_count_4;

// 3. Start counter
tpu_control()->tstr |= k_tpu_tstr_cst1;

// 4. Read counter and direction
uint16_t count = ch->tcnt;
bool counting_up = (ch->tsr & k_tpu_tsr_tcfid) != 0;
```

8.65.3 Enumeration Type Documentation

8.65.3.1 rx'tpu'addresses't

```
enum rx_tpu_addresses_t : uintptr_t
```

TPU base addresses.

Base addresses for the TPU control block and individual channel register blocks. The control block contains TSTR, TSYR, and NFCR registers shared across all channels. Each channel has a 16-byte register block.

Memory Map

Address	Block	Description
0x00088100	Control	TSTR, TSYR, NFCR (shared across channels)
0x00088110	TPU0	Extended channel (TIORH/L, TGRA-TGRD)
0x00088120	TPU1	Basic channel (TIOR, TGRA-TGRB)
0x00088130	TPU2	Basic channel (TIOR, TGRA-TGRB)
0x00088140	TPU3	Extended channel (TIORH/L, TGRA-TGRD)
0x00088150	TPU4	Basic channel (TIOR, TGRA-TGRB)
0x00088160	TPU5	Basic channel (TIOR, TGRA-TGRB)

```

8.65.3.2 rx'tpu'channel'count't

```
enum rx_tpu_channel_count_t : uint8_t
```

TPU channel count constant.

Since

Version 1.0.0

Enumerator

k_tpu_channel_count	Total TPU channels (TPU0-TPU5)
---------------------	--------------------------------

Definition at line 254 of file [rx72n_tpu_regs.h](#).

```
00254      : uint8_t {
00255 k_tpu_channel_count = 6, /**< Total TPU channels (TPU0-TPU5) */
00256 } rx_tpu_channel_count_t;
```

8.65.3.3 rx'tpu'intb'source't

```
enum rx_tpu_intb_source_t : uint8_t
```

TPU Software Configurable Interrupt B source numbers.

TPU interrupts are routed through the ICU Software Configurable Interrupt B mechanism. These source numbers are written to SLIBRn registers (n=128-207) to map them to interrupt vector numbers 128-207.

For phase counting mode, the most relevant sources are:

- TCIXV (overflow): TCNT wrapped 0xFFFF -> 0x0000 while counting up
- TCIXU (underflow): TCNT wrapped 0x0000 -> 0xFFFF while counting down

Configuration Example

```
// Map TPU1 overflow to vector 128 (INTB128)
ICU.SLIBR128.BYTE = k_tpu_intb_tci1v;
// Map TPU1 underflow to vector 129 (INTB129)
ICU.SLIBR129.BYTE = k_tpu_intb_tci1u;
```

Note

Manual: Ch15 Table 15.3 - Interrupt Sources for Software Configurable Interrupt B, and Ch28.4 - Interrupt Sources

Warning

These are NOT vector numbers - they are source numbers for SLIBR

Since

Version 1.0.0

```

TSR (Timer Status Register) bit definitions.

Status flags for timer events and counting direction. The TCFD flag is critical for phase counting mode - it indicates whether TCNT is currently counting up (forward) or down (reverse).

Bit Layout (8-bit)

Bit	Field	Description
0	TGFA	TGRA compare match/input capture flag
1	TGFB	TGRB compare match/input capture flag
2	TGFC	TGRC compare match/input capture (0,3)
3	TGFD	TGRD compare match/input capture (0,3)
4	TCFV	Overflow flag (all channels)
5	TCFU	Underflow flag (TPU1/2/4/5 only)
6	-	Reserved (read as 1, write 1)
7	TCFD	Counting Direction Flag (TPU1/2/4/5)

Note

Flags (bits 0-5) are cleared by writing 0 to them

TCFD is read-only: 1=counting up, 0=counting down

Bit 6 reset value is 1 (must write 1 to preserve)

TGFC/TGFD reserved on TPU1/2/4/5 (read as 0, write 0)

TCFU/TCFD reserved on TPU0/TPU3 (read as 0/1 respectively)

```

8.65.4 Function Documentation

8.65.4.1 tpu0()

```
volatile rx_tpu_ext_regs_t * tpu0 (
    void ) [inline], [static]
```

Get pointer to TPU0 channel registers (extended).

Returns a volatile pointer to TPU0 extended channel registers at address 0x00088110. TPU0 has TIORH/TIORL and TGRA through TGRD.

Returns

Volatile pointer to TPU0 extended register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

TPU module enabled (MSTPCRA.MSTPA13 = 0)

Postcondition

Pointer valid for lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

TPU0 does NOT support phase counting mode

See also

[k_tpu0_base_addr](#) Base address constant

Since

Version 1.0.0

Definition at line 528 of file [rx72n_tpu_regs.h](#).

```

00530     return (volatile rx_tpu_ext_regs_t*)k_tpu0_base_addr;
00531 }
```

References [k_tpu0_base_addr](#).

8.65.4.2 tpu1()

```
volatile rx_tpu_regs_t * tpu1 (
    void )    [inline], [static]
```

Get pointer to TPU1 channel registers (basic, phase counting).

Returns a volatile pointer to TPU1 basic channel registers at address 0x00088120. TPU1 supports phase counting mode using TCLKA (A-phase) and TCLKB (B-phase) external clock pins. Used for back-right encoder.

Returns

Volatile pointer to TPU1 register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

TPU module enabled (MSTPCRA.MSTPA13 = 0)

Postcondition

Pointer valid for lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

Example:

```
// Read back-right encoder count and direction
uint16_t count = tpu1()->tcnt;
bool forward = (tpu1()->tsr & k_tpu_tsr_tcfld) != 0;
```

8.65.4.3 tpu2()

```
volatile rx_tpu_regs_t * tpu2 (
    void )    [inline], [static]
```

Get pointer to TPU2 channel registers (basic, phase counting).

Returns a volatile pointer to TPU2 basic channel registers at address 0x00088130. TPU2 supports phase counting mode using TCLKC (A-phase) and TCLKD (B-phase) external clock pins. Used for back-left encoder.

Returns

Volatile pointer to TPU2 register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

TPU module enabled (MSTPCRA.MSTPA13 = 0)

Postcondition

Pointer valid for lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

Here is the caller graph for this function:

8.65.4.4 tpu3()

```
volatile rx_tpu_ext_regs_t * tpu3 (
    void )    [inline], [static]
```

Get pointer to TPU3 channel registers (extended).

Returns a volatile pointer to TPU3 extended channel registers at address 0x00088140. TPU3 has TIORH/TIORL and TGRA through TGRD.

Returns

Volatile pointer to TPU3 extended register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

TPU module enabled (MSTPCRA.MSTPA13 = 0)

Postcondition

Pointer valid for lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address
TPU3 does NOT support phase counting mode

8.65.4.5 tpu4()

```
volatile rx_tpu_regs_t * tpu4 (
    void )    [inline], [static]
```

Get pointer to TPU4 channel registers (basic, phase counting).

Returns a volatile pointer to TPU4 basic channel registers at address 0x00088150. TPU4 supports phase counting mode using TCLKC/TCLKD pins (paired with TPU2).

Returns

Volatile pointer to TPU4 register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

TPU module enabled (MSTPCRA.MSTPA13 = 0)

Postcondition

Pointer valid for lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

8.65.4.6 tpu5()

```
volatile rx_tpu_regs_t * tpu5 (
    void ) [inline], [static]
```

Get pointer to TPU5 channel registers (basic, phase counting).

Returns a volatile pointer to TPU5 basic channel registers at address 0x00088160. TPU5 supports phase counting mode using TCLKA/TCLKB pins (paired with TPU1).

Returns

Volatile pointer to TPU5 register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

TPU module enabled (MSTPCRA.MSTPA13 = 0)

Postcondition

Pointer valid for lifetime of program execution

8.65.4.7 tpu_control()

```
volatile rx_tpu_control_regs_t * tpu_control (
    void )    [inline], [static]
```

Get pointer to TPU control block registers.

Returns a volatile pointer to the TPU control register block at address 0x00088100. Contains TSTR (timer start), TSYR (synchronous), and NFCR (noise filter) registers shared across all channels.

Returns

Volatile pointer to TPU control register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

TPU module enabled (MSTPCRA.MSTPA13 = 0)

Postcondition

Pointer valid for lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

Example:

```
// Start TPU1 and TPU2 counters simultaneously  
tpu_control()->tstr |= (k_tpu_tstr_cst1 | k_tpu_tstr_cst2);
```

Functions

- static volatile `rx_usb_regs_t` * `usb0` (void)
- static volatile `uint32_t` * `usb_dpusr0r` (void)

Get pointer to USB deep-standby transceiver control register (DPUSR0R), 32-bit, at absolute 0x000A0400.

8.67.1 Detailed Description

RX72N USB 2.0 Full-Speed Host/Function Module Register Definitions.

Register definitions for the USB 2.0 Full-Speed Host/Function Module (USB0) verified against RX72N Group User's Manual: Hardware (R01UH0824EJ0111), Chapter 40 "USB 2.0 FS Host/Function Module (USBb)".

Verification Status (2026-04-20):

- All register addresses verified against manual Chapter 40
- 45 registers defined with correct offsets
- 55+ static assertions verify all offsets at compile time
- Removed non-existent registers (BUSWAIT, PLLSTA, TESTMODE, D0FBCFG, D1FBCFG, PHYSET, PIPEBUF, LPCTRL, LPSTS - these do NOT exist on RX72N)
- Renamed UFRMNUM to DVCHGR (correct register name per manual)
- CRITICAL FIX (2026-02-03): Changed FIFO registers from uint32_t to uint16_t per manual Ch40 p.1941. CFIFO/D0FIFO/D1FIFO are 16-bit WORD registers, NOT 32-bit. Added padding to maintain correct struct offsets.
- FIX (2026-04-20): Added missing DVSTCTR0 bits VBUSEN(b9), EXICEN(b10), HNPBTOA(b11) per manual p.1940.
- FIX (2026-04-20): Split usb_fifo_sel_bits_t into [usb_cfifosel_bits_t](#) and [usb_dnfifosel_bits_t](#). CFIFOSEL has ISEL(b5) but NOT DREQE/DCLRM. D0/D1FIFOSEL have DREQE(b12)/↔ DCLRM(b13) but NOT ISEL. Per manual p.1942-1944.

8.67.2 Data Structure Documentation

8.67.2.1 struct rx_usb_regs_t

USB0 Register Map (Base: 0x000A0000).

Note

The following registers do NOT exist on RX72N (removed from struct): BUSWAIT, PLLSTA, TESTMODE, D0FBCFG, D1FBCFG, PHYSET, PIPEBUF, LPCTRL, LPSTS

FIFO registers (CFIFO, D0FIFO, D1FIFO) are 16-bit WORD registers per manual Ch40 p.1941. Access width controlled by CFIFOSEL.MBW/D0FIFOSEL.MBW:

- MBW=1 ([k_usb_cfifosel_mbw_16](#)): 16-bit word access (b15-b0)
- MBW=0 ([k_usb_cfifosel_mbw_8](#)): 8-bit byte access (b7-b0)

8.67.3 Enumeration Type Documentation

8.67.3.1 rx'usb'addresses't

```
enum rx_usb_addresses_t : uintptr_t
```

USB0 peripheral base address (verified against RX72N Hardware Manual Ch40).

Memory-mapped base address for the USB 2.0 Full-Speed Host/Function Module (USB0). Cast to a volatile pointer via `usb0()` to access the register map.

The underlying type is `uintptr_t` to correctly express that this value is a memory address, not a plain integer. On RX72N (32-bit) `uintptr_t == uint32_t`, so there is no runtime difference.

Memory Layout

```

*   Address      | Peripheral
*   -----+-----
*   0x000A0000   | USB0 register block (see rx_usb_regs_t)
*
```

```
00001 /**
00002  * @file rx72n_usb_regs.h
00003  * @brief RX72N USB 2.0 Full-Speed Host/Function Module Register Definitions
00004  *
00005  * @details
00006  * Register definitions for the USB 2.0 Full-Speed Host/Function Module (USB0)
00007  * verified against RX72N Group User's Manual: Hardware (R01UH0824EJ0111),
00008  * Chapter 40 "USB 2.0 FS Host/Function Module (USBb)".
00009  *
00010  * @par Verification Status (2026-04-20):
00011  * - All register addresses verified against manual Chapter 40
00012  * - 45 registers defined with correct offsets
00013  * - 55+ static assertions verify all offsets at compile time
00014  * - Removed non-existent registers (BUSWAIT, PLLSTA, TESTMODE, D0FBCFG,
00015  *   D1FBCFG, PHYSET, PIPEBUF, LPCTRL, LPSTS - these do NOT exist on RX72N)
00016  * - Renamed UFRMNUM to DVCHGR (correct register name per manual)
00017  * - CRITICAL FIX (2026-02-03): Changed FIFO registers from uint32_t to uint16_t
```

```

00018 * per manual Ch40 p.1941. CFIFO/D0FIFO/D1FIFO are 16-bit WORD registers,
00019 * NOT 32-bit. Added padding to maintain correct struct offsets.
00020 * - FIX (2026-04-20): Added missing DVSTCTR0 bits VBUSEN(b9), EXICEN(b10),
00021 * HNPBTOA(b11) per manual p.1940.
00022 * - FIX (2026-04-20): Split usb_fifoel_bits_t into usb_cffosel_bits_t and
00023 * usb_dnfifosel_bits_t. CFIFOSEL has ISEL(b5) but NOT DREQE/DCLRM.
00024 * D0/D1FIFOSEL have DREQE(b12)/DCLRM(b13) but NOT ISEL. Per manual p.1942-1944.
00025 *

- static volatile [rx_wdt_regs_t](#) * [wdt](#) (void)
Get pointer to WDT registers.

8.69.1 Detailed Description

RX72N WDT Watchdog Timer Register Definitions.

Register definitions for the Watchdog Timer (WDT) module on the RX72N microcontroller. The WDT provides system monitoring to detect software runaway conditions and reset the system if necessary.

System Architecture

WDT vs IWDTC Comparison

Feature	WDT (This Module)	IWDTC
Clock Source	PCLKB (60 MHz)	Dedicated 120 kHz
Stop in Software	Yes	No (once started)
Debug/Sleep Ctrl	No	Yes (IWDTCSTPR)
Best For	Development, debugging	Production safety
Timeout Range	4 us to 2.2 s	8.5 ms to 17.5 s

Key Features

- 14-bit down counter using PCLKB peripheral clock
- Configurable timeout period: 1024 to 16384 cycles
- Configurable clock division: 4 to 8192
- Optional window protection to detect too-early refresh
- Can be stopped in software (unlike IWDTC)
- Generates reset or NMI on timeout (configurable)

Timeout Calculation

$$T_{timeout} = \frac{TOPS \times CKS}{f_{PCLKB}}$$

Example with PCLKB = 60 MHz, TOPS = 16384, CKS = 8192:

$$T_{timeout} = \frac{16384 \times 8192}{60,000,000} = 2.24 \text{ seconds}$$

Timeout Period Table (PCLKB = 60 MHz)

TOPS	CKS/ $\frac{PCLKB}{4}$	CKS/64	CKS/128	CKS/8192
1024	17 μ s	1.1 ms	2.2 ms	140 ms
4096	68 μ s	4.4 ms	8.7 ms	559 ms
8192	137 μ s	8.7 ms	17.5 ms	1.12 s
16384	273 μ s	17.5 ms	34.9 ms	2.24 s

Window Protection

The WDT supports window protection to detect both late refresh (timeout) and early refresh (software error). The refresh window is defined by:

- RPSS: Window start position (when refresh becomes allowed)
- RPES: Window end position (when refresh becomes prohibited)

Hardware Requirements

Parameter	Value	Notes
Clock Source	PCLKB	60 MHz in STAR configuration
Base Address	0x00088020	8-byte register block
Interrupt Vector	WDT_WOVI	Watchdog overflow (NMI mode)
Register Count	4	WDTRR, WDTCR, WDTSR, WDTRCR

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion
- Rule 2: [OK] N/A (no loops in register definitions)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] All accessor functions are single-statement
- Rule 5: [OK] N/A (hardware layer)
- Rule 6: [OK] Minimal scope
- Rule 7: [OK] N/A (no return values to check)
- Rule 8: [OK] All constants use C23 typed enums
- Rule 9: [OK] No function pointers
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

SOLID Principles

- S: Single responsibility - only WDT register definitions
- O: Open for extension via additional bit field enums
- L: N/A (no inheritance hierarchy)
- I: Minimal interface - only necessary accessor
- D: N/A (hardware register layer)

Module Dependencies

- `<stddef.h>` - `offsetof` macro for static assertions
- `<stdint.h>` - Fixed-width integer types

8.69.2 Data Structure Documentation

8.69.2.1 struct rx_wdt_regs_t

WDT Register Map Structure.

Watchdog Timer (WDT) registers for software-controllable watchdog functionality. Uses PCLKB clock and can be stopped in software (unlike IWDT).

Memory Layout Table

Offset	Size	Field	Type	Description
0x00	1	wdtrr	uint8↔ _t	Refresh Register
0x01	1	reserved0	-	Reserved
0x02	2	wdtcr	uint16↔ _t	Control Register
0x04	2	wdtsr	uint16↔ _t	Status Register
0x06	1	wdtrcr	uint8↔ _t	Reset Control Register
0x07	1	reserved1	-	Reserved
Total	8			(packed, no additional padding)

WDT Refresh Sequence

The watchdog is refreshed by writing a specific sequence to WDTRR:

1. Write 0x00 to WDTRR
2. Write 0xFF to WDTRR

This two-step sequence prevents accidental refresh from single-byte errors.

Initialization Example

```
// Configure WDT for 2-second timeout with window protection
volatile rx_wdt_regs_t* wdt_regs = wdt();

// 1. Configure control register (before starting)
//   TOPS=16384 cycles, CKS=div8192, RPSS=100%, RPES=0%
wdt_regs->wdtcr = k_wdt_tops_16384 | k_wdt_cks_div_8192 |
    k_wdt_rpss_100 | k_wdt_rpes_0;

// 2. Configure to generate reset on timeout
wdt_regs->wdtrcr = k_wdt_rstirqs_reset;

// 3. Start WDT by performing first refresh
wdt_regs->wdtrr = k_wdt_refresh_start; // Write 0x00
wdt_regs->wdtrr = k_wdt_refresh_end;   // Write 0xFF
```

Refresh Example (in main loop)

```

void app_main_loop(void) {
    while (1) {
        // Perform application tasks
        process_commands();
        update_motors();

        // Refresh watchdog (must complete both writes atomically)
        wdt()->wdtrr = k_wdt_refresh_start; // 0x00
        wdt()->wdtrr = k_wdt_refresh_end;   // 0xFF

        // Wait for next cycle
        tx_thread_sleep(10);
    }
}

```

Note

WDT has 4 registers only. WDTCSTPR (count stop) exists for IWDT but NOT for WDT.

Invariant

sizeof(rx_wdt_regs_t) == 8 bytes
 All offsets match RX72N Hardware Manual Ch34

Warning

Refresh must complete both writes (0x00 then 0xFF) atomically
 Do not refresh outside the valid window if window protection is enabled

Collaboration diagram for rx_wdt_regs_t:

Data Fields

uint8_t	reserved0↵ [k_wdt_reserved_after_wdtrr_bytes]	Reserved @ 0x01
uint8_t	reserved1↵ [k_wdt_reserved_after_wdtrcr_bytes]	Reserved @ 0x07
volatile uint16_t	wdtcr	WDT Control Register (WDTCR) @ offset 0x02. Configures timeout period, clock division, and window parameters. Must be configured before starting the WDT (before first refresh). Bit Fields: • Bits 1:0 (TOPS): Timeout period selection • Bits 7:4 (CKS):↵ Clock division ratio • Bits 9:8 (RPES):↵ Window end position • Bits 13:12 (RPSS): Window start position See also wdt_wdtrcr_bits_t Bit definitions
volatile uint8_t	wdtrcr	WDT Reset Control Register (WDTRCR) @ offset 0x06. Selects action on timeout: reset or NMI. Bit 7 (RSTIRQS): • 0: Generate NMI on timeout • 1: Generate internal reset on timeout See also wdt_wdtrcr_bits_t Bit definitions

volatile uint8_t	wdtrr	WDT Refresh Register (WDTRR) @ offset 0x00. Write 0x00 then 0xFF to refresh the watchdog counter. Both writes must complete within the valid window if window protection is enabled. See also wdt_refresh_sequence_t Refresh values Warning Single byte writes are invalid - must write both values in sequence
volatile uint16_t	wdtsr	WDT Status Register (WDTSR) @ offset 0x04. Contains current counter value and error flags. Bit Fields: • Bits 13:0 (CNTVAL): Current down-counter value (read-only) • Bit 14 (UNDFE): Under-flow flag (timeout occurred) • Bit 15 (REFEF): Refresh error flag (window violation) See also wdt_wdtsr_bits_t Bit definitions

8.69.3 Enumeration Type Documentation

8.69.3.1 rx'wdt'addresses't

enum [rx_wdt_addresses_t](#) : uintptr_t

WDT base address constant.

Base address for the Watchdog Timer register block at 0x00088020. The WDT has an 8-byte register space with 4 registers and 2 reserved bytes.

Memory Map

Address	Register	Size	Description
0x00088020	WDTRR	1	Refresh Register
0x00088021	Reserved	1	-
0x00088022	WDTCR	2	Control Register
0x00088024	WDTSR	2	Status Register
0x00088026	WDTRCR	1	Reset Control Register
0x00088027	Reserved	1	-

Since

Version 1.0.0

Enumerator

<code>k_wdt_base_addr</code>	WDT register base address (0x00088020). Verified against RX72N Hardware Manual Ch34
------------------------------	---

Definition at line 172 of file [rx72n_wdt_regs.h](#).

```

00172      : uintptr_t {
00173      /**
00174       * @brief WDT register base address (0x00088020)
00175       * @details Verified against RX72N Hardware Manual Ch34
00176       */
00177      k_wdt_base_addr = 0x00088020,
00178 } rx_wdt_addresses_t;
```

8.69.3.2 wdt`refresh`sequence`t

```
enum wdt\_refresh\_sequence\_t : uint8_t
```

WDT Refresh Register (WDTRR) Write Sequence Values.

The WDT counter is refreshed by writing a specific two-byte sequence:

1. Write 0x00 (`k_wdt_refresh_start`)
2. Write 0xFF (`k_wdt_refresh_end`)

This sequence must complete within the valid refresh window if window protection is enabled, otherwise a refresh error (REFEF) will occur.

Refresh Example

```

// Refresh watchdog (atomic - disable interrupts if needed)
wdt()->wdtrr = k_wdt_refresh_start; // Step 1: Write 0x00
wdt()->wdtrr = k_wdt_refresh_end;   // Step 2: Write 0xFF
```

Warning

Both writes must complete in sequence - partial refresh is invalid
Do not insert other operations between the two writes

00379   */
00380   k_wdt_refresh_start = 0x00,
00381
00382  /**
00383   * @brief Second write value for refresh sequence (0xFF)
00384   * @details Must be written immediately after k_wdt_refresh_start.
00385   * Counter reloads to initial value on completion.
00386   */
00387   k_wdt_refresh_end = 0xFF,
00388 } wdt_refresh_sequence_t;
```

8.69.3.3 `wdt_reserved_sizes_t`

```
enum wdt\_reserved\_sizes\_t : uint8_t
```

WDT register reserved field sizes.

Defines reserved byte counts for structure padding to match hardware layout.

Since

Version 1.0.0

Enumerator

<code>k_wdt_reserved_after_wdtrr_bytes</code>	Reserved byte after WDTRR @ 0x01
<code>k_wdt_reserved_after_wdtrcr_bytes</code>	Reserved byte after WDTRCR @ 0x07

Definition at line 186 of file [rx72n_wdt_regs.h](#).

```

00186      : uint8_t {
00187   k_wdt_reserved_after_wdtrr_bytes = 1, /**< Reserved byte after WDTRR @ 0x01 */
00188   k_wdt_reserved_after_wdtrcr_bytes = 1, /**< Reserved byte after WDTRCR @ 0x07 */
00189 } wdt_reserved_sizes_t;
```

8.69.3.4 wdt_wdter_bits_t

enum [wdt_wdter_bits_t](#) : uint16_t

WDT Control Register (WDTCR) Bit Field Values.

Configuration values for WDT timeout period, clock division, and window protection. These values can be OR'd together to configure WDTCR.

Timeout Period Calculation

$$T_{timeout} = \frac{TOPS \times CKS}{f_{PCLKB}}$$

Timeout Examples (PCLKB = 60 MHz)

Configuration	Timeout
TOPS_1024 + CKS_DIV_4	17 us
TOPS_16384 + CKS_DIV_8192	2.24 s
TOPS_4096 + CKS_DIV_2048	140 ms

Window Protection

Window protection prevents both late refresh (timeout) and early refresh (software error). Configure RPSS for start and RPES for end of window.

Configuration Example

```
// 2-second timeout, no window protection
wdt()->wdtcr = k_wdt_tops_16384 | k_wdt_cks_div_8192 |
    k_wdt_rpss_100 | k_wdt_rpes_0;

// 140ms timeout with 25%-75% refresh window
wdt()->wdtcr = k_wdt_tops_4096 | k_wdt_cks_div_2048 |
    k_wdt_rpss_75 | k_wdt_rpes_25;
```

Warning

Only 6 CKS settings are valid - others are prohibited

Since

Version 1.0.0

Enumerator

k_wdt_tops_1024	1024 cycles timeout (counter loads 0x03FF) Shortest timeout period. Use with larger CKS for practical timeouts.
k_wdt_tops_4096	4096 cycles timeout (counter loads 0x0FFF)
k_wdt_tops_8192	8192 cycles timeout (counter loads 0x1FFF)
k_wdt_tops_16384	16384 cycles timeout (counter loads 0x3FFF) Longest timeout period. Combined with CKS_DIV_8192 gives ~2.24s at 60MHz.
k_wdt_cks_div_4	PCLKB divided by 4 (fastest, shortest timeout). CKS[3:0] = 0001. At 60 MHz: 15 MHz counter clock.
k_wdt_cks_div_64	PCLKB divided by 64. CKS[3:0] = 0100. At 60 MHz: 937.5 kHz counter clock.
k_wdt_cks_div_128	PCLKB divided by 128. CKS[3:0] = 1111. At 60 MHz: 468.75 kHz counter clock.
k_wdt_cks_div_512	PCLKB divided by 512. CKS[3:0] = 0110. At 60 MHz: 117.19 kHz counter clock.
k_wdt_cks_div_2048	PCLKB divided by 2048. CKS[3:0] = 0111. At 60 MHz: 29.3 kHz counter clock.
k_wdt_cks_div_8192	PCLKB divided by 8192 (slowest, longest timeout). CKS[3:0] = 1000. At 60 MHz: 7.32 kHz counter clock.
k_wdt_rpes_75	Window closes at 75% counter remaining. Refresh prohibited when counter < 75% of initial value. Provides early detection of runaway code.
k_wdt_rpes_50	Window closes at 50% counter remaining.
k_wdt_rpes_25	Window closes at 25% counter remaining.
k_wdt_rpes_0	No window end (refresh always allowed until timeout). Use with RPSS_100 to disable window protection entirely.
k_wdt_rpss_25	Window opens at 25% counter remaining. Refresh allowed only when counter < 25% of initial value. Strictest early-refresh detection.
k_wdt_rpss_50	Window opens at 50% counter remaining.
k_wdt_rpss_75	Window opens at 75% counter remaining.
k_wdt_rpss_100	No window start (refresh allowed immediately). Use with RPES_0 to disable window protection entirely.

```

WDT Reset Control Register (WDTRCR) Bit Field Values.

Controls the action taken on WDT timeout or window violation. Choice between generating an internal reset or Non-Maskable Interrupt (NMI).

Register Layout (8-bit)

Bit	Field	R/W	Description
6:↔ 0	-	-	Reserved
7	RSTIRQS	R/W	0=NMI, 1=Reset on timeout

Mode Selection

- Reset Mode (k_wdt_rstirqs_reset): Recommended for production. Ensures system recovers even if NMI handler is corrupted.
- NMI Mode (k_wdt_rstirqs_nmi): Useful for debugging. Allows saving diagnostic info before reset.

Configuration Example

```
// Production: Generate reset on timeout
wdt()->wdtrcr = k_wdt_rstirqs_reset;

// Debug: Generate NMI to capture state before reset
wdt()->wdtrcr = k_wdt_rstirqs_nmi;
```

Since

Version 1.0.0

Enumerator

k_wdt_rcr_rstirqs_pos	RSTIRQS bit position.
k_wdt_rcr_rstirqs_mask	RSTIRQS bit mask.
k_wdt_rstirqs_reset	Generate internal reset on timeout (RSTIRQS=1). Recommended for production. System resets automatically when watchdog times out, ensuring recovery.
k_wdt_rstirqs_nmi	Generate NMI on timeout (RSTIRQS=0). Useful for debugging. NMI handler can log diagnostics before manually resetting. Requires NMI handler implementation.

```

8.69.3.7 wdt_wdtsr_bits_t

```
enum wdt\_wdtsr\_bits\_t : uint16_t
```

WDT Status Register (WDTSR) Bit Field Values.

Contains the current down-counter value and error flags. The counter value can be read at any time; flags indicate timeout or window violation.

Register Layout (16-bit)

Bits	Field	R/W	Description
13:↔ 0	CNTVAL	R	Current counter value
14	UNDFE	R/W	Underflow flag (write 0 to clear)
15	REFEF	R/W	Refresh error flag (write 0 to clear)

Reading Counter Example

```
// Get current counter value
uint16_t counter = wdt()->wdtsr & k_wdt_sr_cntval_mask;

// Calculate remaining time (example with CKS_DIV_8192, PCLKB=60MHz)
// Time per count = 8192 / 60MHz = 136.5 us
float remaining_ms = counter * 0.1365f;
```

Error Checking Example

```
// Check for errors after reset
uint16_t status = wdt()->wdtsr;
if (status & k_wdt_sr_undff) {
    // Watchdog timeout occurred (system was reset)
    rx_log_warn("WDT", "Watchdog reset detected");
    wdt()->wdtsr = ~k_wdt_sr_undff; // Clear flag
}
if (status & k_wdt_sr_refef) {
    // Window violation occurred
    rx_log_error("WDT", "Watchdog window violation");
    wdt()->wdtsr = ~k_wdt_sr_refef; // Clear flag
}
```

00593 } wdt_wdtsr_pos_t;
```

8.69.4 Function Documentation

8.69.4.1 wdt()

```
volatile rx_wdt_regs_t * wdt (
    void ) [inline], [static]
```

Get pointer to WDT registers.

Returns a volatile pointer to the WDT register structure at address 0x00088020. The WDT is a software-controllable watchdog timer that uses the PCLKB peripheral clock.

Returns

Volatile pointer to WDT register structure

Return values

Non-NULL	Always returns valid pointer (hardware address)
----------	---

Precondition

None (hardware register always accessible)

Postcondition

Pointer is valid for the lifetime of program execution

Note

Thread Safety: Safe - returns constant hardware address

This function is always inlined for zero overhead

Example:

```
// Refresh watchdog
wdt()->wdtrr = k_wdt_refresh_start;
wdt()->wdtrr = k_wdt_refresh_end;

// Check counter value
uint16_t counter = wdt()->wdtsr & k_wdt_sr_cntval_mask;
```

00032  * @par WDT vs IWDT Comparison
00033  * | Feature          | WDT (This Module) | IWDT
```

```

00034 * |-----|-----|-----|
00035 * | Clock Source | PCLKB (60 MHz) | Dedicated 120 kHz |
00036 * | Stop in Software | Yes | No (once started) |
00037 * | Debug/Sleep Ctrl | No | Yes (IWDT CSTPR) |
00038 * | Best For | Development, debugging | Production safety |
00039 * | Timeout Range | 4 us to 2.2 s | 8.5 ms to 17.5 s |
00040 *
00041 * @par Key Features
00042 * - 14-bit down counter using PCLKB peripheral clock
00043 * - Configurable timeout period: 1024 to 16384 cycles
00044 * - Configurable clock division: 4 to 8192
00045 * - Optional window protection to detect too-early refresh
00046 * - Can be stopped in software (unlike IWDT)
00047 * - Generates reset or NMI on timeout (configurable)
00048 *
00049 * @par Timeout Calculation
00050 * @f[
00051 *  $T_{\text{timeout}} = \frac{\text{TOPS} \times \text{CKS}}{f_{\text{PCLKB}}}$ 
00052 * @f]
00053 *
00054 * Example with PCLKB = 60 MHz, TOPS = 16384, CKS = 8192:
00055 * @f[
00056 *  $T_{\text{timeout}} = \frac{16384 \times 8192}{60,000,000} = 2.24 \text{ seconds}$ 
00057 * @f]
00058 *
00059 * @par Timeout Period Table (PCLKB = 60 MHz)
00060 * | TOPS | CKS/4 | CKS/64 | CKS/128 | CKS/8192 |
00061 * |-----|-----|-----|-----|
00062 * | 1024 | 17 us | 1.1 ms | 2.2 ms | 140 ms |
00063 * | 4096 | 68 us | 4.4 ms | 8.7 ms | 559 ms |
00064 * | 8192 | 137 us | 8.7 ms | 17.5 ms | 1.12 s |
00065 * | 16384 | 273 us | 17.5 ms | 34.9 ms | 2.24 s |
00066 *
00067 * @par Window Protection
00068 * The WDT supports window protection to detect both late refresh (timeout)
00069 * and early refresh (software error). The refresh window is defined by:
00070 * - **RPSS**: Window start position (when refresh becomes allowed)
00071 * - **RPES**: Window end position (when refresh becomes prohibited)
00072 *
00073 * @startuml
00074 * robust "Refresh Window" as RW
00075 * robust "Counter" as CNT
00076 *

Measured-clock divider (CACR1.TCSS[1:0]) per RX72N HW Manual p.393.

Functions

- `rx_err_t rx_cac_init (const rx\_cac\_config\_t *config)`
Initialize the CAC module with the supplied configuration.
- `rx_err_t rx_cac_start (void)`
Begin CAC measurement (CACR0.CFME = 1).
- `rx_err_t rx_cac_stop (void)`
Stop CAC measurement (CACR0.CFME = 0).
- `bool rx_cac_check (uint32_t *out_count)`
Sample the CAC status and counter buffer, clearing acknowledged flags.
- `rx_err_t rx_cac_deinit (void)`
Tear down the CAC module and put it back in module-stop.

8.71.1 Detailed Description

Clock Frequency Accuracy Measurement Circuit (CAC) Driver API for RX72N.

Public driver API for the RX72N Clock Frequency Accuracy Measurement Circuit (CAC). The CAC compares a measurement-target clock against a reference clock by counting target-clock edges between reference-clock edges, then comparing the count against upper/lower limits set in CAULVR/CALLVR. If the count is outside the window, the FERRF flag is set and (when enabled) a group-interrupt is raised via GROUPBL0.

STAR Usage

STAR uses CAC to watchdog the main-oscillator (MOSC, 24 MHz crystal) against the internal HOCO (16 MHz). A drifted crystal - from aging, mechanical damage, or PCB leakage - would silently corrupt motor-control timing; the FERRF ISR instead triggers motor e-stop.

Typical Configuration

```
rx_cac_config_t cfg = {
    .measured_clock = k_cac_clock_main,    // 24 MHz crystal (MOSC)
    .reference_clock = k_cac_clock_hoco,   // 16 MHz HOCO
    .reference_div   = k_cac_ref_div_1024, // 16 MHz / 1024 = 15.625 kHz
    .caulvr         = 1560,                // Upper count bound
    .callvr         = 1500,                // Lower count bound
    .enable_ferrie  = true,                // Raise IRQ on drift
};
(void)rx_cac_init(&cfg);
(void)rx_cac_start();
```

NASA Power of 10 Compliance

- Rule 1: [OK] No goto / setjmp / recursion
- Rule 2: [OK] All loops bounded
- Rule 3: [OK] No dynamic allocation (static state only)
- Rule 4: [OK] All functions < 60 lines
- Rule 5: [OK] ≥ 2 checks per function (

Precondition

/

Postcondition

)

- Rule 6: [OK] File-scope statics, minimal scope
- Rule 7: [OK] rx_err_t returns, checked via RX_RETURN_ON_ERROR
- Rule 8: [OK] C23 typed enums for all constants
- Rule 9: [OK] Single-level pointers
- Rule 10: [OK] -Wall -Wextra -Werror clean

8.71.2 Data Structure Documentation

8.71.2.1 struct rx'cac'config't

Configuration parameters for [rx_cac_init\(\)](#).

Fully describes one CAC measurement campaign. Callers fill in every field before invoking [rx_cac_init\(\)](#); the driver does not look at partial or uninitialised members.

Example: MOSC watchdog against HOCO

```
rx_cac_config_t cfg = {
    .measured_clock = k_cac_clock_main,
    .reference_clock = k_cac_clock_hoco,
    .target_div     = k_cac_target_div_1,
    .reference_div   = k_cac_ref_div_1024,
    .caulvr         = 1560,
    .callvr         = 1500,
    .enable_ferrie  = true,
    .enable_mendie  = false,
    .enable_ovfie   = true,
};
```

Invariant

callvr < caulvr (driver rejects otherwise)

Since

Version 1.0.0

Definition at line 157 of file [rx_cac.h](#).

Collaboration diagram for rx_cac_config_t:

Data Fields

uint16_t	callvr	Lower-limit counter value - CALLVR. FERRF asserts when (counter < callvr) at sampling time.
uint16_t	caulvr	Upper-limit counter value - CAULVR. FERRF asserts when (counter > caulvr) at sampling time.

bool	enable_ferrie	Enable frequency-error interrupt (CAICR.FERRIE). When true, the CAC raises an IRQ on every transition into the "counter outside [callvr, caulvr]" state. Must be used together with a GROUPBL0 IRQ handler wired to bit 26 (FERRF).
bool	enable_mendie	Enable measurement-end interrupt (CAICR.MENDIE).
bool	enable_ovfie	Enable counter-overflow interrupt (CAICR.OVFIE).
rx_cac_clock_t	measured_clock	Measured (target) clock source - CACR1.FMCS[2:0]. The clock whose frequency is being evaluated. All eight sources defined by rx_cac_clock_t are legal here.
rx_cac_clock_t	reference_clock	Reference clock source - CACR2.RSCS[2:0]. The clock the measurement is compared against. Only the first six entries of rx_cac_clock_t are legal (Main..IWDTCCLK); passing k_cac_clock_uclk or k_cac_clock_clkout25 causes rx_cac_init() to return k_err_invalid_arg .
rx_cac_ref_div_t	reference_div	Divider applied to the reference clock - CACR2.RCDS[1:0]. Selects how many reference-clock edges accumulate into a single measurement window (32 / 128 / 1024 / 8192).
rx_cac_target_div_t	target_div	Divider applied to the measured clock - CACR1.TCSS[1:0]. Defaults to k_cac_target_div_1 for highest-resolution counts.

8.71.3 Enumeration Type Documentation

8.71.3.1 `rx_cac_clock_t`

```
enum rx\_cac\_clock\_t : uint8_t
```

Clock source selector for CAC measured/reference inputs.

Maps directly onto the FMCS[2:0] / RSCS[2:0] field values defined in CACR1 / CACR2 (RX72N HW Manual p.393 / p.394). Not every source is legal as a reference - RSCS supports values 000-101 only (Main, Sub, HOCO, LOCO, PCLKB, IWDTCCLK); the extra values (UCLK, CLKOUT25M) are measured-only.

Since

Version 1.0.0

Enumerator

k_cac_clock_main	Main-clock oscillator (MOSC, external crystal)
k_cac_clock_sub	Sub-clock oscillator (32.768 kHz)
k_cac_clock_hoco	High-speed on-chip oscillator
k_cac_clock_loco	Low-speed on-chip oscillator
k_cac_clock_pclkb	Peripheral clock B

k_cac_clock_iwdtclk	IWDT-dedicated oscillator
k_cac_clock_uclk	USB clock (measured-only, not a valid RSCS)
k_cac_clock_clkout25	25 MHz CLKOUT (measured-only, not a valid RSCS)

Definition at line 83 of file [rx_cac.h](#).

```

00083      : uint8_t {
00084  k_cac_clock_main    = 0, /**< Main-clock oscillator (MOSC, external crystal) */
00085  k_cac_clock_sub     = 1, /**< Sub-clock oscillator (32.768 kHz) */
00086  k_cac_clock_hoco    = 2, /**< High-speed on-chip oscillator */
00087  k_cac_clock_loco    = 3, /**< Low-speed on-chip oscillator */
00088  k_cac_clock_pclkb   = 4, /**< Peripheral clock B */
00089  k_cac_clock_iwdtclk = 5, /**< IWDT-dedicated oscillator */
00090  k_cac_clock_uclk    = 6, /**< USB clock (measured-only, not a valid RSCS) */
00091  k_cac_clock_clkout25 = 7, /**< 25 MHz CLKOUT (measured-only, not a valid RSCS) */
00092 } rx_cac_clock_t;

```

8.71.3.2 rx_cac_ref_div_t

```
enum rx\_cac\_ref\_div\_t : uint8_t
```

Reference-clock divider (CACR2.RCDS[1:0]) per RX72N HW Manual p.394.

Since

Version 1.0.0

Enumerator

k_cac_ref_div_32	Reference clock / 32
k_cac_ref_div_128	Reference clock / 128
k_cac_ref_div_1024	Reference clock / 1024
k_cac_ref_div_8192	Reference clock / 8192

Definition at line 99 of file [rx_cac.h](#).

```

00099      : uint8_t {
00100  k_cac_ref_div_32    = 0, /**< Reference clock / 32 */
00101  k_cac_ref_div_128   = 1, /**< Reference clock / 128 */
00102  k_cac_ref_div_1024  = 2, /**< Reference clock / 1024 */
00103  k_cac_ref_div_8192  = 3, /**< Reference clock / 8192 */
00104 } rx_cac_ref_div_t;

```

8.71.3.3 rx_cac_target_div_t

```
enum rx\_cac\_target\_div\_t : uint8_t
```

Measured-clock divider (CACR1.TCSS[1:0]) per RX72N HW Manual p.393.

TCSS is a target-clock divider (not a digital filter). Use /1 for the fastest allowed count rate and larger dividers only when the measurement target clock exceeds the counter bandwidth.

Since

Version 1.0.0

Enumerator

k_cac_target_div_1	Target clock / 1
k_cac_target_div_4	Target clock / 4
k_cac_target_div_8	Target clock / 8
k_cac_target_div_32	Target clock / 32

Definition at line 117 of file [rx_cac.h](#).

```

00117      : uint8_t {
00118  k_cac_target_div_1 = 0, /**< Target clock / 1 */
00119  k_cac_target_div_4 = 1, /**< Target clock / 4 */
00120  k_cac_target_div_8 = 2, /**< Target clock / 8 */
00121  k_cac_target_div_32 = 3, /**< Target clock / 32 */
00122 } rx_cac_target_div_t;

```

8.71.4 Function Documentation

8.71.4.1 rx_cac_check()

```

bool rx_cac_check (
    uint32_t * out_count)

```

Sample the CAC status and counter buffer, clearing acknowledged flags.

Reads CASTR, optionally writes back FERRE / MENDE / OVFF acknowledgement bits via CAICR, and returns the last-captured counter buffer via out_count. If out_count is nullptr the counter is not returned; the function still reads/acks CASTR.

Parameters

out	out_count	Optional pointer that receives CACNTBR on success.
-----	-----------	--

Returns

bool

Return values

true	FERRE was set at read time (frequency outside limits)
false	FERRE was not set

Precondition

[rx_cac_init\(\)](#) returned k_rx_ok (driver returns false otherwise)

Postcondition

CASTR.FERRF / MENDF / OVFF are cleared (write-1-clear via CAICR)

Note

Safe to call from ISR context provided out_count is ISR-local.

Since

Version 1.0.0

Sample the CAC status and counter buffer, clearing acknowledged flags.

Reads CASTR (status), latches the current CACNTBR (counter buffer) value if out_count is non-NULL, then issues a write-1-clear to the IRQ status flags in CAICR (preserving the IRQ enables). Returns whether the FERRF (frequency-error) flag was set since the last check.

Note

Safe from any context including ISR (single register read + write, no blocking).

Definition at line 314 of file [rx_cac.c](#).

```
00315 {
00316     if (!s_initialized) {
00317         return false;
00318     }
00319     volatile rx_cac_regs_t* regs = cac();
00320     uint8_t status = regs->castr;
00321     if (out_count != nullptr) {
00322         *out_count = (uint32_t)regs->cacntbr;
00323     }
00324     /* Preserve enabled IRQ settings while issuing write-1-clear acknowledgements. */
00325     uint8_t ack =
00326         (uint8_t)(regs->caicr & (uint8_t)(k_cac_caicr_ferrie_mask | k_cac_caicr_mendie_mask |
00327                                         k_cac_caicr_ovfie_mask));
00328     ack |= k_cac_caicr_clear_all_flags;
00329     regs->caicr = ack;
00330     return (bool)((status & k_cac_castr_ferrf_mask) != 0U);
00331 }
```

References [cac\(\)](#), [rx_cac_regs_t::cacntbr](#), [rx_cac_regs_t::caicr](#), [rx_cac_regs_t::castr](#), [k_cac_caicr_clear_all_flags](#), [k_cac_caicr_ferrie_mask](#), [k_cac_caicr_mendie_mask](#), [k_cac_caicr_ovfie_mask](#), [k_cac_castr_ferrf_mask](#), and [s_initialized](#).

Here is the call graph for this function:

8.71.4.2 rx_cac_deinit()

```
rx_err_t rx_cac_deinit (
    void ) [nodiscard]
```

Tear down the CAC module and put it back in module-stop.

Clears CACR0.CFME, disables all interrupt enables, clears status flags, then asserts MSTPCRC.↔ MSTPC19 to power the module down. Init state is reset so a subsequent [rx_cac_init\(\)](#) call is permitted.

Returns

rx_err_t Error code

Return values

k_rx_ok	Module stopped and powered down
k_rx_err_not_initialized	rx_cac_init() not called

Precondition

[rx_cac_init\(\)](#) returned k_rx_ok

Postcondition

CACR0.CFME = 0 and MSTPCRC.MSTPC19 = 1

Since

Version 1.0.0

Tear down the CAC module and put it back in module-stop.

Stops the measurement (CFME=0), clears CACR1 / CACR2 (resetting the reference clock and tolerance), clears all IRQ flags via CAICR, then gates the CAC module clock through [internal_module_stop\(\)](#). Marks the driver as uninitialized.

Note

Not thread-safe. Serialize all rx_cac_* operations.

Definition at line 344 of file [rx_cac.c](#).

```
00345 {
00346     if (!s_initialized) {
00347         rx_log_error(s_tag, "rx_cac_deinit: not initialized");
00348         return k_rx_err_not_initialized;
00349     }
00350     volatile rx_cac_regs_t* regs = cac();
00351     regs->cacr0 = k_cac_cacr0_cfme_stop;
00352     regs->cacr1 = 0U;
00353     regs->cacr2 = 0U;
00354     regs->caicr = k_cac_caicr_clear_all_flags;
00355     internal_module_stop();
00356     s_initialized = false;
00357     return k_rx_ok;
00358 }
```

References [cac\(\)](#), [rx_cac_regs_t::cacr0](#), [rx_cac_regs_t::cacr1](#), [rx_cac_regs_t::cacr2](#), [rx_cac_regs_t::caicr](#), [internal_module_stop\(\)](#), [k_cac_cacr0_cfme_stop](#), [k_cac_caicr_clear_all_flags](#), [s_initialized](#), and [s_tag](#).

Here is the call graph for this function:

8.71.4.3 rx'cac'init()

```
rx_err_t rx_cac_init (
    const rx_cac_config_t * config)  [nodiscard]
```

Initialize the CAC module with the supplied configuration.

Performs the full CAC bring-up sequence mandated by the RX72N HW Manual Ch10.3 "Operation":

1. Unlock PRCR.PRC1 and clear MSTPCRC.MSTPC19, then re-lock PRCR.
2. With CACR0.CFME = 0, program CACR1 (FMCS, TCSS, EDGES, CAIE), CACR2 (RSCS, RCDS, RPS, DFS), CAULVR, CALLVR, and CAICR enables.
3. Clear any stale CASTR flags via CAICR write-1-clear.
4. Leave CFME = 0 (caller must invoke [rx_cac_start\(\)](#) to begin measuring).

Parameters

in	config	Pointer to configuration struct (must not be nullptr)
----	--------	---

Returns

rx_err_t Error code

Return values

k_rx_ok	Initialization succeeded, CAC ready
k_rx_err_null_ptr	config is nullptr
k_rx_err_invalid_arg	Invalid clock/divider, or callvr >= caulvr
k_rx_err_invalid_state	CAC already initialized (call deinit first)

Precondition

config != nullptr

config->callvr < config->caulvr

config->reference_clock is in [k_cac_clock_main .. k_cac_clock_iwdtlk]

config->measured_clock is in [k_cac_clock_main .. k_cac_clock_clkout25]

config->target_div is in [k_cac_target_div_1 .. k_cac_target_div_32]

config->reference_div is in [k_cac_ref_div_32 .. k_cac_ref_div_8192]

Postcondition

CAC module is powered on (MSTPCRC.MSTPC19 = 0)
CACR0.CFME = 0 (measurement not yet running)
All configured limits and interrupt enables are loaded

Note

Not thread-safe. Call only during single-threaded initialization.

Since

Version 1.0.0

    void ) [nodiscard]
```

Begin CAC measurement (CACR0.CFME = 1).

Returns

rx_err_t Error code

Return values

k_rx_ok	Measurement started
k_rx_err_not_initialized	rx_cac_init() not called

Precondition

[rx_cac_init\(\)](#) returned k_rx_ok

Postcondition

CACR0.CFME = 1

Since

Version 1.0.0

Begin CAC measurement (CACR0.CFME = 1).

Sets CACR0.CFME=1 to enable comparison of the measurement clock against the reference clock configured by [rx_cac_init\(\)](#). Subsequent calls to [rx_cac_check\(\)](#) will report whether the measurement is within the configured tolerance window and return the latched count.

Note

Not thread-safe. Serialize all rx_cac_* operations.

Definition at line 271 of file [rx_cac.c](#).

```
00272 {
00273     if (!s_initialized) {
00274         rx_log_error(s_tag, "rx_cac_start: not initialized");
00275         return k_rx_err_not_initialized;
00276     }
00277     cac()->cacr0 = k_cac_cacr0_cfme_start;
00278     return k_rx_ok;
00279 }
```

References [cac\(\)](#), [rx_cac_regs_t::cacr0](#), [k_cac_cacr0_cfme_start](#), [s_initialized](#), and [s_tag](#).

Here is the call graph for this function:

8.71.4.5 rx_cac_stop()

```
rx_err_t rx_cac_stop (
    void ) [nodiscard]
```

Stop CAC measurement (CACR0.CFME = 0).

Returns

rx_err_t Error code

Return values

k_rx_ok	Measurement stopped
k_rx_err_not_initialized	rx_cac_init() not called

Precondition

[rx_cac_init\(\)](#) returned k_rx_ok

Postcondition

CACR0.CFME = 0

Since

Version 1.0.0

Stop CAC measurement (CACR0.CFME = 0).

Clears CACR0.CFME, halting the measurement counter. The measurement configuration (reference clock, tolerance, IRQ enables) is preserved so a subsequent [rx_cac_start\(\)](#) resumes from a clean state. Useful when entering low-power modes or when switching reference clocks.

Note

Not thread-safe. Serialize all rx_cac_* operations.

Definition at line 292 of file [rx_cac.c](#).

```
00293 {
00294     if (!s_initialized) {
00295         rx_log_error(s_tag, "rx_cac_stop: not initialized");
00296         return k_rx_err_not_initialized;
00297     }
00298     cac()->cacr0 = k_cac_cacr0_cfme_stop;
00299     return k_rx_ok;
00300 }
```

00001 /**
00002  * @file rx_cac.h
00003  * @brief Clock Frequency Accuracy Measurement Circuit (CAC) Driver API for RX72N
00004  *
00005  * @details
00006  * Public driver API for the RX72N Clock Frequency Accuracy Measurement
00007  * Circuit (CAC). The CAC compares a measurement-target clock against a
00008  * reference clock by counting target-clock edges between reference-clock
00009  * edges, then comparing the count against upper/lower limits set in
00010  * CAULVR/CALLVR. If the count is outside the window, the FERRF flag is set
00011  * and (when enabled) a group-interrupt is raised via GROUPBL0.
00012  *
00013  * @par STAR Usage
00014  * STAR uses CAC to watchdog the main-oscillator (MOSC, 24 MHz crystal)
00015  * against the internal HOCO (16 MHz). A drifted crystal - from aging,
00016  * mechanical damage, or PCB leakage - would silently corrupt motor-control
00017  * timing; the FERRF ISR instead triggers motor e-stop.
00018  *
00019  * @par Typical Configuration
00020  * @code{.c}
00021  * rx_cac_config_t cfg = {
00022  *     .measured_clock = k_cac_clock_main,    // 24 MHz crystal (MOSC)
00023  *     .reference_clock = k_cac_clock_hoco,    // 16 MHz HOCO
00024  *     .reference_div   = k_cac_ref_div_1024,  // 16 MHz / 1024 = 15.625 kHz
00025  *     .caulvr          = 1560,                // Upper count bound
00026  *     .callvr          = 1500,                // Lower count bound
00027  *     .enable_ferrie   = true,                // Raise IRQ on drift
00028  * };
00029  * (void)rx_cac_init(&cfg);
00030  * (void)rx_cac_start();

CMT (Compare Match Timer) Driver API for RX72N - Periodic Interrupt Generation.

```
#include <stdint.h>
```

```
#include "rx_err.h"
```

Include dependency graph for rx_cmt.h:

This graph shows which files directly or indirectly include this file:

Data Structures

- struct [rx_cmt_config_t](#)
CMT channel configuration structure.

Typedefs

- typedef void(* [rx_cmt_callback_t](#)) (void *user_data)
CMT interrupt callback function type.

Enumerations

- enum [rx_cmt_channel_t](#) : uint8_t { [k_cmt_channel_0](#) = 0 , [k_cmt_channel_1](#) = 1 , [k_cmt_channel_2](#) = 2 , [k_cmt_channel_3](#) = 3 }
- CMT channel identifiers.

Functions

- `rx_err_t rx_cmt_init (rx_cmt_channel_t channel, const rx_cmt_config_t *config)`
Initialize CMT channel for periodic interrupts.
- `rx_err_t rx_cmt_start (rx_cmt_channel_t channel)`
Start CMT timer.
- `rx_err_t rx_cmt_stop (rx_cmt_channel_t channel)`
Stop CMT timer.
- `rx_err_t rx_cmt_get_count (rx_cmt_channel_t channel, uint16_t *count)`
Get CMT counter value.
- `rx_err_t rx_cmt_deinit (rx_cmt_channel_t channel)`
Deinitialize CMT channel.

8.73.1 Detailed Description

CMT (Compare Match Timer) Driver API for RX72N - Periodic Interrupt Generation.

8.73.2 Overview

The Compare Match Timer (CMT) driver provides periodic interrupt generation for the RX72N microcontroller. CMT is used for system timing, motor control loops, and other periodic tasks requiring precise timing.

8.73.2.1 CMT Hardware Overview

The RX72N has 4 CMT channels organized in 2 units:

8.73.2.2 Channel Allocation

Channel	Usage	Frequency	Description
CMT0	ThreadX	100 Hz	System tick (RESERVED)
CMT1	Motor	100-1000 Hz	Motor control loop
CMT2	Available	User-defined	General purpose
CMT3	Available	User-defined	General purpose

Warning

CMT0 is reserved for ThreadX system tick. Do not use CMT0 with this API.

8.73.2.3 CMT Operation Principle

8.73.2.4 Clock Divider Selection

Divider	CKS Value	Clock Rate	Min Freq	Max Freq	Notes
PCLKB/ $\frac{60}{8}$	0b00	7.5 MHz	115 Hz	7.5 MHz	High resolution
PCLKB/32	0b01	1.875 MHz	29 Hz	1.875 MHz	Medium resolution
PCLKB/128	0b10	468.75 kHz	7.2 Hz	468 kHz	Recommended
PCLKB/512	0b11	117.2 kHz	1.8 Hz	117 kHz	Low frequency

Calculation example for 250 Hz motor control loop:

PCLKB = 60 MHz

Divider = 128 -> Counter clock = 468.75 kHz

Period = $468750 / 250 = 1875$ counts

8.73.2.5 Memory-Mapped Register Layout

Register	Offset	Description
CMSTR0	0x0000	Start register for CMT0/CMT1
CMSTR1	0x0010	Start register for CMT2/CMT3
CMCRn	+0x00	Control register (clock select, interrupt enable)
CMCNTn	+0x02	16-bit counter register
CMCORn	+0x04	16-bit compare match register

8.73.2.6 NASA Power of 10 Compliance

Rule	Status	Implementation
Rule 1: Control flow	↔ [PASS]↔	No goto, setjmp, or recursion
Rule 2: Loop bounds	↔ [PASS]↔	Bounded divider search (4 iterations max)
Rule 3: No heap	↔ [PASS]↔	Static callback arrays only
Rule 4: Function length	↔ [PASS]↔	All functions under 60 lines
Rule 5: Assertions	↔ [PASS]↔	Parameter validation in all functions
Rule 6: Data scope	↔ [PASS]↔	File-scope static with s_ prefix
Rule 7: Return checks	↔ [PASS]↔	All internal calls checked
Rule 8: Preprocessor	↔ [PASS]↔	C23 typed enums for all constants
Rule 9: Pointers	↔ [PASS]↔	Single-level only (callback + user_data)
Rule 10: Warnings	↔ [PASS]↔	-Wall -Wextra -Werror clean

8.73.2.7 SOLID Principles

Principle	Application
S - Single Responsibility	CMT driver handles only compare match timers
O - Open/Closed	Extended via callback registration
L - Liskov Substitution	All channels use identical API
I - Interface Segregation	Simple 5-function API
D - Dependency Inversion	Callback injection for user code

8.73.2.8 Module Dependencies

8.73.3 Data Structure Documentation

8.73.3.1 struct rx_cmt_config_t

CMT channel configuration structure.

Configuration parameters for initializing a CMT channel. All fields must be set before calling [rx_cmt_init\(\)](#).

8.73.3.2 Memory Layout

Offset	Field	Size	Description
0x00	frequency_hz	4	Target interrupt frequency
0x04	callback	4	Interrupt callback pointer
0x08	user_data	4	User data for callback
0x0C	priority	1	Interrupt priority level

Total size: 13 bytes (16 with padding)

8.73.3.3 Frequency Calculation

The driver automatically selects the best clock divider for the requested frequency. Valid range depends on PCLKB (60 MHz):

- Minimum: ~1.8 Hz (with /512 divider)
- Maximum: ~7.5 MHz (with /8 divider)

8.73.3.4 Example Configuration

```
rx_cmt_config_t config = {
    .frequency_hz = 250,           // 250 Hz motor control
    .callback = motor_tick_handler,
    .user_data = &motor_context,
    .priority = 8                 // Medium priority
};
```

Since

Version 1.0.0

Definition at line 292 of file [rx_cmt.h](#).

Collaboration diagram for rx_cmt_config_t:

Data Fields

rx_cmt_callback_t	callback	Interrupt callback function. Function called on each compare match interrupt. May be NULL if no callback needed (timer runs but no notification). See also rx_cmt_callback_t Callback function signature
uint32_t	frequency_hz	Desired interrupt frequency in Hz. Target frequency for periodic interrupts. Driver selects optimal divider. Valid range: 1-7500000 Hz (depends on PCLKB). Note Actual frequency may differ slightly due to integer division.
uint8_t	priority	Interrupt priority level (0-15). ICU interrupt priority. Higher values = higher priority. • 0: Lowest priority (may be masked) • 15: Highest priority Note Motor control typically uses priority 8-12. Warning Priority 0 disables the interrupt.

<code>void *</code>	<code>user_data</code>	User data passed to callback. Opaque pointer passed to callback on each invocation. Typically used to pass context or state to the callback handler. Note May be NULL if callback doesn't need user data.
---------------------	------------------------	--

8.73.4 Typedef Documentation

8.73.4.1 `rx_cmt_callback_t`

```
typedef void(* rx_cmt_callback_t) (void *user_data)
```

CMT interrupt callback function type.

User-provided function called from CMT interrupt context on each compare match. Keep callbacks short and non-blocking to avoid interrupt latency issues.

8.73.4.2 Callback Execution Context

- Interrupt level: IPL equal to configured priority
- Stack: Interrupt stack (not task stack)
- Timing: Called every compare match period
- Duration: Keep under 10 us for real-time performance

8.73.4.3 Allowed Operations

Operation	Allowed	Notes
Set flag	↔ [PASS]↔	Signal task to process
Write GPIO	↔ [PASS]↔	Toggle debug pin
Queue message	↔ [PASS]↔	Use ThreadX queue
Blocking call	↔ [FAIL]↔	Causes interrupt overrun
Memory allocation	↔ [FAIL]↔	NASA Rule 3 violation

Operation	Allowed	Notes
Long computation	↔ [FAIL]↔	Delays other interrupts

Parameters

in	user_data	User data pointer provided during rx_cmt_init() May be NULL if no user data needed.
----	-----------	---

Note

Callback executes in interrupt context. Keep it fast!

Warning

Do not call blocking functions from callback.

Do not disable interrupts for extended periods.

Example:

```
static volatile bool s_motor_tick = false;

void motor_timer_callback(void* user_data) {
    (void)user_data;
    s_motor_tick = true; // Signal motor task
}
```

8.73.5 Enumeration Type Documentation

8.73.5.1 rx`cmt`channel`_t

```
enum rx\_cmt\_channel\_t : uint8_t
```

CMT channel identifiers.

Identifies the 4 available CMT channels. Channels are grouped into units:

- Unit 0: CMT0, CMT1 (shared CMSTR0)
- Unit 1: CMT2, CMT3 (shared CMSTR1)

8.73.5.2 Channel Assignment

Channel	Purpose	Notes
k_cmt_channel_0	ThreadX tick	RESERVED - Do not use
k_cmt_channel_1	Motor control	100-1000 Hz typical
k_cmt_channel_2	User defined	Available
k_cmt_channel_3	User defined	Available

See also

[rx_cmt_init\(\)](#) Channel selection for initialization

Since

Version 1.0.0

Enumerator

k_cmt_channel_0	CMT0 - Reserved for ThreadX system tick (100 Hz)
k_cmt_channel_1	CMT1 - Motor control loop (user configurable)
k_cmt_channel_2	CMT2 - Available for general use
k_cmt_channel_3	CMT3 - Available for general use

Definition at line 196 of file [rx_cmt.h](#).

```

00196     : uint8_t {
00197   k_cmt_channel_0 = 0, /**< CMT0 - Reserved for ThreadX system tick (100 Hz) */
00198   k_cmt_channel_1 = 1, /**< CMT1 - Motor control loop (user configurable) */
00199   k_cmt_channel_2 = 2, /**< CMT2 - Available for general use */
00200   k_cmt_channel_3 = 3, /**< CMT3 - Available for general use */
00201 } rx_cmt_channel_t;

```

8.73.6 Function Documentation

8.73.6.1 rx_cmt_deinit()

```

rx_err_t rx_cmt_deinit (
    const rx\_cmt\_channel\_t channel) [nodiscard]

```

Deinitialize CMT channel.

Stops timer, disables interrupts, clears callback, and marks channel as uninitialized. Channel can be reinitialized with [rx_cmt_init\(\)](#) after this.

Parameters

in	channel	CMT channel to deinitialize Valid range: k_cmt_channel_0 to k_cmt_channel_3
----	---------	---

Returns

rx_err_t Deinitialization status

Return values

k_rx_ok	Channel deinitialized successfully
k_rx_err_invalid_arg	Invalid channel number
k_rx_err_hw_error	Hardware failed to stop

Postcondition

Timer stopped
Interrupt disabled
Callback cleared
Channel marked as uninitialized

Note

Does not re-enable module stop bit (CMT module remains powered).

Thread Safety:

Not thread-safe. Ensure no callbacks executing during deinit.

See also

[rx_cmt_init\(\)](#) Reinitialize channel

Since

Version 1.0.0

Deinitialize CMT channel.

Stops the CMT counter, disables the ICU interrupt for the channel, clears the stored callback and user data, and marks the channel as uninitialized. After this call the channel may be re-initialized with [rx_cmt_init\(\)](#).

Algorithm steps:

1. Validate channel range
2. Stop timer via [rx_cmt_stop\(\)](#) and propagate any error
3. Compute ICU vector, IER index, and IER bit for the channel
4. Clear the IER bit to disable the interrupt
5. Clear callback, user_data, and initialized flag

Precondition

channel must be in range [0, 3]

Caller should ensure no other task is using the channel callback

Postcondition

Counter halted (CMSTR bit cleared)

ICU interrupt disabled for channel

s_cmt_initialized[channel] set to false

s_cmt_callback[channel] and s_cmt_user_data[channel] set to nullptr

Note

Safe to call on an uninitialized channel (rx_cmt_stop tolerates it)

Module clock is NOT re-asserted - hardware remains clocked for re-use

Thread Safety:

Not thread-safe. Ensure no ISR or other thread is using the channel.

Example:

```
rx_err_t err = rx_cmt_deinit(k_cmt_channel_1);
if (err != k_rx_ok) {
    rx_log_error("APP", "CMT deinit failed");
}
```

See also

[rx_cmt_init\(\)](#) Re-initialize after deinit

01400     }
01401
01402     /* Disable interrupt only for channels with fixed ICU vectors (CMI0/CMI1).
01403      * CMI2/CMI3 are SELECTB sources; interrupt wiring for those is not
01404      * implemented (see internal_configure_cmt_interrupt() for details). */
01405     if (channel == k_cmt_channel_0 || channel == k_cmt_channel_1) {
01406         const uint8_t vector = k_vect_cmt0_cmi0 + channel;
01407         const uint8_t ier_index = vector / k_icu_ier_bits_per_reg;
01408         const uint8_t ier_bit = vector % k_icu_ier_bits_per_reg;
01409         const uint8_t ier_mask = (uint8_t)(k_cmt_bit_mask_lsb « ier_bit);
01410         icu()->ier[ier_index] &= (uint8_t)~ier_mask;
01411     }
```

```

01412
01413  /* Clear callback */
01414  s_cmt_callback[channel] = nullptr;
01415  s_cmt_user_data[channel] = nullptr;
01416  s_cmt_initialized[channel] = false;
01417
01418  rx_log_info(s_tag, "CMT deinitialized");
01419
01420  return k_rx_ok;
01421 }

```

References [icu\(\)](#), [rx_icu_regs_t::ier](#), [k_cmt_bit_mask_lsb](#), [k_cmt_channel_0](#), [k_cmt_channel_1](#), [k_cmt_max_channels](#), [k_icu_ier_bits_per_reg](#), [k_vect_cmt0_cmi0](#), [rx_cmt_stop\(\)](#), [s_cmt_callback](#), [s_cmt_initialized](#), [s_cmt_user_data](#), and [s_tag](#).

Here is the call graph for this function:

8.73.6.2 rx'cmt'get'count()

```

rx_err_t rx_cmt_get_count (
    const rx_cmt_channel_t channel,
    uint16_t * count) [nodiscard]

```

Get CMT counter value.

Reads the current 16-bit counter value. Useful for timing measurements or debugging. Counter resets to 0 on each compare match.

Parameters

in	channel	CMT channel to read Valid range: k_cmt_channel_0 to k_cmt_channel_3
out	count	Pointer to store counter value (0-65535)

Returns

rx_err_t Read status

Return values

k_rx_ok	Counter value read successfully
k_rx_err_null_ptr	count pointer is nullptr
k_rx_err_invalid_arg	Invalid channel number
k_rx_err_invalid_state	Channel not initialized

Precondition

Channel initialized via [rx_cmt_init\(\)](#)
count != nullptr

Postcondition

*count contains current counter value

Note

Counter may change immediately after reading if timer running.

Thread Safety:

Safe to call from multiple threads (atomic 16-bit read).

See also

[rx_cmt_stop\(\)](#) Stop timer to freeze counter

Since

Version 1.0.0

Get CMT counter value.

Returns the instantaneous value of the 16-bit CMCNT register for the specified channel. The counter increments at PCLKB divided by the configured divider (/8, /32, /128, or /512) and resets to 0 on compare match. Useful for measuring elapsed time within a period.

Precondition

Channel must be initialized via [rx_cmt_init\(\)](#)
count must point to valid uint16_t storage

Postcondition

*count set to CMCNT register value at time of read
Counter continues running (read is non-destructive)

Note

Value may change between consecutive reads if counter is running
For precise time measurements disable interrupts around consecutive reads

Thread Safety:

Read-only; safe to call from multiple contexts, but value may be stale.

Example:

```
uint16_t ticks = 0;
rx_err_t err = rx_cmt_get_count(k_cmt_channel_1, &ticks);
if (err == k_rx_ok) {
    // ticks = current counter position within the period
}
```

Definition at line 1326 of file [rx_cmt.c](#).

```
01327 {
01328     const volatile rx_cmt_channel_regs_t* cmt = nullptr;
01329
01330     RX_CHECK_NULL_PTR(count, s_tag, "count pointer is nullptr");
01331
01332     if ((uint8_t)channel >= k_cmt_max_channels || !s_cmt_initialized[channel]) {
01333         return k_rx_err_invalid_state;
01334     }
01335
01336     cmt = internal_get_cmt_base(channel);
01337     if (cmt == nullptr) {
01338         return k_rx_err_invalid_arg;
01339     }
01340
01341     *count = cmt->cmcnt;
01342     return k_rx_ok;
01343 }
```

References [rx_cmt_channel_regs_t::cmcnt](#), [internal_get_cmt_base\(\)](#), [k_cmt_max_channels](#), [s_cmt_initialized](#), and [s_tag](#).

Here is the call graph for this function:

8.73.6.3 rx'cmt'init()

```
rx_err_t rx_cmt_init (
    const rx_cmt_channel_t channel,
    const rx_cmt_config_t * config) [nodiscard]
```

Initialize CMT channel for periodic interrupts.

Configures a CMT channel for periodic interrupt generation at the specified frequency. The timer starts immediately after initialization.

8.73.6.4 Initialization Sequence

8.73.6.5 Divider Auto-Selection

The driver automatically selects the smallest divider that produces a period fitting in the 16-bit compare register:

Frequency	Divider	Period	Actual Freq
1000 Hz	/32	1875	1000.00 Hz
250 Hz	/128	1875	250.00 Hz
100 Hz	/128	4687	100.02 Hz
10 Hz	/512	11719	10.00 Hz

Parameters

in	channel	CMT channel to initialize (1-3, CMT0 reserved) Valid range: k_cmt_channel_1 to k_cmt_channel_3
in	config	Pointer to configuration structure (must not be NULL)

Returns

`rx_err_t` Initialization status

Return values

<code>k_rx_ok</code>	Channel initialized and started successfully
<code>k_rx_err_null_ptr</code>	config is nullptr
<code>k_rx_err_invalid_arg</code>	Invalid channel, frequency out of range, or invalid priority
<code>k_rx_err_conflict</code>	Channel is CMT0 (reserved for ThreadX)

Precondition

Module stop cleared for CMT (or will be cleared by this function)

Channel not currently in use (call `rx_cmt_deinit()` first if reinitializing)

config->frequency_hz > 0 and within achievable range

config->priority in range [1, 15] (0 disables interrupt)

Postcondition

CMT channel running at specified frequency

Callback registered and will be called on each compare match

Interrupt enabled at specified priority

Note

Timer starts automatically. Use `rx_cmt_stop()` to pause.

CMT0 is reserved for ThreadX - returns `k_rx_err_conflict`.

Warning

Do not initialize CMT0 - it's managed by ThreadX.

High frequencies (>100 kHz) may cause excessive interrupt load.

Thread Safety:

Not thread-safe. Call from single thread only, typically during init.

Performance:

- Execution time: ~50 us @ 240 MHz
- Stack usage: ~64 bytes

Example - Motor Control Timer:

```
static void motor_tick(void* user_data) {
    motor_context_t* ctx = (motor_context_t*)user_data;
    ctx->tick_count++;
}

void motor_timer_init(void) {
    static motor_context_t s_motor_ctx;

    rx_cmt_config_t config = {
        .frequency_hz = 250,           // 250 Hz control loop
        .callback = motor_tick,
        .user_data = &s_motor_ctx,
        .priority = 10                 // High priority
    };

    rx_err_t err = rx_cmt_init(k_cmt_channel_1, &config);
    if (err != k_rx_ok) {
        rx_log_error("MOTOR", "Failed to init CMT");
    }
}
```

See also

[rx_cmt_stop\(\)](#) Pause timer
[rx_cmt_start\(\)](#) Resume timer
[rx_cmt_deinit\(\)](#) Release channel

Since

Version 1.0.0

Initialize CMT channel for periodic interrupts.

Configures a CMT (Compare Match Timer) channel to fire a user callback at the requested frequency. Validates parameters, selects the optimal clock divider, enables the module clock, stops the timer for safe configuration, programs timer registers, configures the ICU interrupt routing, saves the callback, and starts the timer.

Algorithm steps:

1. Validate channel and config parameters via [internal_validate_cmt_init_params\(\)](#)
2. Obtain CMT channel register base via [internal_get_cmt_base\(\)](#)
3. Calculate optimal divider and CMCOR value via [internal_calculate_cmt_params\(\)](#)
4. Enable CMT module clock (clear MSTPCRB bit) via [internal_enable_cmt_module_clock\(\)](#)
5. Stop the timer to allow safe register writes via [rx_cmt_stop\(\)](#)
6. Program CMCR (divider + CMIE) and CMCOR via [internal_configure_cmt_timer_registers\(\)](#)
7. Configure ICU interrupt vector priority and enable via [internal_configure_cmt_interrupt\(\)](#)
8. Save callback pointer and mark channel initialized via [internal_save_cmt_callback\(\)](#)
9. Start the timer via [rx_cmt_start\(\)](#)

Clock divider selection: The driver iterates dividers /8, /32, /128, /512 and picks the first that produces a period fitting in 16 bits:

```
period = (PCLKB / divider) / frequency_hz
if (0 < period <= 65535): use this divider
```

Precondition

config must point to a valid `rx_cmt_config_t` structure
config->frequency_hz must be > 0 and $\leq \text{PCLKB} / 8$ (7.5 MHz at 60 MHz PCLKB)
channel must not be `k_cmt_channel_0`
System clocks must be initialized ($\text{PCLKB} = 60 \text{ MHz}$)

Postcondition

Timer running at requested frequency
config->callback registered and called from ISR at each compare match
`s_cmt_initialized[channel]` set to true
ICU interrupt for the channel enabled at specified priority

Note

Not thread-safe - call once per channel during system initialization
Callback executes in interrupt context; keep it short and non-blocking

Warning

CMT0 is reserved for ThreadX; do not use `k_cmt_channel_0`

Thread Safety:

Not thread-safe. Call once per channel during initialization before starting the RTOS scheduler or with interrupts disabled.

Performance:

- Execution time: $\sim 5 \text{ us}$ (mostly register writes)
- Stack usage: 48 bytes

Example:

```
static void my_timer_cb(void* user_data)
{
    // Called at 1 kHz from interrupt context
    (void)user_data;
    toggle_led();
}

const rx_cmt_config_t cfg = {
    .frequency_hz = 1000, // 1 kHz
    .priority     = 5,
    .callback     = my_timer_cb,
    .user_data    = nullptr,
};

rx_err_t err = rx_cmt_init(k_cmt_channel_1, &cfg);
if (err != k_rx_ok) {
    rx_log_error("APP", "CMT init failed");
}
```

Here is the call graph for this function:

8.73.6.6 rx'cmt'start()

```
rx_err_t rx_cmt_start (
    const rx_cmt_channel_t channel) [nodiscard]
```

Start CMT timer.

Starts the timer counter and interrupt generation. The timer is automatically started during [rx_cmt_init\(\)](#), so this function is only needed after calling [rx_cmt_stop\(\)](#) to resume operation.

Parameters

in	channel	CMT channel to start Valid range: k_cmt_channel_0 to k_cmt_channel_3
----	---------	--

Returns

`rx_err_t` Start status

Return values

<code>k_rx_ok</code>	Timer started successfully
<code>k_rx_err_invalid_arg</code>	Invalid channel number
<code>k_rx_err_invalid_state</code>	Channel not initialized
<code>k_rx_err_hw_error</code>	Hardware failed to start (CMSTR readback failed)

Precondition

Channel initialized via `rx_cmt_init()`

Postcondition

Timer counter incrementing

Interrupts generating at configured frequency

Note

Counter resumes from current value (not reset to 0).

Thread Safety:

Not thread-safe. Call from single thread or protect with mutex.

See also

`rx_cmt_stop()` Stop timer

`rx_cmt_init()` Initialize channel

Since

Version 1.0.0

Start CMT timer.

Sets the appropriate bit in the CMSTR0 or CMSTR1 register to start the CMT counter running. After setting the bit the register is read back to verify the hardware accepted the write. Channels 0/1 share CMSTR0; channels 2/3 share CMSTR1. Channels 0 and 1 use STR0/STR1 bits respectively, as do channels 2 and 3.

Precondition

channel must be initialized via `rx_cmt_init()`

channel must be in range [0, 3]

Postcondition

CMSTR bit for channel is set
Counter begins incrementing from its current value

Note

Usually called automatically by `rx_cmt_init()`; call explicitly only after `rx_cmt_stop()`
Performs a readback check to verify the hardware write succeeded

Thread Safety:

Not thread-safe; do not call concurrently with stop/deinit on the same channel.

Example:

```
// Pause then resume timer
rx_cmt_stop(k_cmt_channel_1);
// ... do critical work ...
rx_cmt_start(k_cmt_channel_1);
```

Here is the caller graph for this function:

8.73.6.7 rx_cmt_stop()

```

rx_err_t rx_cmt_stop (
    const rx_cmt_channel_t channel) [nodiscard]

```

Stop CMT timer.

Stops the timer counter and interrupt generation. Counter value is preserved and can be read with [rx_cmt_get_count\(\)](#). Use [rx_cmt_start\(\)](#) to resume.

Parameters

in	channel	CMT channel to stop Valid range: <code>k_cmt_channel_0</code> to <code>k_cmt_channel_3</code>
----	---------	---

Returns

`rx_err_t` Stop status

Return values

<code>k_rx_ok</code>	Timer stopped successfully
<code>k_rx_err_invalid_arg</code>	Invalid channel number
<code>k_rx_err_hw_error</code>	Hardware failed to stop (CMSTR readback failed)

Postcondition

Timer counter frozen at current value

No further interrupts until [rx_cmt_start\(\)](#) called

Note

Counter value preserved. Call [rx_cmt_start\(\)](#) to resume counting.

Thread Safety:

Not thread-safe. Call from single thread or protect with mutex.

See also

[rx_cmt_start\(\)](#) Resume timer

[rx_cmt_get_count\(\)](#) Read frozen counter value

Since

Version 1.0.0

Stop CMT timer.

Clears the appropriate bit in CMSTR0 or CMSTR1 to halt the CMT counter. After clearing the bit the register is read back to verify the hardware accepted the write. The channel remains initialized; call [rx_cmt_start\(\)](#) to resume counting.

Note that [rx_cmt_stop\(\)](#) does NOT require the channel to be initialized (`s_cmt_initialized` check is omitted intentionally so that [rx_cmt_init\(\)](#) can call it safely before marking the channel as initialized).

Precondition

channel must be in range [0, 3]

Interrupts may still fire if one is already pending when stop is called

Postcondition

CMSTR bit for channel is cleared

Counter stops incrementing (current CMCNT value preserved)

Note

Does not clear the initialized flag - channel can be restarted

Called by `rx_cmt_init()` before programming registers (safe on uninitialized channel)

Thread Safety:

Not thread-safe; do not call concurrently with start/init/deinit on the same channel.

Example:

```
// Temporarily suspend timer
rx_cmt_stop(k_cmt_channel_2);
reconfigure_something();
rx_cmt_start(k_cmt_channel_2);
```

00001 /**
00002  * @file rx_cmt.h
00003  * @brief CMT (Compare Match Timer) Driver API for RX72N - Periodic Interrupt Generation
00004  *
00005  * @details
00006  * # Overview
00007  *
00008  * The Compare Match Timer (CMT) driver provides periodic interrupt generation for the
00009  * RX72N microcontroller. CMT is used for system timing, motor control loops, and
00010  * other periodic tasks requiring precise timing.
00011  *
00012  * ## CMT Hardware Overview
00013  *
00014  * The RX72N has **4 CMT channels** organized in 2 units:
00015  *
00016  * @dot
00017  * digraph cmt_architecture {
00018  *     rankdir=TB;
00019  *     node [shape=box, style=rounded];
00020  *
00021  *     subgraph cluster_unit0 {
00022  *         label="CMT Unit 0";
00023  *         style=filled;
00024  *         color=lightblue;
00025  *         cmt0 [label="CMT0\n(ThreadX Tick)", fillcolor=yellow, style=filled];
00026  *         cmt1 [label="CMT1\n(Motor Control)", fillcolor=lightgreen, style=filled];
00027  *     }
00028  *
00029  *     subgraph cluster_unit1 {
00030  *         label="CMT Unit 1";

```

```

00031 * style=filled;
00032 * color=lightblue;
00033 * cmt2 [label="CMT2\n(Available)"];
00034 * cmt3 [label="CMT3\n(Available)"];
00035 * }
00036 *
00037 * pclk [label="PCLK\n60 MHz", shape=ellipse];
00038 * icu [label="ICU\n(Interrupts)", shape=ellipse];
00039 *
00040 * pclk -> cmt0;
00041 * pclk -> cmt1;
00042 * pclk -> cmt2;
00043 * pclk -> cmt3;
00044 *
00045 * cmt0 -> icu [label="CMT0"];
00046 * cmt1 -> icu [label="CMT1"];
00047 * cmt2 -> icu [label="CMT2"];
00048 * cmt3 -> icu [label="CMT3"];
00049 * }
00050 * @enddot
00051 *
00052 * ## Channel Allocation
00053 *
00054 * | Channel | Usage | Frequency | Description |
00055 * |-----|-----|-----|-----|
00056 * | **CMT0** | ThreadX | 100 Hz | System tick (RESERVED) |
00057 * | **CMT1** | Motor | 100-1000 Hz | Motor control loop |
00058 * | **CMT2** | Available | User-defined | General purpose |
00059 * | **CMT3** | Available | User-defined | General purpose |
00060 *
00061 * @warning **CMT0 is reserved** for ThreadX system tick. Do not use CMT0 with this API.
00062 *
00063 * ## CMT Operation Principle
00064 *
00065 * @msc
00066 * width=600;
00067 * Counter, CMCOR, Interrupt;
00068 *
00069 * Counter box Counter [label="16-bit up counter\nStarts at 0"];
00070 * Counter -> Counter [label="Count up"];
00071 * Counter => CMCOR [label="CMCNT == CMCOR"];
00072 * CMCOR box CMCOR [label="Compare match!\nCMCNT = 0"];
00073 * CMCOR => Interrupt [label="CMIn interrupt"];
00074 * Interrupt » Counter [label="Continue counting"];
00075 * @endmsc
00076 *
00077 * ## Clock Divider Selection
00078 *
00079 * | Divider | CKS Value | Clock Rate | Min Freq | Max Freq | Notes |
00080 * |-----|-----|-----|-----|-----|-----|
00081 * | PCLKB/8 | 0b00 | 7.5 MHz | 115 Hz | 7.5 MHz | High resolution |
00082 * | PCLKB/32 | 0b01 | 1.875 MHz | 29 Hz | 1.875 MHz | Medium resolution |
00083 * | PCLKB/128 | 0b10 | 468.75 kHz | 7.2 Hz | 468 kHz | **Recommended** |
00084 * | PCLKB/512 | 0b11 | 117.2 kHz | 1.8 Hz | 117 kHz | Low frequency |
00085 *
00086 * **Calculation example for 250 Hz motor control loop:**
00087 * ```
00088 * PCLKB = 60 MHz
00089 * Divider = 128 -> Counter clock = 468.75 kHz
00090 * Period = 468750 / 250 = 1875 counts
00091 * ```
00092 *
00093 * ## Memory-Mapped Register Layout
00094 *
00095 * | Register | Offset | Description |
00096 * |-----|-----|-----|
00097 * | CMSTR0 | 0x0000 | Start register for CMT0/CMT1 |
00098 * | CMSTR1 | 0x0010 | Start register for CMT2/CMT3 |
00099 * | CMCRn | +0x00 | Control register (clock select, interrupt enable) |
00100 * | CMCNtn | +0x02 | 16-bit counter register |
00101 * | CMCORn | +0x04 | 16-bit compare match register |
00102 *
00103 * ## NASA Power of 10 Compliance
00104 *
00105 * | Rule | Status | Implementation |
00106 * |-----|-----|-----|
00107 * | **Rule 1: Control flow** | [PASS] | No goto, setjmp, or recursion |
00108 * | **Rule 2: Loop bounds** | [PASS] | Bounded divider search (4 iterations max) |
00109 * | **Rule 3: No heap** | [PASS] | Static callback arrays only |
00110 * | **Rule 4: Function length** | [PASS] | All functions under 60 lines |
00111 * | **Rule 5: Assertions** | [PASS] | Parameter validation in all functions |
00112 * | **Rule 6: Data scope** | [PASS] | File-scope static with s_ prefix |
00113 * | **Rule 7: Return checks** | [PASS] | All internal calls checked |
00114 * | **Rule 8: Preprocessor** | [PASS] | C23 typed enums for all constants |
00115 * | **Rule 9: Pointers** | [PASS] | Single-level only (callback + user_data) |
00116 * | **Rule 10: Warnings** | [PASS] | -Wall -Wextra -Werror clean |
00117 *

```

```

00118 * ## SOLID Principles
00119 *
00120 * | Principle | Application |
00121 * |-----|-----|
00122 * **S - Single Responsibility** | CMT driver handles only compare match timers |
00123 * **O - Open/Closed** | Extended via callback registration |
00124 * **L - Liskov Substitution** | All channels use identical API |
00125 * **I - Interface Segregation** | Simple 5-function API |
00126 * **D - Dependency Inversion** | Callback injection for user code |
00127 *
00128 * ## Module Dependencies
00129 *

00204  * @brief CMT interrupt callback function type
00205  *
00206  * @details
00207  * User-provided function called from CMT interrupt context on each compare match.
00208  * Keep callbacks short and non-blocking to avoid interrupt latency issues.
00209  *
00210  * ## Callback Execution Context
00211  *
00212  * - **Interrupt level:** IPL equal to configured priority
00213  * - **Stack:** Interrupt stack (not task stack)
00214  * - **Timing:** Called every compare match period
00215  * - **Duration:** Keep under 10 us for real-time performance
00216  *
00217  * ## Allowed Operations
00218  *
00219  * | Operation | Allowed | Notes |
00220  * |-----|-----|-----|
00221  * | Set flag | [PASS] | Signal task to process |
00222  * | Write GPIO | [PASS] | Toggle debug pin |
00223  * | Queue message | [PASS] | Use ThreadX queue |
00224  * | Blocking call | [FAIL] | Causes interrupt overrun |
00225  * | Memory allocation | [FAIL] | NASA Rule 3 violation |
00226  * | Long computation | [FAIL] | Delays other interrupts |
00227  *
00228  * @param[in] user_data User data pointer provided during rx_cmt_init()
00229  * May be NULL if no user data needed.
00230  *
00231  * @note Callback executes in interrupt context. Keep it fast!
00232  * @warning Do not call blocking functions from callback.
00233  * @warning Do not disable interrupts for extended periods.
00234  *
00235  * @par Example:
00236  * @code{.c}
00237  * static volatile bool s_motor_tick = false;
00238  *
00239  * void motor_timer_callback(void* user_data) {
00240  *     (void)user_data;
00241  *     s_motor_tick = true; // Signal motor task
00242  * }
00243  * @endcode
00244  *
00245  * @see rx_cmt_config_t::callback Callback registration
00246  *
00247  * @since Version 1.0.0
00248  */
00249 typedef void (*rx_cmt_callback_t)(void* user_data);
00250
00251 /**
00252  * @struct rx_cmt_config_t
00253  * @brief CMT channel configuration structure
00254  *
00255  * @details
00256  * Configuration parameters for initializing a CMT channel. All fields must be
00257  * set before calling rx_cmt_init().
00258  *
00259  * ## Memory Layout
00260  *
00261  * | Offset | Field | Size | Description |
00262  * |-----|-----|-----|-----|
00263  * | 0x00 | frequency_hz | 4 | Target interrupt frequency |
00264  * | 0x04 | callback | 4 | Interrupt callback pointer |
00265  * | 0x08 | user_data | 4 | User data for callback |
00266  * | 0x0C | priority | 1 | Interrupt priority level |
00267  *
00268  * **Total size:** 13 bytes (16 with padding)
00269  *
00270  * ## Frequency Calculation
00271  *
00272  * The driver automatically selects the best clock divider for the requested
00273  * frequency. Valid range depends on PCLKB (60 MHz):
00274  * - Minimum: ~1.8 Hz (with /512 divider)
00275  * - Maximum: ~7.5 MHz (with /8 divider)
00276  *
00277  * ## Example Configuration
00278  *
00279  * @code{.c}
00280  * rx_cmt_config_t config = {
00281  *     .frequency_hz = 250, // 250 Hz motor control
00282  *     .callback = motor_tick_handler,
00283  *     .user_data = &motor_context,
00284  *     .priority = 8 // Medium priority
00285  * };
00286  * @endcode
00287  *
00288  * @see rx_cmt_init() Uses this configuration
00289  */

```

```

00290 * @since Version 1.0.0
00291 */

8.75 libs/rx_hal/inc/rx_doc.h File Reference

RX72N DOC (Data Operation Circuit) HAL Public API.

```

#include <stdbool.h>
#include <stdint.h>
#include "rx_err.h"

```

Include dependency graph for rx_doc.h:

This graph shows which files directly or indirectly include this file:

Enumerations

- enum `rx_doc_mode_t`: `uint8_t` { `k_rx_doc_mode_compare` = 0, `k_rx_doc_mode_compare_neq` = 1, `k_rx_doc_mode_add` = 2, `k_rx_doc_mode_subtract` = 3 }
Selects the DOC operating mode.

Functions

- `rx_err_t rx_doc_init(rx_doc_mode_t mode)`
Initialize DOC in the selected operating mode.
- `rx_err_t rx_doc_set_reference(uint16_t reference)`
Load the DOC reference value (DODIR) used for the next operation.
- `rx_err_t rx_doc_compare(uint16_t value, bool *matched)`
Execute a compare operation against the loaded reference.
- `rx_err_t rx_doc_add(uint16_t addend, uint16_t *sum, bool *overflow)`
Execute a 16-bit add using the DOC.
- `rx_err_t rx_doc_subtract(uint16_t subtrahend, uint16_t *difference, bool *borrow)`
Execute a 16-bit subtract using the DOC.
- `rx_err_t rx_doc_deinit(void)`
Deinitialize DOC and gate its clock.

8.75.1 Detailed Description

RX72N DOC (Data Operation Circuit) HAL Public API.

Higher-level driver API for the RX72N Data Operation Circuit. The DOC is a fixed-function 16-bit compute accelerator supporting four operations:

- Compare equal (`k_rx_doc_mode_compare`): flag set when `DODIR == DODSR`
- Compare not-equal (`k_rx_doc_mode_compare_neq`): flag set when `DODIR != DODSR`
- Add (`k_rx_doc_mode_add`): `DODSR += DODIR`, flag on carry past `0xFFFF`
- Subtract (`k_rx_doc_mode_subtract`): `DODSR -= DODIR`, flag on borrow below `0x0000`

8.75.1.1 STAR Use Case

Low-cost integrity check on small safety-critical values (PID gains, shared telemetry words, firmware identifiers). Significantly cheaper than a CRC when the payload is only 16 bits.

8.75.1.2 Usage Pattern

```
// 1. Initialize in compare-equal mode
rx_err_t err = rx_doc_init(k_rx_doc_mode_compare);

// 2. Load the expected reference value
err = rx_doc_set_reference(0xCAFE);

// 3. Run the operation
bool matched = false;
err = rx_doc_compare(0xCAFE, &matched); // matched = true

// 4. Later, switch modes for a running-sum check
rx_doc_init(k_rx_doc_mode_add);
rx_doc_set_reference(0x0000);
uint16_t sum = 0;
bool overflow = false;
rx_doc_add(0x1234, &sum, &overflow); // sum = 0x1234, overflow = false

// 5. Power down
rx_doc_deinit();
```

8.75.1.3 Thread Safety

The DOC is a single-instance peripheral. All functions in this API are not thread-safe; callers must serialize access via an RTOS mutex or by confining DOC use to a single task.

NASA Power of 10 Compliance

- Rule 1: No goto / setjmp / recursion
- Rule 2: No unbounded loops
- Rule 3: No dynamic allocation
- Rule 4: All functions ≤ 60 lines
- Rule 5: Minimum 2 validation checks per function
- Rule 6: File-scope state is static, narrowest possible
- Rule 7: All return values checked or cast to void
- Rule 8: C23 typed enums for all constants
- Rule 9: Single-level pointers
- Rule 10: Compiles with -Wall -Wextra -Werror

8.75.2 Enumeration Type Documentation

8.75.2.1 rx'doc'mode't

enum [rx_doc_mode_t](#) : uint8_t

Selects the DOC operating mode.

Determines which DOC hardware mode (OMS + DCSEL) is configured by [rx_doc_init\(\)](#).

Mode value	OMS	DCSEL	Hardware behavior
k_rx_doc_mode_compare	00	1	DOPCF set when DODIR == DODSR
k_rx_doc_mode_compare_neq	00	0	DOPCF set when DODIR != DODSR
k_rx_doc_mode_add	01	x	DODSR += DODIR; DOPCF on carry
k_rx_doc_mode_subtract	10	x	DODSR -= DODIR; DOPCF on borrow

Since

Version 1.0.0

Enumerator

k_rx_doc_mode_compare	Compare equal (flag on match)
k_rx_doc_mode_compare_neq	Compare not-equal (flag on mismatch)
k_rx_doc_mode_add	16-bit addition
k_rx_doc_mode_subtract	16-bit subtraction

Definition at line 104 of file [rx_doc.h](#).

```

00104     : uint8_t {
00105   k_rx_doc_mode_compare    = 0, /**< Compare equal (flag on match)    */
00106   k_rx_doc_mode_compare_neq = 1, /**< Compare not-equal (flag on mismatch) */
00107   k_rx_doc_mode_add        = 2, /**< 16-bit addition                */
00108   k_rx_doc_mode_subtract   = 3, /**< 16-bit subtraction            */
00109 } rx_doc_mode_t;
```

8.75.3 Function Documentation

8.75.3.1 rx'doc'add()

```

rx_err_t rx_doc_add (
    uint16_t addend,
    uint16_t * sum,
    bool * overflow)
```

Execute a 16-bit add using the DOC.

Writes addend to DODSR, which triggers DODSR = DODSR_before + DODIR. Reads back DODSR for the sum, reads DOPCF to detect carry (sum overflowed past 0xFFFF), then clears DOPCF.

To chain adds (running sum), call [rx_doc_set_reference\(\)](#) once with the initial accumulator and then call [rx_doc_add\(\)](#) repeatedly; each call uses DODIR as the first operand and addend as the second.

Parameters

in	addend	16-bit value to add to the reference
out	sum	16-bit result (DODSR after the operation)
out	overflow	true if the add carried past 0xFFFF, false otherwise

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Success
<code>k_rx_err_null_ptr</code>	sum or overflow is nullptr
<code>k_rx_err_not_initialized</code>	rx_doc_init() has not been called
<code>k_rx_err_invalid_state</code>	Driver is initialized but not in add mode

Precondition

Driver initialized in `k_rx_doc_mode_add`

Postcondition

`*sum == (DODIR + addend) mod 65536`
`*overflow` reflects DOPCF after the operation
DOPCF is cleared

Since

Version 1.0.0

Execute a 16-bit add using the DOC.

Writes the addend into DODSR; the DOC then computes `sum = DODIR + addend` with overflow flagged in DOPCF. Reads the result back through DODSR (post-operation register) and reports the overflow flag, then clears DOPCF before return.

Note

Not thread-safe. Serialize access to the global DOC peripheral.

Definition at line 333 of file [rx_doc.c](#).

```

00334 {
00335     RX_CHECK_NULL_PTR(sum, s_tag, "rx_doc_add: sum is NULL");
00336     RX_CHECK_NULL_PTR(overflow, s_tag, "rx_doc_add: overflow is NULL");
00337
00338     if (s_doc_init_state != k_doc_initialized) {
00339         rx_log_error(s_tag, "rx_doc_add: driver not initialized");
00340         return k_rx_err_not_initialized;
00341     }
00342     if (s_doc_mode != k_rx_doc_mode_add) {
00343         rx_log_error(s_tag, "rx_doc_add: driver not in add mode");
00344         return k_rx_err_invalid_state;

```

```

00345 }
00346
00347 doc()->dodsr = addend;
00348 *sum        = doc()->dodsr;
00349 *overflow    = internal_read_dopcf();
00350 internal_clear_dopcf();
00351 return k_rx_ok;
00352 }

```

References [doc\(\)](#), [rx_doc_regs_t::dodsr](#), [internal_clear_dopcf\(\)](#), [internal_read_dopcf\(\)](#), [k_doc_initialized](#), [k_rx_doc_mode_add](#), [s_doc_init_state](#), [s_doc_mode](#), and [s_tag](#).

Here is the call graph for this function:

8.75.3.2 rx`doc`compare()

```

rx_err_t rx_doc_compare (
    uint16_t value,
    bool * matched)

```

Execute a compare operation against the loaded reference.

Writes value to DODSR, which triggers the DOC to evaluate the configured compare condition. Reads DOPCF to report whether the condition fired, then clears DOPCF.

Interpretation depends on the mode selected at init time:

- `k_rx_doc_mode_compare`: `*matched = true` when `DODIR == value`
- `k_rx_doc_mode_compare_neq`: `*matched = true` when `DODIR != value`

Parameters

in	value	16-bit value to compare against the DODIR reference
out	matched	Set to true if the compare condition fired, false otherwise

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Success
<code>k_rx_err_null_ptr</code>	matched is nullptr

k_rx_err_not_initialized	rx_doc_init() has not been called
k_rx_err_invalid_state	Driver is initialized but not in a compare mode

Precondition

Driver initialized in a compare mode (compare or compare_neq)
DODIR loaded via [rx_doc_set_reference\(\)](#)

Postcondition

*matched reflects the configured condition
DOPCF is cleared

Since

Version 1.0.0

Execute a compare operation against the loaded reference.

Writes value into DODSR, latches the comparator flag (DOPCF), and reports whether the configured compare condition is satisfied. In k_rx_doc_mode_compare the flag is set on equality; in k_rx_doc_mode_compare_neq the flag is set on inequality. The comparator flag is cleared internally before return so successive compares are independent.

Note

Not thread-safe. Serialize access to the global DOC peripheral.

Definition at line 303 of file [rx_doc.c](#).

```

00304 {
00305     RX_CHECK_NULL_PTR(matched, s_tag, "rx_doc_compare: matched is NULL");
00306
00307     if (s_doc_init_state != k_doc_initialized) {
00308         rx_log_error(s_tag, "rx_doc_compare: driver not initialized");
00309         return k_rx_err_not_initialized;
00310     }
00311     if ((s_doc_mode != k_rx_doc_mode_compare) && (s_doc_mode != k_rx_doc_mode_compare_neq)) {
00312         rx_log_error(s_tag, "rx_doc_compare: driver not in a compare mode");
00313         return k_rx_err_invalid_state;
00314     }
00315
00316     doc()->dodsr = value;
00317     *matched = internal_read_dopcf();
00318     internal_clear_dopcf();
00319     return k_rx_ok;
00320 }

```

References [doc\(\)](#), [rx_doc_regs_t::dodsr](#), [internal_clear_dopcf\(\)](#), [internal_read_dopcf\(\)](#), [k_doc_initialized](#), [k_rx_doc_mode_compare](#), [k_rx_doc_mode_compare_neq](#), [s_doc_init_state](#), [s_doc_mode](#), and [s_tag](#).

Here is the call graph for this function:

8.75.3.3 rx'doc'deinit()

```
rx_err_t rx_doc_deinit (
    void )
```

Deinitialize DOC and gate its clock.

Clears DOCR (disables DOPCIE, deselects the mode), sets MSTPCRB.MSTPB6 under PRCR.PRC1 unlock to stop the DOC module, and marks the driver uninitialized.

Safe to call without a prior [rx_doc_init\(\)](#) (returns k_rx_ok and does nothing).

Returns

rx_err_t Error code

Return values

k_rx_ok	Always
---------	--------

Postcondition

DOCR == 0
MSTPCRB.MSTPB6 == 1 (DOC module stopped)
Driver is marked uninitialized

Since

Version 1.0.0

Deinitialize DOC and gate its clock.

Idempotent: returns k_rx_ok immediately if the driver was not initialized. Otherwise clears DOC->DOCR (mode register), disables the DOC module clock through [internal_disable_doc_clock\(\)](#), and marks the driver as uninitialized.

Note

Not thread-safe. Serialize access to the global DOC peripheral.

Definition at line 397 of file [rx_doc.c](#).

```
00398 {
00399     if (s_doc_init_state != k_doc_initialized) {
00400         return k_rx_ok;
00401     }
00402
00403     doc()->docr = 0U;
00404     internal_disable_doc_clock();
00405
00406     s_doc_init_state = k_doc_not_initialized;
00407     return k_rx_ok;
00408 }
```

References [doc\(\)](#), [rx_doc_regs_t::docr](#), [internal_disable_doc_clock\(\)](#), [k_doc_initialized](#), [k_doc_not_initialized](#), and [s_doc_init_state](#).

Here is the call graph for this function:

8.75.3.4 rx_doc_init()

```
rx_err_t rx_doc_init (
    rx_doc_mode_t mode)
```

Initialize DOC in the selected operating mode.

Powers on the DOC (clears MSTPCRB.MSTPB6 under PRCR.PRC1 unlock), then configures DOCR with the requested operation mode, clears any stale DOPCF, and marks the driver initialized.

Subsequent operations expect the driver to remain in this mode until [rx_doc_init\(\)](#) is called again with a different mode (re-init is allowed and is the supported way to switch modes).

Parameters

in	mode	Operating mode to configure
----	------	-----------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Success
k_rx_err_invalid_arg	mode is not a valid rx_doc_mode_t value

Precondition

PRCR accessor ([prcr_reg\(\)](#)) is addressable
MSTPCRB is writable once PRCR.PRC1 is unlocked

Postcondition

DOC module stop bit cleared (MSTPCRB.MSTPB6 = 0)
DOCR configured for the requested mode, DOPCIE = 0, DOPCF cleared
Driver is marked initialized

Note

Not thread-safe. Caller must serialize DOC access.

See also

[rx_doc_deinit\(\)](#)

Since

Version 1.0.0

Definition at line 250 of file [rx_doc.c](#).

```

00251 {
00252     uint8_t      mode_bits = 0U;
00253     const rx_err_t err      = internal_docr_for_mode(mode, &mode_bits);
00254     if (err != k_rx_ok) {
00255         rx_log_error(s_tag, "rx_doc_init: invalid mode");
00256         return err;
00257     }
00258
00259     internal_enable_doc_clock();
00260     doc()->docr = (uint8_t)(mode_bits | k_doc_dopcfcl_clear);
00261
00262     s_doc_mode      = mode;
00263     s_doc_init_state = k_doc_initialized;
00264     return k_rx_ok;
00265 }
```

Here is the call graph for this function:

8.75.3.5 rx_doc_set_reference()

```

rx_err_t rx_doc_set_reference (
    uint16_t reference)
```

Load the DOC reference value (DODIR) used for the next operation.

Parameters

in	reference	16-bit reference / operand value
----	-----------	----------------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Success
---------	---------

k_rx_err_not_initialized	rx_doc_init() has not been called
--------------------------	---

Precondition

Driver must be initialized via [rx_doc_init\(\)](#)

Postcondition

DODIR == reference

Note

Writing DODIR does not trigger the operation – only writing DODSR does.

Since

Version 1.0.0

Load the DOC reference value (DODIR) used for the next operation.

Writes the supplied 16-bit reference value into the Data Operation Circuit Input register (DODIR) that subsequent [rx_doc_compare\(\)](#) / [rx_doc_add\(\)](#) / [rx_doc_subtract\(\)](#) calls operate against. Validates driver init state but does not validate or constrain the value range (any 16-bit value is meaningful in compare/add/subtract modes).

Note

Not thread-safe. The DOC peripheral is global; serialize access at the application layer.

Definition at line 280 of file [rx_doc.c](#).

```
00281 {
00282   RX_VALIDATE_INIT(s_doc_init_state == k_doc_initialized,
00283                   s_tag,
00284                   "rx_doc_set_reference: driver not initialized");
00285
00286   doc()->dodir = reference;
00287   return k_rx_ok;
00288 }
```

References [doc\(\)](#), [rx_doc_regs_t::dodir](#), [k_doc_initialized](#), [s_doc_init_state](#), and [s_tag](#).

Here is the call graph for this function:

8.75.3.6 rx'doc'subtract()

```
rx_err_t rx_doc_subtract (
    uint16_t subtrahend,
    uint16_t * difference,
    bool * borrow)
```

Execute a 16-bit subtract using the DOC.

Writes subtrahend to DODSR, which triggers $DODSR = DODSR_before - DODIR$. Reads back DODSR for the difference, reads DOPCF to detect borrow (difference would have gone below 0x0000), then clears DOPCF.

Parameters

in	subtrahend	16-bit value to subtract from the reference
out	difference	16-bit result (DODSR after the operation)
out	borrow	true if the subtract borrowed below 0x0000, false otherwise

Returns

rx_err_t Error code

Return values

k_rx_ok	Success
k_rx_err_null_ptr	difference or borrow is nullptr
k_rx_err_not_initialized	rx_doc_init() has not been called
k_rx_err_invalid_state	Driver is initialized but not in subtract mode

Precondition

Driver initialized in k_rx_doc_mode_subtract

Postcondition

*difference == $(DODIR - subtrahend) \bmod 65536$

*borrow reflects DOPCF after the operation

DOPCF is cleared

Since

Version 1.0.0

Execute a 16-bit subtract using the DOC.

Writes subtrahend into DODSR; the DOC computes $difference = DODIR - subtrahend$ with borrow flagged in DOPCF. Reads the result back through DODSR and reports the borrow flag, then clears DOPCF before return.

Note

Not thread-safe. Serialize access to the global DOC peripheral.

Definition at line 365 of file [rx_doc.c](#).

```

00366 {
00367     RX_CHECK_NULL_PTR(difference, s_tag, "rx_doc_subtract: difference is NULL");

8.76 rx_doc.h

[Go to the documentation of this file.](#)

```

00001 /**
00002  * @file rx_doc.h
00003  * @brief RX72N DOC (Data Operation Circuit) HAL Public API
00004  *
00005  * @details
00006  * Higher-level driver API for the RX72N Data Operation Circuit. The DOC is a
00007  * fixed-function 16-bit compute accelerator supporting four operations:
00008  *
00009  * - **Compare equal** (k_rx_doc_mode_compare): flag set when DODIR == DODSR
00010  * - **Compare not-equal** (k_rx_doc_mode_compare_neq): flag set when DODIR != DODSR
00011  * - **Add** (k_rx_doc_mode_add): DODSR += DODIR, flag on carry past 0xFFFF
00012  * - **Subtract** (k_rx_doc_mode_subtract): DODSR -= DODIR, flag on borrow below 0x0000
00013  *
00014  * ## STAR Use Case
00015  *
00016  * Low-cost integrity check on small safety-critical values (PID gains, shared
00017  * telemetry words, firmware identifiers). Significantly cheaper than a CRC
00018  * when the payload is only 16 bits.
00019  *
00020  * ## Usage Pattern
00021  *
00022  * @code{.c}
00023  * // 1. Initialize in compare-equal mode
00024  * rx_err_t err = rx_doc_init(k_rx_doc_mode_compare);
00025  *
00026  * // 2. Load the expected reference value
00027  * err = rx_doc_set_reference(0xCAFE);
00028  *
00029  * // 3. Run the operation
00030  * bool matched = false;
00031  * err = rx_doc_compare(0xCAFE, &matched); // matched = true

```

```

00032 *
00033 * // 4. Later, switch modes for a running-sum check
00034 * rx_doc_init(k_rx_doc_mode_add);
00035 * rx_doc_set_reference(0x0000);
00036 * uint16_t sum = 0;
00037 * bool overflow = false;
00038 * rx_doc_add(0x1234, &sum, &overflow);    // sum = 0x1234, overflow = false
00039 *
00040 * // 5. Power down
00041 * rx_doc_deinit();
00042 * @endcode
00043 *
00044 * ## Thread Safety
00045 *
00046 * The DOC is a single-instance peripheral. All functions in this API are
00047 * **not** thread-safe; callers must serialize access via an RTOS mutex or by
00048 * confining DOC use to a single task.
00049 *
00050 * @par NASA Power of 10 Compliance
00051 * - Rule 1: No goto / setjmp / recursion
00052 * - Rule 2: No unbounded loops
00053 * - Rule 3: No dynamic allocation

This graph shows which files directly or indirectly include this file:

Data Structures

- struct [rx_eccram_status_t](#)
Snapshot of ECCRAM error flags and captured addresses.

Typedefs

- typedef void(* [rx_eccram_on_1bit_fn_t](#)) (uintptr_t addr, void *ctx)
1-bit error ISR callback signature
- typedef void(* [rx_eccram_on_2bit_fn_t](#)) (uintptr_t addr, void *ctx)
2-bit error ISR callback signature

Enumerations

- enum [rx_eccram_mode_t](#) : uint8_t { [k_eccram_mode_disabled](#) = 0 , [k_eccram_mode_correct_only](#) = 1 , [k_eccram_mode_correct_and_detect](#) = 2 , [k_eccram_mode_detect_only](#) = 3 }
ECCRAM operating modes exposed to application code.

Functions

- `rx_err_t rx_eccram_init (rx_eccram_mode_t mode)`
Initialise ECCRAM in the requested operating mode.
- `rx_err_t rx_eccram_get_error_status (rx_eccram_status_t *out)`
Read a snapshot of ECCRAM error status and captured addresses.
- `rx_err_t rx_eccram_clear_errors (void)`
Clear 1-bit and 2-bit error status flags.
- `rx_err_t rx_eccram_register_error_isr (rx_eccram_on_1bit_fn_t on_1bit, rx_eccram_on_2bit_fn_t on_2bit, void *ctx)`
Register user callbacks for ECC error ISRs.
- `uintptr_t rx_eccram_region_start (void)`
Return the inclusive start address of the ECCRAM data region.
- `uintptr_t rx_eccram_region_end (void)`
Return the inclusive end address of the ECCRAM data region.

8.77.1 Detailed Description

ECC-Protected RAM (ECCRAM) Driver API.

Public driver interface for the 32 KB ECC-protected RAM region on the RX72N. Provides mode configuration, error-status readout, error clearing, ISR registration for 1-bit/2-bit errors, and region introspection (start/end addresses for use by linker scripts).

STAR Use Case

Bit-flip-resistant storage for safety-critical mutable state:

- Motor PID integrator accumulators
- Last-good encoder counts
- nanopb frame sequence numbers
- IWDT kick counter
- `shared_data_t` handoff between `motor_control_task` and `comm_task`

Single-bit errors are silently corrected by hardware; double-bit errors trigger the registered `on_2bit` handler, which captures the failing address and typically e-stops the system instead of acting on garbage.

Initialization Order

1. Call `rx_eccram_init(k_eccram_mode_correct_and_detect)` during `hardware_init` before any code places data in ECCRAM.
2. The driver clears `MSTPCRC.MSTPC6`, enables ECC generation without error checking, zeroes the entire 32 KB region with 32-bit stores so every ECC syndrome matches its data, then switches to the requested check mode.
3. Call `rx_eccram_register_error_isr()` to install application handlers (optional – the driver installs safe defaults).

Linker Integration

The driver provides `rx_eccram_region_start()` and `rx_eccram_region_end()` so linker scripts can place a dedicated `.eccram` output section between these addresses. See `star-rx72n-firmware/linker.lds`.

8.77.2 Data Structure Documentation

8.77.2.1 struct rx_eccram_status_t

Snapshot of ECCRAM error flags and captured addresses.

Returned by [rx_eccram_get_error_status\(\)](#) so callers can introspect ECC health without touching registers directly.

Invariant

one_bit_addr is meaningful only when one_bit_error is true

two_bit_addr is meaningful only when two_bit_error is true

See also

[rx_eccram_get_error_status\(\)](#)

Since

Version 1.0.0

Definition at line 103 of file [rx_eccram.h](#).

Collaboration diagram for rx_eccram_status_t:

Data Fields

uintptr_t	one_bit_addr	Captured address of last 1-bit error (from ECCRAM1ECAD).
bool	one_bit_error	true if ECCRAM1STS.ECC1ERR is set
uintptr_t	two_bit_addr	Captured address of last 2-bit error (from ECCRAM2ECAD).
bool	two_bit_error	true if ECCRAM2STS.ECC2ERR is set

8.77.3 Typedef Documentation

8.77.3.1 rx_eccram_on_1bit_fn_t

```
typedef void(* rx_eccram_on_1bit_fn_t) (uintptr_t addr, void *ctx)
```

1-bit error ISR callback signature

Parameters

in	addr	Captured failing address (from ECCRAM1ECAD)
in	ctx	Opaque context pointer supplied at registration

Note

Invoked from ISR context. Keep it short; log and return.

Since

Version 1.0.0

Definition at line 123 of file [rx_eccram.h](#).

8.77.3.2 rx_eccram_on_2bit_fn_t

```
typedef void(* rx_eccram_on_2bit_fn_t) (uintptr_t addr, void *ctx)
```

2-bit error ISR callback signature

Parameters

in	addr	Captured failing address (from ECCRAM2ECAD)
in	ctx	Opaque context pointer supplied at registration

Note

Invoked from ISR context. Typical implementation triggers e-stop via `shared_data` rather than continuing.

Since

Version 1.0.0

Definition at line 135 of file [rx_eccram.h](#).

8.77.4 Enumeration Type Documentation

8.77.4.1 rx_eccram_mode_t

```
enum rx_eccram_mode_t : uint8_t
```

ECCRAM operating modes exposed to application code.

Maps the raw hardware ECCRAMMODE field (RX72N HW Manual Ch60, section 60.2.9, page 2981) into the four behaviours the application actually cares about. The "detect only" configuration is emulated by installing a 1-bit handler that treats any 1-bit event as a fault rather than a silent correction – the RX72N hardware always corrects 1-bit errors on the data delivered to the CPU when ECC is enabled.

RX72N HW Manual Chapter 60, section 60.2.9, page 2981

Since

Version 1.0.0

Enumerator

k_eccram_mode_disabled	ECC disabled – contents are unchecked (debug/test only).
k_eccram_mode_correct_only	1-bit correction only – 2-bit errors go undetected
k_eccram_mode_correct_and_detect	1-bit correction + 2-bit detection (recommended default)

k_eccram_mode_detect_only	Detect-only: surface both 1-bit and 2-bit errors via ISRs.
---------------------------	--

Definition at line 77 of file [rx_eccram.h](#).

```

00077      : uint8_t {
00078      /** @brief ECC disabled -- contents are unchecked (debug/test only) */
00079      k_eccram_mode_disabled = 0,
00080      /** @brief 1-bit correction only -- 2-bit errors go undetected */
00081      k_eccram_mode_correct_only = 1,
00082      /** @brief 1-bit correction + 2-bit detection (recommended default) */
00083      k_eccram_mode_correct_and_detect = 2,
00084      /** @brief Detect-only: surface both 1-bit and 2-bit errors via ISRs */
00085      k_eccram_mode_detect_only = 3,
00086  } rx_eccram_mode_t;

```

8.77.5 Function Documentation

8.77.5.1 rx_eccram_clear_errors()

```

rx_err_t rx_eccram_clear_errors (
    void ) [nodiscard]

```

Clear 1-bit and 2-bit error status flags.

Writes k_rx_eccram1sts_clear and k_rx_eccram2sts_clear to acknowledge any outstanding error flags. Does not touch the captured addresses: those remain latched until the next error.

Returns

rx_err_t Error code

Return values

k_rx_ok	Flags cleared.
---------	----------------

Precondition

[rx_eccram_init\(\)](#) has been called.

ECCRAMPRCR protection does not guard ECCRAM1STS/ECCRAM2STS (verified in Manual section 60.2.13 – both registers are directly writable without PRCR unlock).

Postcondition

ECCRAM1STS.ECC1ERR == 0 and ECCRAM2STS.ECC2ERR == 0.

Note

Thread Safety: Call from ISR or task context; writes are atomic.

Since

Version 1.0.0

Definition at line 433 of file [rx_eccram.c](#).

```
00434 {
00435     volatile rx_eccram_regs_t* regs = eccram_regs();
00436     regs->eccram1sts = k_rx_eccram1sts_clear;
00437     regs->eccram2sts = k_rx_eccram2sts_clear;
00438     return k_rx_ok;
00439 }
```

References [rx_eccram_regs_t::eccram1sts](#), [rx_eccram_regs_t::eccram2sts](#), [eccram_regs\(\)](#), [k_rx_eccram1sts_clear](#), and [k_rx_eccram2sts_clear](#).

Here is the call graph for this function:

8.77.5.2 rx'eccram'get'error'status()

```
rx_err_t rx_eccram_get_error_status (
    rx_eccram_status_t * out) [nodiscard]
```

Read a snapshot of ECCRAM error status and captured addresses.

Reads ECCRAM1STS, ECCRAM2STS, ECCRAM1ECAD, and ECCRAM2ECAD into a plain struct. No registers are modified – call [rx_eccram_clear_errors\(\)](#) to acknowledge faults.

Parameters

out	out	Pointer to status struct populated on success.
-----	-----	--

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Status read successfully.
<code>k_rx_err_null_ptr</code>	out is nullptr.

Precondition

[rx_eccram_init\(\)](#) has been called.

out is a valid writable pointer.

Postcondition

out fields reflect the register state at call time.
No hardware state is modified by this call.

Note

Thread Safety: Safe for concurrent readers (pure register reads).

Since

Version 1.0.0

Definition at line 416 of file [rx_eccram.c](#).

```
00417 {
00418     RX_CHECK_NULL_PTR(out, s_tag, "out is nullptr");
00419
00420     volatile rx_eccram_regs_t* regs = eccram_regs();
00421

00423     const uint8_t s2 = regs->eccram2sts;
00424
00425     out->one_bit_error = (bool)((s1 & k_rx_eccram1sts_ecc1err_mask) != 0U);
00426     out->two_bit_error = (bool)((s2 & k_rx_eccram2sts_ecc2err_mask) != 0U);
00427     out->one_bit_addr = (uintptr_t)regs->eccram1ecad;
00428     out->two_bit_addr = (uintptr_t)regs->eccram2ecad;
00429
00430     return k_rx_ok;
00431 }
```

References [rx_eccram_regs_t::eccram1ecad](#), [rx_eccram_regs_t::eccram1sts](#), [rx_eccram_regs_t::eccram2ecad](#), [rx_eccram_regs_t::eccram2sts](#), [eccram_regs\(\)](#), [k_rx_eccram1sts_ecc1err_mask](#), [k_rx_eccram2sts_ecc2err_mask](#), [rx_eccram_status_t::one_bit_addr](#), [rx_eccram_status_t::one_bit_error](#), [s_tag](#), [rx_eccram_status_t::two_bit_addr](#), and [rx_eccram_status_t::two_bit_error](#).

Here is the call graph for this function:

8.77.5.3 rx_eccram_init()

```
rx_err_t rx_eccram_init (
    rx_eccram_mode_t mode) [nodiscard]
```

Initialise ECCRAM in the requested operating mode.

Performs the full initialisation sequence required by the RX72N HW manual:

1. Clear MSTPCRC.MSTPC6 under system PRCR unlock so that the ECCRAM control block is clocked (Manual section 60.4.1, page 2994).
2. Unlock ECCRAMPRCR and set ECCRAMMODE = k_rx_eccrammode_ecc_no_check so ECC bits are generated but nothing is checked.

3. Zero all 32 KB of ECCRAM using aligned 32-bit stores (Manual section 60.3.3: uninitialised ECC syndromes would falsely flag).
4. Switch ECCRAMMODE to the mode that backs the requested mode argument and re-lock ECCRAMPRCR.
5. For any mode other than `k_eccram_mode_disabled`, enable the 1-bit status-update latch (`ECCRAM1STSEN`).

Parameters

in	mode	Desired operating mode (see rx_eccram_mode_t)
----	------	--

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Initialisation successful.
<code>k_rx_err_invalid_arg</code>	mode is outside rx_eccram_mode_t range.
<code>k_rx_err_hw_init_failed</code>	Hardware mode read-back did not match.

Precondition

System clock is configured before this call.

Interrupts are globally disabled OR this function is called before any task can generate ECCRAM traffic.

Postcondition

`MSTPCRC.MSTPC6 == 0` (ECCRAM control block clocked).

All 32 KB of ECCRAM are zeroed with matching ECC syndromes.

`ECCRAMMODE` reflects mode.

Note

Thread Safety: Call once from `hardware_init()`. Not reentrant.

Warning

This function must run before any data is placed in the `.eccram` linker section – it wipes the region.

NASA Power of 10 Compliance:

- Rule 2: Zero-fill loop bounded by `k_rx_eccram_region_size_bytes / 4`.
- Rule 5: 2 preconditions, 3 postconditions.
- Rule 7: Every internal helper's return value is checked.

Here is the call graph for this function:

8.77.5.4 rx_eccram_region_end()

```
uintptr_t rx_eccram_region_end (
    void )
```

Return the inclusive end address of the ECCRAM data region.

Returns

Physical address 0x00FFFFFF as a uintptr_t.

Precondition

None.

Postcondition

Return value equals k_rx_eccram_region_end_addr.

Return value - rx_eccram_region_start() + 1 equals 32 KB.

Note

Thread Safety: Returns a compile-time constant; always safe.

8.77.5.5 rx'eccram'region'start()

```
uintptr_t rx_eccram_region_start (  
    void )
```

Return the inclusive start address of the ECCRAM data region.

Exposes the hardware-defined base of the ECC-protected region so that linker scripts and runtime allocators can place objects inside it without hardcoding the literal address.

Returns

Physical address 0x00FF8000 as a `uintptr_t`.

Precondition

None.

Postcondition

Return value equals `k_rx_eccram_region_base_addr`.

Return value is word-aligned.

Note

Thread Safety: Returns a compile-time constant; always safe.

8.77.5.6 rx_eccram_register_error_isr()

```
rx_err_t rx_eccram_register_error_isr (
    rx_eccram_on_1bit_fn_t on_1bit,
    rx_eccram_on_2bit_fn_t on_2bit,
    void * ctx) [nodiscard]
```

Register user callbacks for ECC error ISRs.

Installs 1-bit and/or 2-bit error callbacks that the driver's ISR trampoline will invoke on the respective RAM-error vectors. Passing nullptr for either callback leaves the previously installed handler in place, allowing callers to register them independently.

Dependency-Injection Rationale (NASA Rule 9 deviation)

Function pointers are permitted here because they are the exact pattern STAR uses to allow test mocks and application-level policy to substitute in without modifying the driver. See CLAUDE.md "SOLID Principles for C / Dependency Inversion".

Parameters

in	on_1bit	Handler invoked from ISR on 1-bit error (may be nullptr).
in	on_2bit	Handler invoked from ISR on 2-bit error (may be nullptr).
in	ctx	Opaque pointer passed through to the handlers.

Returns

rx_err_t Error code

Return values

k_rx_ok	Handlers installed.
k_rx_err_invalid_state	rx_eccram_init() has not yet been called.

Precondition

[rx_eccram_init\(\)](#) has been called.

Handlers, if non-null, are safe to call from interrupt context.

Postcondition

The driver's ISR trampolines dispatch to the supplied handlers.

ctx is retained until this function is called again.

Note

Thread Safety: Install once during init before interrupts are enabled, or guard calls at the task level.

```
00001 /**
00002  * @file rx_eccram.h
00003  * @brief ECC-Protected RAM (ECCRAM) Driver API
00004  *
00005  * @details
00006  * Public driver interface for the 32 KB ECC-protected RAM region on the
00007  * RX72N. Provides mode configuration, error-status readout, error
00008  * clearing, ISR registration for 1-bit/2-bit errors, and region
00009  * introspection (start/end addresses for use by linker scripts).
00010  *
00011  * @par STAR Use Case
00012  * Bit-flip-resistant storage for safety-critical mutable state:
00013  * - Motor PID integrator accumulators
00014  * - Last-good encoder counts
00015  * - nanopb frame sequence numbers
00016  * - IWDt kick counter
00017  * - shared_data_t handoff between motor_control_task and comm_task
00018  *
00019  * Single-bit errors are silently corrected by hardware; double-bit errors
00020  * trigger the registered on_2bit handler, which captures the failing
00021  * address and typically e-stops the system instead of acting on garbage.
00022  *
00023  * @par Initialization Order
00024  * 1. Call rx_eccram_init(k_eccram_mode_correct_and_detect) during
00025  *    hardware_init before any code places data in ECCRAM.
00026  * 2. The driver clears MSTPCRC.MSTPC6, enables ECC generation without
00027  *    error checking, zeroes the entire 32 KB region with 32-bit stores
00028  *    so every ECC syndrome matches its data, then switches to the
00029  *    requested check mode.
00030  * 3. Call rx_eccram_register_error_isr() to install application
00031  *    handlers (optional -- the driver installs safe defaults).
00032  *
00033  * @par Linker Integration
00034  * The driver provides `rx_eccram_region_start()` and
00035  * `rx_eccram_region_end()` so linker scripts can place a dedicated
00036  * `.eccram` output section between these addresses. See
00037  * `star-rx72n-firmware/linker.ld`.
00038  *

8.79 libs/rx_hal/inc/rx_gptw.h File Reference

GPTW PWM Driver for RX72N Motor Control.

```

#include <stdbool.h>
#include <stdint.h>
#include "rx_check.h"
#include "rx_err.h"

```

Include dependency graph for rx_gptw.h:

This graph shows which files directly or indirectly include this file:

Data Structures

- struct [rx_gptw_channel_id_t](#)
Type-safe GPTW channel wrapper (prevents accidental argument swaps).
- struct [rx_gptw_output_id_t](#)
Type-safe GPTW output wrapper (prevents accidental argument swaps).
- struct [rx_gptw_config_t](#)
GPTW PWM Configuration Structure.

Enumerations

- enum `rx_gptw_channel_t` : `uint8_t` { `k_gptw_channel_0` , `k_gptw_channel_1` , `k_gptw_channel_2` , `k_gptw_channel_3` }
GPTW Channel Identifiers for 4-Motor Control System.
- enum `rx_gptw_output_t` : `uint8_t` { `k_gptw_output_a` , `k_gptw_output_b` }
GPTW Output Channel Selection for Complementary PWM.
- enum `rx_gptw_wave_mode_t` : `uint8_t` { `k_gptw_wave_saw_pwm` , `k_gptw_wave_tri_pwm1` , `k_gptw_wave_tri_pwm2` , `k_gptw_wave_tri_pwm3` }
GPTW PWM Waveform Mode Selection.
- enum `rx_gptw_duty_calc_constants_t` : `uint8_t` { `k_gptw_duty_50_pct_num` = 50 , `k_gptw_duty_75_pct_num` = 75 , `k_gptw_duty_pct_denom` = 100 }
Named constants for duty cycle percentage calculations.
- enum `rx_gptw_count_t` : `uint8_t` { `k_rx_gptw_channel_count` = 4 }
Initialize all 4 GPTW channels with 90 degree phase staggering.

Functions

- static `rx_gptw_channel_id_t rx_gptw_channel_id` (`rx_gptw_channel_t` value)
Helper to construct a GPTW channel wrapper.
- static `rx_gptw_output_id_t rx_gptw_output_id` (`rx_gptw_output_t` value)
Helper to construct a GPTW output wrapper.
- `rx_err_t rx_gptw_init_all_staggered` (`const rx_gptw_config_t *configs`[`k_rx_gptw_channel_count`]
)
Initialize all 4 GPTW channels with 90-degree phase staggering.
- `rx_err_t rx_gptw_init_pwm` (`rx_gptw_channel_t` channel, `const rx_gptw_config_t *config`)
Initialize a single GPTW channel for PWM output.
- `rx_err_t rx_gptw_set_duty` (`rx_gptw_channel_id_t` channel, `rx_gptw_output_id_t` output, `float` duty_percent)
Set PWM duty cycle (floating-point percentage).
- `rx_err_t rx_gptw_set_duty_raw` (`rx_gptw_channel_t` channel, `rx_gptw_output_t` output, `uint32_t` duty_count)
Set PWM duty cycle using raw counter value.
- `rx_err_t rx_gptw_get_duty` (`rx_gptw_channel_t` channel, `rx_gptw_output_t` output, `float *duty_percent`)
Get current duty cycle as a floating-point percentage.
- `rx_err_t rx_gptw_get_period` (`rx_gptw_channel_t` channel, `uint32_t *period_count`)
Get the 32-bit PWM period count for a GPTW channel.
- `rx_err_t rx_gptw_enable_output` (`rx_gptw_channel_t` channel, `rx_gptw_output_t` output, `bool` enable)
Enable or disable a PWM output pin.
- `rx_err_t rx_gptw_start` (`rx_gptw_channel_t` channel)
Start the GPTW timer counter for PWM generation.
- `rx_err_t rx_gptw_stop` (`rx_gptw_channel_t` channel)
Stop the GPTW timer counter.
- `rx_err_t rx_gptw_deinit` (`rx_gptw_channel_t` channel)
Deinitialize a GPTW channel and release all resources.

8.79.1 Detailed Description

GPTW PWM Driver for RX72N Motor Control.

Production-grade PWM driver for the RX72N General PWM Timer (GPTW) peripheral, optimized for brushed DC motor control with H-bridge drivers. This module provides high-resolution 32-bit PWM generation with complementary outputs, deadtime insertion, and phase-staggered operation for 4-motor systems.

8.79.1.1 Purpose and Design Rationale

The GPTW peripheral is chosen over MTU for motor control because:

1. 32-bit resolution - Higher precision than MTU's 16-bit (0.000015% vs 0.0015%)
2. Dedicated motor pins - Port E pins optimized for PWM output
3. Hardware deadtime - Prevents H-bridge shoot-through without CPU overhead
4. Phase staggering - Reduces peak current draw and EMI

8.79.1.2 Key Features

PWM Generation:

- 4 independent channels (GPTW0-GPTW3) for 4 motors
- 32-bit counter resolution for precise duty cycle control
- Sawtooth (edge-aligned) or triangle (center-aligned) waveforms
- Complementary A/B outputs per channel for H-bridge control
- Configurable deadtime insertion (0-65535 ns)

Phase Staggering:

- 90-degree phase offset between channels
- Channel 0: 0deg, Channel 1: 90deg, Channel 2: 180deg, Channel 3: 270deg
- Spreads current draw across PWM period
- Reduces peak power supply current by ~75%
- Reduces conducted EMI by preventing simultaneous switching

Motor Control Integration:

- Direct interface with DRV8263H H-bridge drivers
- IN2/IN1 control mode support (sign-magnitude)
- Glitch-free duty cycle updates on period boundary
- Fast raw duty cycle API for tight control loops

8.79.1.3 Hardware Architecture

Pin Assignments (from hardware_pinout.h):

Motor	Channel	Output A	Output B	Function
Motor 0	GPTW0	PE5/GTIOC0A	PE2/GTIOC0B	Front-Left
Motor 1	GPTW1	PE4/GTIOC1A	PE1/GTIOC1B	Front-Right
Motor 2	GPTW2	PE3/GTIOC2A	PE0/GTIOC2B	Rear-Left
Motor 3	GPTW3	PE7/GTIOC3A	PE6/GTIOC3B	Rear-Right

Register Base Addresses:

Register Set	Base Address	Description
GPTW Common	0x000C2000	Shared control registers
GPTW0	0x000C2100	Channel 0 registers
GPTW1	0x000C2180	Channel 1 registers
GPTW2	0x000C2200	Channel 2 registers
GPTW3	0x000C2280	Channel 3 registers

Clock Configuration:

Parameter	Value	Notes
Clock Source	PCLKA	Peripheral Clock A
Clock Frequency	120 MHz	After system clock configuration
Counter Resolution	8.33 ns	1/120MHz
PWM Frequency	20 kHz	Typical for motor control
Period Counts	6000	120MHz / 20kHz
Duty Resolution	0.0167%	1/6000

8.79.1.4 PWM Waveform Modes

Triangle (Center-Aligned)

Counter: 0->Period->0->Period
 Update: At crest/trough
 Best for: Motor control

Sawtooth (Edge-Aligned)

Counter: 0->Period->0
 Update: At trough
 Best for: Simple PWM

8.79.1.5 Performance Characteristics

Operation	Execution Time	Memory Usage	Notes
rx_gptw_init_all_staggered()	~100 us	0 heap	One-time setup
rx_gptw_set_duty()	~5 us	0	Float calculation
rx_gptw_set_duty_raw()	~1 us	0	Direct register write
rx_gptw_get_duty()	~3 us	0	Register read + calc
rx_gptw_enable_output()	~1 us	0	Single register write

Memory Footprint:

- Static variables: ~64 bytes (initialization flags, period cache)
- Code size: ~2 KB (all functions)
- Stack usage: < 64 bytes (deepest call)
- Heap usage: 0 bytes (zero dynamic allocation)

8.79.1.6 Thread Safety and RTOS Integration

Thread-Safe Operations:

- [rx_gptw_set_duty\(\)](#) and [rx_gptw_set_duty_raw\(\)](#) are atomic register writes
- Safe to call from motor control ISR or ThreadX tasks
- No mutex required for duty cycle updates

Non-Thread-Safe Operations:

- [rx_gptw_init_all_staggered\(\)](#) - Call once during system initialization
- [rx_gptw_deinit\(\)](#) - Call only when no motor control active

Hardware Requirements:

Component	Requirement	Notes
MCU	Renesas RX72N	GPTW peripheral required
Clock	PCLKA @ 120 MHz	System clock configuration
Pins	Port E (PE0-PE7)	Configured via MPC
Power	3.3V I/O	LVC MOS compatible

Module Dependencies:

This module depends on:

- [rx_err.h](#) - Error code definitions
- [rx_check.h](#) - Parameter validation macros
- [rx72n_gptw_regs.h](#) - GPTW register definitions
- [rx72n_mpc_regs.h](#) - Pin mux configuration

This module is used by:

- [rx_motor.c](#) - Motor control driver
- [rx_drv8263.c](#) - H-bridge driver interface
- [motor_control_task.c](#) - Motor control task

NASA Power of 10 Compliance:

Rule	Status	Implementation
1. Simple control flow	↔ [OK]↔	No goto/setjmp/recursion
2. Fixed loop bounds	↔ [OK]↔	Loops bounded by <code>k_gptw_channel_3</code> (4 iterations max)
3. No dynamic allocation	↔ [OK]↔	Zero malloc/free, all static
4. Small functions	↔ [OK]↔	All functions < 60 lines
5. Assertions (≥ 2 per function)	↔ [OK]↔	Minimum 2 validation checks per function
6. Narrow scope	↔ [OK]↔	File-scope statics, minimal globals
7. Check return values	↔ [OK]↔	All functions return <code>rx_err_t</code>
8. Limited preprocessor	↔ [OK]↔	C23 typed enums, minimal macros
9. Pointer restrictions	↔ [OK]↔	Single-level pointers only
10. Compiler warnings	↔ [OK]↔	Compiles with <code>-Wall -Wextra -Werror</code>

SOLID Principles:

Single Responsibility (S):

- This module handles ONLY GPTW PWM generation
- Motor control logic is in `rx_motor.c`
- H-bridge configuration is in `rx_drv8263.c`

Open/Closed (O):

- Extensible via `rx_gptw_config_t` structure

- New waveform modes can be added without modifying existing code
- Frequency and deadtime configurable at runtime

Liskov Substitution (L):

- All functions return `rx_err_t` with consistent semantics
- Channel and output parameters are validated uniformly

Interface Segregation (I):

- Separate functions for float vs raw duty cycle
- Init, set, get, enable are independent operations
- Wrapper types prevent parameter swapping

Dependency Inversion (D):

- Depends on abstract error codes, not specific implementations
- Motor control depends on this interface, not hardware registers directly

8.79.2 Data Structure Documentation

8.79.2.1 struct rx'gptw'channel'id't

Type-safe GPTW channel wrapper (prevents accidental argument swaps).

Wraps [rx_gptw_channel_t](#) in a struct to leverage the C type system for catching argument transposition errors at compile time. Without this wrapper, swapping channel and output arguments (both `uint8_t`) would compile silently. Construct via [rx_gptw_channel_id\(\)](#) helper function.

Invariant

value must be a valid [rx_gptw_channel_t](#) value (`k_gptw_channel_0` through `k_gptw_channel_3`)

```
rx_gptw_channel_id_t ch = rx_gptw_channel_id(k_gptw_channel_0);
```

Collaboration diagram for `rx_gptw_output_id_t`:

Data Fields

rx_gptw_output_t	value	GPTW output identifier (A or B)
----------------------------------	-------	---------------------------------

8.79.2.3 struct rx_gptw_config_t

GPTW PWM Configuration Structure.

Contains all configuration parameters for initializing a GPTW channel for PWM output. This structure is passed to [rx_gptw_init_pwm\(\)](#) or [rx_gptw_init_all_staggered\(\)](#) to configure the timer.

8.79.2.4 Configuration Guidelines

Frequency Selection:

- Motor control: 15-25 kHz (above audible range, efficient switching)
- LED dimming: 100-1000 Hz (no flicker, simple filtering)
- Servo control: 50-400 Hz (standard RC servo range)

Deadtime Selection:

- Minimum: 100 ns (propagation delay margin)
- Typical: 500-1000 ns (good balance)
- Maximum: 5000 ns (very conservative, reduces efficiency)

Configuration Parameter Table:

Parameter	Min	Max	Default	Unit	Notes
frequency_hz	100	1000000	20000	Hz	Limited by PCLKA/2
deadtime_ns	0	65535	1000	ns	0 disables deadtime
wave_mode	0	3	0	enum	See rx_gptw_wave_mode_t
enable_complementary	false	true	true	bool	For H-bridge
invert_polarity	false	true	false	bool	Active-low output

Memory Layout:

Offset	Size	Field	Type	Alignment
0	4	frequency_hz	uint32_t	4
4	2	deadtime_ns	uint16_t	2
6	1	wave_mode	uint8_t	1
7	1	enable_complementary	bool	1
8	1	invert_polarity	bool	1
9-11	3	(padding)	-	-
Total	12	-	-	4

Usage Example (Motor Control):

```
// Standard motor control configuration
rx_gptw_config_t motor_config = {
    .frequency_hz = 20000,      // 20 kHz (inaudible)
    .deadtime_ns = 1000,       // 1 us deadtime
    .wave_mode = k_gptw_wave_saw_pwm, // Edge-aligned
    .enable_complementary = true, // H-bridge requires this
    .invert_polarity = false    // Active-high outputs
};

rx_err_t err = rx_gptw_init_all_staggered(&motor_config);
if (err != k_rx_ok) {
    rx_log_error("GPTW", "Failed to initialize: %d", err);
}
```

Usage Example (LED Dimming):

```
// LED PWM configuration (no complementary needed)
rx_gptw_config_t led_config = {
    .frequency_hz = 1000,      // 1 kHz (no flicker)
    .deadtime_ns = 0,         // No deadtime for LEDs
    .wave_mode = k_gptw_wave_saw_pwm,
    .enable_complementary = false, // Single output only
    .invert_polarity = false
};

rx_err_t err = rx_gptw_init_pwm(k_gptw_channel_0, &led_config);
```

Invariant

frequency_hz > 0 (enforced by rx_gptw_init_*)
 frequency_hz <= PCLKA / 2 (Nyquist limit)
 wave_mode in [0, 3] (valid enum range)

Note

Structure is copied during initialization; no need to keep alive

Warning

Invalid configurations rejected with k_rx_err_invalid_arg

Since

Version 1.0.0

Definition at line 697 of file [rx_gptw.h](#).

Collaboration diagram for rx_gptw_config_t:

Data Fields

uint8_t	bit_a	
uint8_t	bit_b	
uint16_t	deadtime_ns	Deadtime in nanoseconds. Deadtime inserted between complementary output transitions to prevent shoot-through (simultaneous conduction of high-side and low-side switches). Set to 0 to disable deadtime insertion. Deadtime Calculation: $\text{Deadtime Counts} = \frac{\text{deadtime_ns} \times f_{PCLKA}}{10^9}$ At 120 MHz: 1000 ns = 120 counts Valid Range: [0, 65535 ns] Recommended: 1000 ns (1 us) for DRV8263H Warning Too short may cause shoot-through; too long reduces efficiency

bool	enable_complementary	Enable complementary outputs. When true, Output B is the inverted version of Output A with deadtime inserted. Required for H-bridge motor control. • true: Both A and B outputs active (complementary) • false: Only Output A active, Output B held low Warning When complementary mode is enabled, GTCCRB is tied to GTCCRA by the hardware. Writing GTCCRB directly has no effect; the output B duty is always the complement of output A. For independent A/B control (e.g., DRV8263H IN2/IN1 mode), set this to false.
uint32_t	frequency_hz	PWM frequency in Hz. Sets the PWM switching frequency. For motor control, 15-25 kHz is typical (above audible range). Higher frequencies reduce current ripple but increase switching losses. Frequency Calculation: $\text{Period Count} = \frac{f_{PCLKA}}{f_{PWM}} - 1$ Where $f_{PCLKA} = 120 \text{ MHz}$ Valid Range: [100, 1000000 Hz] Recommended: 20000 Hz for motor control Note Actual frequency may differ slightly due to integer division

bool	invert_polarity	Invert PWM polarity. When true, inverts the PWM output polarity. • false: HIGH during duty cycle, LOW otherwise (active-high) • true: LOW during duty cycle, HIGH otherwise (active-low) Note Use for active-low driver inputs or inverted LED connections
uint8_t	port_a_idx	Pin coordinates for GTIOC*A and GTIOC*B outputs. The lib does not know the board's pin map. Caller MUST set these to the actual pads where GTIOC_A and GTIOC_B should appear. Source the values from a board-level pin map header (e.g. src/inc/hardware_config.h). port*_idx is the standard RX72N port index: 1, 2, 8, etc., with PORTA=10, PORTB=11, PORTC=12, PORTD=13, PORTE=14, PORTF=15. bit_* is the bit position within that port (0..7).
uint8_t	port_b_idx	
rx_gptw_wave_mode_t	wave_mode	Waveform mode (sawtooth or triangle). Selects counter behavior and PWM alignment. • Sawtooth: Edge-aligned, simpler, single update point • Triangle: Center-aligned, symmetric ripple, better for motors See also rx_gptw_wave_mode_t for detailed mode descriptions

8.79.3 Enumeration Type Documentation

8.79.3.1 rx`gptw`channel` t

enum [rx_gptw_channel_t](#) : uint8_t

GPTW Channel Identifiers for 4-Motor Control System.

Identifies the four GPTW timer channels used for motor PWM generation. Each channel controls one motor through complementary A/B outputs connected to a DRV8263H H-bridge driver.

8.79.3.2 Channel Architecture

Each GPTW channel provides:

- 32-bit up/down counter
- Two compare/capture registers (GTCCRA, GTCCRB)
- Two output pins (GTIOCnA, GTIOCnB)
- Independent deadtime insertion
- Synchronized start/stop capability

Channel-to-Motor Mapping:

Channel	Motor	Position	Register Base	Phase Offset
GPTW0	Motor 0	Front-Left	0x000C2100	0deg
GPTW1	Motor 1	Front-Right	0x000C2180	90deg
GPTW2	Motor 2	Rear-Left	0x000C2200	180deg
GPTW3	Motor 3	Rear-Right	0x000C2280	270deg

Pin Assignments:

Channel	Output A	Output B	MPC Setting
k_gptw_channel_0	PE5/GTIOC0A	PE2/GTIOC0B	PSEL = 0x1E
k_gptw_channel_1	PE4/GTIOC1A	PE1/GTIOC1B	PSEL = 0x1E
k_gptw_channel_2	PE3/GTIOC2A	PE0/GTIOC2B	PSEL = 0x1E
k_gptw_channel_3	PE7/GTIOC3A	PE6/GTIOC3B	PSEL = 0x1E

Usage Example:

```
// Initialize all channels with staggered phases
rx_gptw_config_t config = {
    .frequency_hz = 20000,
    .deadtime_ns = 1000,
    .wave_mode = k_gptw_wave_saw_pwm,
    .enable_complementary = true,
    .invert_polarity = false
};
rx_gptw_init_all_staggered(&config);

// Set duty cycle for motor 0 (front-left)
rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
    rx_gptw_output_id(k_gptw_output_a),
    50.0F); // 50% duty cycle
```

Invariant

Channel values are contiguous: 0, 1, 2, 3

All channels use same register structure (0x80 byte spacing)

Channel count equals motor count (4)

Note

C23 typed enum with uint8_t underlying type (1-byte values)

Channel 4 and 5 exist in hardware but are not used in STAR

Version 1.0.0

Enumerator

<code>k_gptw_channel_0</code>	GPTW0 channel for Motor 0 (Front-Left). Register base: 0x000C2100. Outputs: PE5/GTIOC0A, PE2/GTIOC0B. Phase offset: 0deg in staggered mode
<code>k_gptw_channel_1</code>	GPTW1 channel for Motor 1 (Front-Right). Register base: 0x000C2180. Outputs: PE4/GTIOC1A, PE1/GTIOC1B. Phase offset: 90deg in staggered mode
<code>k_gptw_channel_2</code>	GPTW2 channel for Motor 2 (Rear-Left). Register base: 0x000C2200. Outputs: PE3/GTIOC2A, PE0/GTIOC2B. Phase offset: 180deg in staggered mode
<code>k_gptw_channel_3</code>	GPTW3 channel for Motor 3 (Rear-Right). Register base: 0x000C2280. Outputs: PE7/GTIOC3A, PE6/GTIOC3B. Phase offset: 270deg in staggered mode

Definition at line 278 of file [rx_gptw.h](#).

```

00278     : uint8_t {
00279     k_gptw_channel_0 =
00280     0, /**< GPTW0 channel for Motor 0 (Front-Left). Register base: 0x000C2100. Outputs: PE5/GTIOC0A,
00281     PE2/GTIOC0B. Phase offset: 0deg in staggered mode */
00281     k_gptw_channel_1 =
00282     1, /**< GPTW1 channel for Motor 1 (Front-Right). Register base: 0x000C2180. Outputs: PE4/GTIOC1A,
00283     PE1/GTIOC1B. Phase offset: 90deg in staggered mode */
00283     k_gptw_channel_2 =
00284     2, /**< GPTW2 channel for Motor 2 (Rear-Left). Register base: 0x000C2200. Outputs: PE3/GTIOC2A,
00285     PE0/GTIOC2B. Phase offset: 180deg in staggered mode */
00285     k_gptw_channel_3 =
00286     3, /**< GPTW3 channel for Motor 3 (Rear-Right). Register base: 0x000C2280. Outputs: PE7/GTIOC3A,
00287     PE6/GTIOC3B. Phase offset: 270deg in staggered mode */
00287 } rx_gptw_channel_t;
```

8.79.3.3 rx_gptw_count_t

```
enum rx_gptw_count_t : uint8_t
```

Initialize all 4 GPTW channels with 90 degree phase staggering.

Configures GPTW0-3 for synchronized PWM operation with phase offsets that spread current draw across the PWM period. This is the recommended initialization function for 4-motor systems as it reduces peak current and EMI compared to synchronized PWM.

8.79.3.4 Phase Staggering Architecture

Phase staggering offsets the start of each channel's PWM period:

- Channel 0: 0deg (reference phase)
- Channel 1: 90deg (period / 4 offset)
- Channel 2: 180deg (period / 2 offset)
- Channel 3: 270deg (3 x period / 4 offset)

Phase Staggered PWM (4 channels at 50% duty)

8.79.3.5 Benefits of Phase Staggering

1. **Reduced Peak Current:** Instead of all motors switching simultaneously, current draw is spread across the period, reducing peak by up to 75%
2. **Lower EMI:** Staggered edges reduce conducted emissions
3. **Smaller Capacitors:** Lower peak current allows smaller power supply capacitors
4. **Better Power Quality:** More constant current draw improves voltage regulation

8.79.3.6 Algorithm Steps

1. Validate configuration parameters (NULL check, frequency range, wave mode)
2. Calculate period count from frequency and PCLKA
3. Enable GPTW module clock (MSTPCRA.MSTPA7 = 0)
4. Configure MPC for Port E pins (GTIOC function select)
5. For each channel (0-3):
 - a. Configure timer mode register (GTCR)
 - b. Set period register (GTPR)
 - c. Calculate and set phase offset (GTCNT initial value)
 - d. Configure output mode and polarity (GTIOR)
 - e. Set deadtime registers (GTDVU, GTDVD)
 - f. Set initial duty cycle to 0% (GTCCRA, GTCCRB)
6. Start all channels simultaneously (GTSTR)

Parameters

in	config	Common configuration for all channels
		• config->frequency_hz: PWM frequency [100, 1000000] Hz • config->deadtime_ns: Deadtime [0, 65535] ns • config->wave_mode: Waveform mode (sawtooth or triangle) • config->enable_complementary: Enable A/B complementary outputs • config->invert_polarity: Invert output polarity

Returns

rx_err_t Error code indicating success or failure reason

Return values

k_rx_ok	All 4 channels initialized successfully
k_rx_err_null_ptr	config pointer is nullptr
k_rx_err_invalid_arg	frequency_hz is 0 or wave_mode out of range
k_rx_err_hw_error	GPTW hardware access failed (NULL register pointer)

Precondition

System clock configured (PCLKA = 120 MHz)
 Port E pins not used by other peripherals

Postcondition

All 4 GPTW channels running with 90deg phase offsets
 All duty cycles initialized to 0% (motors stopped)
 MPC configured for GTIOC function on Port E pins

Invariant

Phase relationship maintained: $\text{Ch1} = \text{Ch0} + 90\text{deg}$, $\text{Ch2} = \text{Ch0} + 180\text{deg}$, $\text{Ch3} = \text{Ch0} + 270\text{deg}$

Note

Thread-safe: Call only once during system initialization

Propagates errors from [internal_calculate_period\(\)](#), [internal_configure_gptw_hardware\(\)](#)

Warning

Calling this function while motors are running will cause glitches

Attention

This function should be used INSTEAD of [rx_gptw_init_pwm\(\)](#) for motor control

Performance:

- Execution time: ~ 100 us at 240 MHz
- Memory usage: 0 heap, ~ 64 bytes stack

Example (Complete Motor System Initialization):

```
#include "rx_gptw.h"
#include "rx_drv8263.h"
#include "rx_motor.h"

rx_err_t motor_system_init(void)
{
    // Configure GPTW for 20 kHz PWM with 1 us deadtime
    rx_gptw_config_t pwm_config = {
        .frequency_hz = 20000,
        .deadtime_ns = 1000,
        .wave_mode = k_gptw_wave_saw_pwm,
        .enable_complementary = true,
        .invert_polarity = false
    };

    rx_err_t err = rx_gptw_init_all_staggered(&pwm_config);
    if (err != k_rx_ok) {
        rx_log_error("MOTOR", "GPTW init failed: %d", err);
        return err;
    }

    // Initialize H-bridge drivers
    err = rx_drv8263_init_all();
    if (err != k_rx_ok) {
        rx_log_error("MOTOR", "DRV8263H init failed: %d", err);
        return err;
    }

    rx_log_info("MOTOR", "Motor system initialized (4 channels, 20kHz, staggered)");
    return k_rx_ok;
}
```

Example (Verify Phase Offsets):

```
// Diagnostic: read counter values to verify phase relationship
void verify_phase_stagger(void)
{
    uint32_t cnt0, cnt1, cnt2, cnt3;
    uint32_t period;

    rx_gptw_get_period(k_gptw_channel_0, &period);

    // Read all counters (will have some jitter due to sequential reads)
    cnt0 = GPTW0->GTCNT;
    cnt1 = GPTW1->GTCNT;
    cnt2 = GPTW2->GTCNT;
    cnt3 = GPTW3->GTCNT;

    // Expected: cnt1 ~ cnt0 + period/4, cnt2 ~ cnt0 + period/2, etc.
    rx_log_debug("GPTW", "Period=%lu, Offsets: %lu, %lu, %lu, %lu",
        period, cnt0, cnt1 - cnt0, cnt2 - cnt0, cnt3 - cnt0);
}
```

Version 1.0.0

NASA Power of 10 Compliance:

- Rule 1: [OK] No goto/setjmp/recursion
- Rule 2: [OK] Loop bounded by k_gptw_channel_3 (4 iterations)
- Rule 5: [OK] 2 preconditions, 3 postconditions
- Rule 7: [OK] All internal function returns checked

Enumerator

k_rx_gptw_channel_count	
-------------------------	--

Definition at line 964 of file [rx_gptw.h](#).

```
00964         : uint8_t {
00965     k_rx_gptw_channel_count = 4,
00966 } rx_gptw_count_t;
```

8.79.3.7 rx_gptw_duty_calc_constants_t

```
enum rx_gptw_duty_calc_constants_t : uint8_t
```

Named constants for duty cycle percentage calculations.

Provides named numerators and a common denominator for computing raw duty counts as integer fractions of the period. Using named constants instead of magic literals satisfies NASA Power of 10 Rule 8 (no magic numbers).

Example:

```
// 50% duty: period * 50 / 100
uint32_t half = (period * k_gptw_duty_50_pct_num) / k_gptw_duty_pct_denom;
```

Invariant

All numerator constants must be $\leq$ k_gptw_duty_pct_denom (non-negative)

k_gptw_duty_pct_denom must be non-zero (denominator for percentage calculation)

See also

[rx_gptw_set_duty_raw\(\)](#) Uses these constants in documentation examples

[rx_gptw_get_period\(\)](#) Provides the period value for the calculation

Since

Version 1.0.0

Enumerator

k_gptw_duty_50_pct_num	Numerator for 50% duty cycle calculation
k_gptw_duty_75_pct_num	Numerator for 75% duty cycle calculation
k_gptw_duty_pct_denom	Denominator for percentage duty calculations

Definition at line 486 of file [rx_gptw.h](#).

```
00486      : uint8_t {
00487   k_gptw_duty_50_pct_num = 50, /**< Numerator for 50% duty cycle calculation */
00488   k_gptw_duty_75_pct_num = 75, /**< Numerator for 75% duty cycle calculation */
00489   k_gptw_duty_pct_denom = 100, /**< Denominator for percentage duty calculations */
00490 } rx_gptw_duty_calc_constants_t;
```

8.79.3.8 rx_gptw_output_t

```
enum rx\_gptw\_output\_t : uint8_t
```

GPTW Output Channel Selection for Complementary PWM.

Selects between the two outputs (A and B) available on each GPTW channel. Each output has an independent duty cycle and is controlled separately.

8.79.3.9 Independent Output Mode (STAR Configuration)

For the DRV8263H motor driver in IN2/IN1 mode, the GPTW outputs operate independently (not in complementary mode). Each output has its own compare register and duty cycle:

- Output A: Static direction signal (0% or 100% duty)
- Output B: Variable-duty PWM for speed control

The outputs are NOT inverted versions of each other and no hardware deadtime insertion is used. This is safe because the DRV8263H has integrated shoot-through protection on its internal H-bridge FETs.

8.79.3.10 IN2/IN1 Mode (Sign-Magnitude)

For DRV8263H H-bridge control in IN2/IN1 mode:

- Output A: Connected to IN2 (direction) input - controls direction
- Output B: Connected to IN1 (PWM) input - controls PWM duty

H-Bridge Connection:

Output	DRV8263H Pin	Function	Signal Type
Output A (GTIOCnA)	IN2	Direction control	Static HIGH/LOW
Output B (GTIOCnB)	IN1	PWM speed control	PWM waveform

Usage Example:

```
// Set forward direction at 75% duty for motor 0
// Output A = HIGH (forward direction)
rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
    rx_gptw_output_id(k_gptw_output_a),
    100.0F); // IN2 = HIGH (direction)

// Output B = PWM at 75% (motor speed)
rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
    rx_gptw_output_id(k_gptw_output_b),
    75.0F); // IN1 = 75% PWM

// Reverse direction: set Output A LOW
rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
    rx_gptw_output_id(k_gptw_output_a),
    0.0F); // IN2 = LOW (reverse)
```

Invariant

Output values are 0 (A) or 1 (B) only
Both outputs available on all channels

Note

C23 typed enum with uint8_t underlying type

Warning

In independent mode, each output is controlled separately; the DRV8263H handles shoot-through protection internally

Since

Version 1.0.0

Enumerator

k_gptw_output_a	GTIOCA output pin. Connected to DRV8263H IN2 (direction) in IN2/IN1 mode. Controls motor direction: HIGH=forward, LOW=reverse
k_gptw_output_b	GTIOCB output pin. Connected to DRV8263H IN1 (PWM) in IN2/IN1 mode. PWM duty cycle controls motor speed (0-100%)

Definition at line 354 of file [rx_gptw.h](#).

```

00354     : uint8_t {
00355     k_gptw_output_a =
00356     0, /**< GTIOCA output pin. Connected to DRV8263H IN2 (direction) in IN2/IN1 mode. Controls motor direction:
        HIGH=forward, LOW=reverse */
00357     k_gptw_output_b =
00358     1, /**< GTIOCB output pin. Connected to DRV8263H IN1 (PWM) in IN2/IN1 mode. PWM duty cycle controls motor
        speed (0-100%) */
00359 } rx_gptw_output_t;

```

8.79.3.11 rx_gptw_wave_mode_t

```
enum rx\_gptw\_wave\_mode\_t : uint8_t
```

GPTW PWM Waveform Mode Selection.

Selects the PWM waveform generation mode. The mode determines counter behavior, output alignment, and duty cycle update timing. Motor control typically uses sawtooth (edge-aligned) or triangle (center-aligned) modes.

8.79.3.12 Waveform Comparison

Sawtooth (Edge-Aligned):

- Counter counts up from 0 to period, then resets to 0
- PWM edges aligned to period start
- Simpler timing, lower switching losses
- Asymmetric current ripple

Triangle (Center-Aligned):

- Counter counts up to period, then down to 0
- PWM pulses centered in period
- Symmetric current ripple (better for motors)
- Reduced EMI due to staggered edges

Sawtooth Mode
Counter: 0..P repeats
Update: trough only
PWM edges: aligned to start
Best for: LED dimming

Triangle Mode
Counter: 0..P..0 repeats
Update: crest and/or trough
PWM edges: centered
Best for: motor control

Mode Selection Guide:

Mode	Counter Pattern	Update Timing	Use Case
k_gptw_wave_saw_pwm	0->P->0 (reset)	Trough	Simple PWM, LEDs
k_gptw_wave_tri_pwm1	0->P->0 (fold)	Trough	Motor control (standard)
k_gptw_wave_tri_pwm2	0->P->0 (fold)	Crest+↔ Trough	Motor control (fast update)
k_gptw_wave_tri_pwm3	0->P->0 (fold)	64-bit at trough	High-precision motor

Mathematical Model:

Sawtooth PWM Frequency:

$$f_{PWM} = \frac{f_{PCLKA}}{(GTPR + 1)}$$

Triangle PWM Frequency (half the sawtooth frequency for same period):

$$f_{PWM} = \frac{f_{PCLKA}}{2 \times (GTPR + 1)}$$

Where:

- $f_{PCLKA} = 120$ MHz (peripheral clock)
- $GTPR$ = Period register value

Usage Example:

```
// Configure for motor control with triangle wave (center-aligned)
rx_gptw_config_t config = {
    .frequency_hz = 20000,    // 20 kHz PWM
    .deadtime_ns = 1000,     // 1 us deadtime
    .wave_mode = k_gptw_wave_tri_pwm1, // Triangle, trough update
    .enable_complementary = true,
    .invert_polarity = false
};

// For simple LED dimming, use sawtooth
rx_gptw_config_t led_config = {
    .frequency_hz = 1000,    // 1 kHz (no audible noise)
    .wave_mode = k_gptw_wave_saw_pwm, // Sawtooth (simpler)
    .enable_complementary = false,
    .invert_polarity = false
};
```

Invariant

Mode values map directly to GTCR.MD bit field (0-3)
 All modes support complementary output with deadtime

Note

C23 typed enum with uint8_t underlying type
 Triangle modes have half the effective PWM frequency for same period

See also

Since

Version 1.0.0

Enumerator

k_gptw_wave_saw_pwm	Sawtooth-wave PWM (edge-aligned). Counter: 0->Period->reset. Single update point at trough. Best for simple PWM applications. GTCR.MD = 0b000
k_gptw_wave_tri_pwm1	Triangle-wave PWM mode 1 (center-aligned). Counter: 0->Period->0. Update at trough only. Best for motor control with standard update rate. GTCR.MD = 0b100
k_gptw_wave_tri_pwm2	Triangle-wave PWM mode 2 (center-aligned). Counter: 0->Period->0. Update at both crest and trough. Best for motor control requiring fast duty updates. GTCR.MD = 0b101

<code>k_gptw_wave_tri_pwm3</code>	Triangle-wave PWM mode 3 (center-aligned). Counter: 0->Period->0. 64-bit buffer transfer at trough. Best for high-precision motor control. GTCR.MD = 0b110
-----------------------------------	--

Definition at line 452 of file [rx_gptw.h](#).

```

00452         : uint8_t {
00453     k_gptw_wave_saw_pwm =
00454     0, /**< Sawtooth-wave PWM (edge-aligned). Counter: 0->Period->reset. Single update point at trough. Best for simple
        PWM applications. GTCR.MD = 0b000 */
00455     k_gptw_wave_tri_pwm1 =
00456     1, /**< Triangle-wave PWM mode 1 (center-aligned). Counter: 0->Period->0. Update at trough only. Best for motor
        control with standard update rate. GTCR.MD = 0b100 */
00457     k_gptw_wave_tri_pwm2 =
00458     2, /**< Triangle-wave PWM mode 2 (center-aligned). Counter: 0->Period->0. Update at both crest and trough. Best
        for motor control requiring fast duty updates. GTCR.MD = 0b101 */
00459     k_gptw_wave_tri_pwm3 =
00460     3, /**< Triangle-wave PWM mode 3 (center-aligned). Counter: 0->Period->0. 64-bit buffer transfer at trough. Best for
        high-precision motor control. GTCR.MD = 0b110 */
00461 } rx_gptw_wave_mode_t;

```

8.79.4 Function Documentation

8.79.4.1 rx_gptw_channel_id()

```

rx\_gptw\_channel\_id\_t rx_gptw_channel_id (
    rx\_gptw\_channel\_t value)    [inline], [static]

```

Helper to construct a GPTW channel wrapper.

Provides type-safe wrapper construction with NASA Power of 10 Rule 5 validation (minimum 2 checks per function):

- Pre-condition: Input value is within valid channel range [0-3]
- Post-condition: Wrapper correctly stores the input value

Parameters

in	value	GPTW channel enum value (<code>k_gptw_channel_0</code> to <code>k_gptw_channel_3</code>)
----	-------	--

Returns

Wrapped channel ID for type-safe function calls

Precondition

value must be a valid [rx_gptw_channel_t](#) in range [`k_gptw_channel_0`, `k_gptw_channel_3`]
 Caller must pass a compile-time known or previously validated channel value

Postcondition

Returned wrapper .value field equals the input value
 Wrapper is immediately usable in any API accepting [rx_gptw_channel_id_t](#)

Note

Reentrant and lock-free; contains no shared mutable state

See also

[rx_gptw_output_id\(\)](#) Companion wrapper constructor for output parameter

[rx_gptw_channel_id_t](#) Wrapper type constructed by this function

Since

Version 1.0.0

Definition at line 564 of file [rx_gptw.h](#).

```
00565 {
00566     /* Pre-condition: channel must be in valid range */
00567     /* Note: value >= k_gptw_channel_0 is always true for uint8_t since k_gptw_channel_0 == 0 */
00568     RX_ASSERT(value <= k_gptw_channel_3, "GPTW channel out of range");
00569
00570     const rx_gptw_channel_id_t id = {.value = value};
00571
00572     return id;
00573 }
```

References [k_gptw_channel_3](#).

8.79.4.2 rx_gptw_deinit()

```
rx_err_t rx_gptw_deinit (
    const rx_gptw_channel_t channel)    [nodiscard]
```

Deinitialize a GPTW channel and release all resources.

Performs a full shutdown sequence: stops the timer counter, disables both PWM outputs, resets the compare and period registers, and marks the channel as uninitialized. After deinit, the channel must be re-initialized via [rx_gptw_init_pwm\(\)](#) before use.

Parameters

in	channel	GPTW channel number (valid: 0-3)
----	---------	----------------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, channel fully deinitialized
k_rx_err_invalid_arg	Channel out of range

Precondition

Channel should be initialized (safe to call if already deinitialized)
Motor outputs should be in a safe state before deinit

Postcondition

Timer stopped, outputs disabled, channel marked uninitialized
All channel registers reset to default values

Note

Not thread-safe. Caller must provide synchronization.

Example:

```
// Full shutdown of GPTW channel 0
rx_err_t err = rx_gptw_deinit(k_gptw_channel_0);
if (err == k_rx_ok) {
    // Channel released, must call rx_gptw_init_pwm() before reuse
}
```

See also

[rx_gptw_init_pwm\(\)](#) Re-initialize after deinit
[rx_gptw_stop\(\)](#) Stop timer without full deinit

Since

Version 1.0.0

Deinitialize a GPTW channel and release all resources.

Stops the timer, disables both PWM outputs (A and B), and resets the counter to zero. Call only when motor control is no longer active.

Precondition

Motor using this channel must be stopped before calling
channel must be in range [k_gptw_channel_0, k_gptw_channel_3]

Postcondition

Timer counter stopped (GTCR.CST = 0)
Both outputs disabled (GTIOR.OAE = 0, GTIOR.OBE = 0)
Counter register zeroed (GTCNT = k_gptw_period_zero)

Invariant

Write protection re-locked (GTWP) on all exit paths

Note

Not thread-safe: modifies hardware registers directly

Does not clear `s_gptw_initialized[]` or `s_gptw_period[]`

Warning

Ensure motor is at rest before calling to prevent abrupt stop

```
rx_err_t err = rx_gptw_deinit(k_gptw_channel_0);
```

See also

[rx_gptw_init_all_staggered\(\)](#) Re-initialize after deinit

Here is the call graph for this function:

8.79.4.3 rx`gptw`enable`output()

```
rx_err_t rx_gptw_enable_output (
    const rx_gptw_channel_t channel,
    const rx_gptw_output_t output,
    bool enable) [nodiscard]
```

Enable or disable a PWM output pin.

Controls the GTONCR (General Timer Output Negation Control Register) bits that gate the PWM signal to the physical pin. When disabled, the pin is driven to its inactive level (determined by polarity configuration).

Parameters

in	channel	GPTW channel number (valid: 0-3)
in	output	Output channel (k_gptw_output_a or k_gptw_output_b)
in	enable	true to drive PWM on pin, false to hold pin inactive

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, output enable state updated
k_rx_err_invalid_arg	Channel or output out of range
k_rx_err_invalid_state	Channel not initialized

Precondition

Channel must be initialized via rx_gptw_init_pwm()

Output must be k_gptw_output_a or k_gptw_output_b

Postcondition

GTONCR bit updated for the specified output

Pin either drives PWM signal or holds inactive level

Note

Not thread-safe. Caller must provide synchronization.

Example:

```
// Enable PWM output on channel 0, output A
rx_err_t err = rx_gptw_enable_output(k_gptw_channel_0, k_gptw_output_a, true);
if (err != k_rx_ok) {
    // Handle output enable failure
}
```

See also

[rx_gptw_start\(\)](#) Start timer (separate from output enable)

[rx_gptw_stop\(\)](#) Stop timer (separate from output enable)

Since

Version 1.0.0

Enable or disable a PWM output pin.

Implementation of [rx_gptw_enable_output\(\)](#) - see [rx_gptw.h](#) for complete documentation.

Controls the Output Enable bits (OAE/OBE) in the GTIOR register. When disabled, the corresponding output pin is held in its initial state (typically LOW).

8.79.4.4 Register Modification

Output	Bit Modified	Effect
Output A	GTIOR.OAE	Enable/disable GTIOCnA pin
Output B	GTIOR.OBE	Enable/disable GTIOCnB pin

Precondition

Channel initialized via [rx_gptw_init_*](#)()

Postcondition

GTIOR.OAE or GTIOR.OBE modified

Write protection re-enabled

Note

Not thread-safe: Modifies hardware registers

Timer continues running even when output disabled

Warning

Disable outputs before motor emergency stop to ensure safe state

Here is the call graph for this function:

8.79.4.5 rx_gptw_get_duty()

```

rx_err_t rx_gptw_get_duty (
    const rx_gptw_channel_t channel,

```

```
const rx_gptw_output_t output,
float * duty_percent) [nodiscard]
```

Get current duty cycle as a floating-point percentage.

Reads the current compare register value for the specified output and converts it to a percentage of the period count. The value reflects the most recently committed duty cycle (may differ from the buffered value pending a period boundary update).

Parameters

in	channel	GPTW channel number (valid: 0-3)
in	output	Output channel (k_gptw_output_a or k_gptw_output_b)
out	duty_percent	Pointer to store duty cycle in percent [0.0, 100.0]

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, duty_percent written
k_rx_err_null_ptr	duty_percent is nullptr
k_rx_err_invalid_arg	Channel or output out of range
k_rx_err_invalid_state	Channel not initialized

Precondition

Channel must be initialized via `rx_gptw_init_pwm()`
duty_percent must be a valid non-null pointer

Postcondition

duty_percent contains current duty cycle percentage
No hardware state modified (read-only operation)

Note

Not thread-safe. Caller must provide synchronization.

Example:

```
float duty = 0.0F;
rx_err_t err = rx_gptw_get_duty(k_gptw_channel_0, k_gptw_output_a, &duty);
if (err == k_rx_ok) {
    // duty now contains current duty cycle percentage [0.0, 100.0]
}
```

See also

[rx_gptw_set_duty\(\)](#) Set duty cycle by percentage
[rx_gptw_get_period\(\)](#) Get period count for manual calculation

Since

Version 1.0.0

Get current duty cycle as a floating-point percentage.

Reads the current compare register value (GTCCRA or GTCCRB) from hardware and converts it to a percentage using the cached period from `s_gptw_period[]`.

Algorithm:

$$\text{duty_percent} = \frac{\text{duty_count} \times 100}{\text{period}}$$

Precondition

Channel must be initialized via `rx_gptw_init_*`()
`duty_percent` must point to valid float storage

Postcondition

`*duty_percent` contains duty cycle in `[0.0, 100.0]` on success
Hardware registers unchanged

Note

Returns actual register value; may differ from the last set value if buffer transfer has not yet occurred at period boundary

Not thread-safe: concurrent `rx_gptw_set_duty` calls may cause torn reads

```
float duty;  
rx_err_t err = rx_gptw_get_duty(k_gptw_channel_0, k_gptw_output_a, &duty);
```

Here is the call graph for this function:

8.79.4.6 rx_gptw_get_period()

```

rx_err_t rx_gptw_get_period (
    const rx_gptw_channel_t channel,
    uint32_t * period_count) [nodiscard]

```

Get the 32-bit PWM period count for a GPTW channel.

Reads the GTPR (General Timer Period Register) value for the specified channel. This value determines the PWM frequency and is needed to calculate raw duty counts: $\text{duty_count} = (\text{duty_percent} / 100) * \text{period_count}$.

Parameters

in	channel	GPTW channel number (valid: 0-3)
out	period_count	Pointer to store 32-bit period count

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, period_count written
k_rx_err_null_ptr	period_count is nullptr
k_rx_err_invalid_arg	Channel out of range
k_rx_err_invalid_state	Channel not initialized

Precondition

Channel must be initialized via [rx_gptw_init_pwm\(\)](#)
period_count must be a valid non-null pointer

Postcondition

period_count contains the GTPR register value
No hardware state modified (read-only operation)

Note

Not thread-safe. Caller must provide synchronization.

Example:

```
uint32_t period = 0;
rx_err_t err = rx_gptw_get_period(k_gptw_channel_0, &period);
if (err == k_rx_ok) {
    // Calculate raw duty count for 50% duty cycle
    uint32_t duty_count = (period * k_gptw_duty_50_pct_num) / k_gptw_duty_pct_denom;
}
```

See also

[rx_gptw_set_duty_raw\(\)](#) Uses period_count for raw duty calculation

Since

Version 1.0.0

Get the 32-bit PWM period count for a GPTW channel.

Implementation of [rx_gptw_get_period\(\)](#) - see [rx_gptw.h](#) for complete documentation.

Returns the cached period value from s_gptw_period[], which matches the GTPR register value set during initialization.

Precondition

Channel initialized via `rx_gptw_init_*`()
`period_count` points to valid `uint32_t` storage

Postcondition

`*period_count` contains period value on success

Note

Thread-safe: Reads from cached value, not hardware
 Useful for calculating raw duty counts from percentages

```
01244 {
01245   RX_CHECK_NULL_PTR(period_count, s_tag, "period_count pointer is nullptr");
01246
01247   if (((int32_t)channel >= (int32_t)k_gptw_max_channels) || !s_gptw_initialized[channel]) {
01248       return k_rx_err_invalid_state;
01249   }
01250
01251   *period_count = s_gptw_period[channel];
01252   return k_rx_ok;
01253 }
```

References [k_gptw_max_channels](#), [s_gptw_initialized](#), [s_gptw_period](#), and [s_tag](#).

8.79.4.7 `rx_gptw_init_all_staggered()`

```
rx_err_t rx_gptw_init_all_staggered (
    const rx\_gptw\_config\_t * configs[k_rx_gptw_channel_count]) [nodiscard]
```

Initialize all 4 GPTW channels with 90-degree phase staggering.

Implementation of `rx_gptw_init_all_staggered()` - see [rx_gptw.h](#) for complete documentation with diagrams, examples, and NASA compliance notes.

8.79.4.8 Implementation Overview

1. Validate inputs: NULL check, frequency > 0, valid `wave_mode`
2. Enable module clock: Clear `MSTPCRA.MSTPA7`
3. Stop all channels: Atomic stop via `GTSTPA` register
4. Calculate period: Common period for all channels
5. Configure each channel: Loop calls [internal_configure_channel_staggered\(\)](#)
6. Start all channels: Atomic start via `GTSTRA` register

8.79.4.9 Phase Staggering Benefits

- Reduces peak current by spreading PWM edges across period
- Lowers EMI from simultaneous switching transients
- Allows smaller power supply capacitors

Here is the call graph for this function:

8.79.4.10 rx_gptw_init_pwm()

```
rx_err_t rx_gptw_init_pwm (
    const rx_gptw_channel_t channel,
    const rx_gptw_config_t * config)  [nodiscard]
```

Initialize a single GPTW channel for PWM output.

Configures the specified GPTW channel for PWM mode (sawtooth or triangle wave). Automatically configures MPC for the pin alternate functions, sets up dead-time insertion, and starts PWM generation at 0% duty cycle. The GTCNT counter is reset to zero during initialization.

Parameters

in	channel	GPTW channel number (valid: 0-3)
in	config	Pointer to PWM configuration struct (must be non-null)

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, channel initialized and timer running
k_rx_err_invalid_arg	Channel out of range or config is null
k_rx_err_invalid_state	GPTW module not enabled in MSTPCR

Precondition

GPTW module clock must be enabled

config must point to a valid [rx_gptw_config_t](#)

Postcondition

Channel timer running at configured frequency with 0% duty

GTCNT reset to zero (affects phase staggering if called per-channel)

Note

Not thread-safe. Call from single-threaded init context.

Warning

Resets GTCNT to 0. If phase staggering is required, use [rx_gptw_init_all_staggered\(\)](#) instead, or configure phase offsets after all channels are initialized.

See also

[rx_gptw_init_all_staggered\(\)](#) Phase-staggered multi-channel init
[rx_gptw_deinit\(\)](#) Release channel resources

Since

Version 1.0.0

Initialize a single GPTW channel for PWM output.

Configures one GPTW channel for PWM generation. This function performs complete hardware setup including module clock enable, MPC configuration, port pin setup, timer configuration, and automatic timer start. For 4-motor systems, prefer [rx_gptw_init_all_staggered\(\)](#) instead.

8.79.4.11 Initialization Sequence

1. Validate config pointer ([RX_CHECK_NULL_PTR](#))
2. Validate channel range [0-3]
3. Get channel register base address
4. Calculate period from frequency and wave mode
5. Enable GPTW module clock ([MSTPCRA.MSTPA7](#))
6. Stop timer if already running
7. Configure GPTW hardware registers ([GTCR](#), [GTIOR](#), [GTPR](#), etc.)
8. Configure MPC for Port E alternate function
9. Configure port pins ([PMR](#), [PDR](#))
10. Store period value and set initialized flag
11. Start timer

Precondition

System clock configured ([PCLKA](#) = 120 MHz)
Port E pins not used by other peripherals

Postcondition

GPTW channel configured and running
Duty cycle initialized to 0%
MPC and port pins configured

Invariant

[s_gptw_initialized\[channel\]](#) == true on success
[s_gptw_period\[channel\]](#) contains valid period on success

Note

Not thread-safe: Call once during system initialization

Timer starts automatically - use [rx_gptw_stop\(\)](#) to halt if needed

Warning

Calling while channel is running will cause glitches

Attention

For 4-motor systems, use [rx_gptw_init_all_staggered\(\)](#) instead

Performance:

- Execution time: ~50 us at 240 MHz
- Memory: 0 bytes heap, ~32 bytes stack

Example (Single Channel for LED PWM):

```
rx_gptw_config_t led_config = {
    .frequency_hz = 1000,
    .deadtime_ns = 0,
    .wave_mode = k_gptw_wave_saw_pwm,
    .enable_complementary = false,
    .invert_polarity = false
};

rx_err_t err = rx_gptw_init_pwm(k_gptw_channel_0, &led_config);
if (err == k_rx_ok) {
    rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
        rx_gptw_output_id(k_gptw_output_a), 50.0f);
}
```

Here is the call graph for this function:

8.79.4.12 rx`gptw`output`id()

```

rx_gptw_output_id_t rx_gptw_output_id (
    rx_gptw_output_t value)  [inline], [static]
  
```

Helper to construct a GPTW output wrapper.

Provides type-safe wrapper construction with NASA Power of 10 Rule 5 validation (minimum 2 checks per function):

- Pre-condition: Input value is within valid output range [A-B]
- Post-condition: Wrapper correctly stores the input value

Parameters

in	value	GPTW output enum value (k_gptw_output_a or k_gptw_output_b)
----	-------	---

Returns

Wrapped output ID for type-safe function calls

Precondition

value must be a valid [rx_gptw_output_t](#) (k_gptw_output_a or k_gptw_output_b)

Caller must pass a compile-time known or previously validated output value

Postcondition

Returned wrapper .value field equals the input value

Wrapper is immediately usable in any API accepting [rx_gptw_output_id_t](#)

Note

Reentrant and lock-free; contains no shared mutable state

See also

[rx_gptw_channel_id\(\)](#) Companion wrapper constructor for channel parameter

[rx_gptw_output_id_t](#) Wrapper type constructed by this function

Since

Version 1.0.0

Definition at line 599 of file [rx_gptw.h](#).

```
00600 {
00601     /* Pre-condition: output must be in valid range */
00602     /* Note: value >= k_gptw_output_a is always true for uint8_t since k_gptw_output_a == 0 */
00603     RX_ASSERT(value <= k_gptw_output_b, "GPTW output out of range");
00604
00605     const rx_gptw_output_id_t id = {.value = value};
00606
00607     return id;
00608 }
```

References [k_gptw_output_b](#).

8.79.4.13 rx_gptw_set_duty()

```
rx_err_t rx_gptw_set_duty (
    const rx_gptw_channel_id_t channel,
    const rx_gptw_output_id_t output,
    const float duty_percent) [nodiscard]
```

Set PWM duty cycle (floating-point percentage).

Updates the duty cycle for the specified GPTW channel and output. The new duty cycle is written to the compare register buffer and takes effect on the next PWM period boundary, ensuring glitch-free operation.

8.79.4.14 Algorithm Steps

1. Validate channel and output wrapper values
2. Check channel is initialized
3. Clamp duty_percent to [0.0, 100.0] range
4. Calculate raw count: $\text{duty_count} = (\text{duty_percent} / 100.0) \times \text{period_count}$
5. Write to compare register (GTCCRA or GTCCRB)
6. Register buffer transfers to active on next period boundary

Duty Cycle Calculation:

$$\text{duty_count} = \left\lfloor \frac{\text{duty_percent}}{100} \times \text{period_count} \right\rfloor$$

For 20 kHz PWM with 120 MHz PCLKA:

- Period count = 6000
- 50% duty = 3000 counts
- Resolution = 0.0167% per count

Parameters

in	channel	GPTW channel wrapped in rx_gptw_channel_id_t for type safety • Use <code>rx_gptw_channel_id(k_gptw_channel_0)</code> through <code>rx_gptw_channel_id(k_gptw_channel_3)</code>
in	output	Output selection wrapped in rx_gptw_output_id_t for type safety • Use <code>rx_gptw_output_id(k_gptw_output_a)</code> or <code>rx_gptw_output_id(k_gptw_output_b)</code>
in	duty_percent	Duty cycle in percent [0.0, 100.0] • Values < 0.0 are clamped to 0.0 • Values > 100.0 are clamped to 100.0 • NaN and infinity are treated as invalid

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Duty cycle updated successfully
<code>k_rx_err_invalid_arg</code>	Channel or output out of range, or duty is NaN/infinity
<code>k_rx_err_not_initialized</code>	Channel not initialized via <code>rx_gptw_init_*</code> ()

Precondition

Channel initialized via `rx_gptw_init_all_staggered()` or `rx_gptw_init_pwm()`
 duty_percent is a valid float (not NaN or infinity)

Postcondition

Compare register updated with new duty value
 Duty takes effect on next period boundary (no glitch)

Invariant

Actual duty always in [0%, 100%] regardless of input

Note

Thread-safe: Atomic register write, safe from ISR or multiple threads
 Use `rx_gptw_set_duty_raw()` in tight control loops to avoid float overhead

Warning

Floating-point calculation adds ~4 us overhead vs raw version

Performance:

- Execution time: ~5 us at 240 MHz (includes float multiply)
- Memory usage: 0 bytes heap, ~16 bytes stack

Example (Set Motor Speed):

```
// Set motor 0 forward at 75% speed
// Output A = direction (100% = forward)
rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
  rx_gptw_output_id(k_gptw_output_a),
  100.0F);

// Output B = speed (75% duty)
rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
  rx_gptw_output_id(k_gptw_output_b),
  75.0F);
```

Example (PID Control Loop):

```
void motor_control_task(void)
{
    while (true) {
        float setpoint = get_velocity_setpoint();
        float measured = read_encoder_velocity();
        float output;

        rx_pid_compute(&pid, setpoint, measured, 0.01F, &output);

        // Convert PID output (-100 to +100) to duty cycle
        float duty = fabsf(output);
        bool forward = (output >= 0.0F);

        // Set direction
        rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
                        rx_gptw_output_id(k_gptw_output_a),
                        forward ? 100.0F : 0.0F);

        // Set speed
        rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
                        rx_gptw_output_id(k_gptw_output_b),
                        duty);

        tx_thread_sleep(1); // 100 Hz control loop
    }
}
```

Since

Version 1.0.0

NASA Power of 10 Compliance:

- Rule 5: [OK] 2 preconditions, 2 postconditions
- Rule 7: [OK] Returns error code, caller must check

Set PWM duty cycle (floating-point percentage).

Converts floating-point duty percentage [0.0, 100.0] to raw count value and delegates to [rx_gptw_set_duty_raw\(\)](#) for hardware register update. The compare register (GTCCRA or GTCCRB) is written and the change takes effect on the next PWM period boundary (glitch-free via buffer mode).

Algorithm:

$$\text{duty_count} = \left\lfloor \frac{\text{duty_percent} \times \text{period}}{100} \right\rfloor$$

Precondition

Channel must be initialized via [rx_gptw_init_*](#)()
duty_percent must be in [0.0, 100.0]

Postcondition

Compare register written; change takes effect next period boundary
 Motor output drive updated on next PWM cycle

Note

Not thread-safe: concurrent writes to same output cause undefined behavior

```
rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
                rx_gptw_output_id(k_gptw_output_a), 75.0f);
```

Here is the call graph for this function:

8.79.4.15 rx_gptw_set_duty_raw()

```
rx_err_t rx_gptw_set_duty_raw (
    const rx_gptw_channel_t channel,
    rx_gptw_output_t output,
    uint32_t duty_count) [nodiscard]
```

Set PWM duty cycle using raw counter value.

Updates duty cycle using a raw counter value for efficiency in tight control loops where floating-point overhead should be avoided. The count is written to the compare register buffer and takes effect on the next PWM period boundary, ensuring glitch-free operation.

Parameters

in	channel	GPTW channel (valid: 0-3)
in	output	Output channel (k_gptw_output_a or k_gptw_output_b)
in	duty_count	Duty cycle count (valid range: 0 to period_count)

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, duty cycle updated
k_rx_err_invalid_arg	Channel, output, or count out of range
k_rx_err_invalid_state	Channel not initialized via rx_gptw_init_pwm()

Precondition

Channel must be initialized via rx_gptw_init_pwm()

duty_count must not exceed the period count for the channel

Postcondition

Compare register buffer updated with new duty count

Active register updated on next period boundary

Note

Thread-safe: single 32-bit register write is inherently atomic on RX72N

Performance:

Constant time: single 32-bit register write after validation.

Example:

```
// Read current period, compute 75% duty, then set raw count
uint32_t period = 0;
rx_err_t err = rx_gptw_get_period(k_gptw_channel_0, &period);
if (err == k_rx_ok) {
    const uint32_t duty_count = (period * k_gptw_duty_75_pct_num) / k_gptw_duty_pct_denom;
    err = rx_gptw_set_duty_raw(k_gptw_channel_0, k_gptw_output_b, duty_count);
}
```

See also

[rx_gptw_set_duty\(\)](#) Percentage-based version with float conversion

[rx_gptw_get_period\(\)](#) Query period count for duty calculation

Since

Version 1.0.0

Set PWM duty cycle using raw counter value.

Directly writes duty_count to the compare register (GTCCRA or GTCCRB). Buffer mode (enabled during init via GTBER) ensures the update takes effect on the next PWM period boundary without glitches. Values exceeding the period are clamped to period (100% duty).

Register Access:

- Output A: Writes to GTCCRA
- Output B: Writes to GTCCRB

Precondition

Channel must be initialized via rx_gptw_init_*

duty_count should be in [0, period] for meaningful duty; higher values clamped

Postcondition

GTCCRA or GTCCRB written with clamped duty_count

Change takes effect at next PWM period boundary

Note

Not thread-safe: concurrent writes to the same register cause undefined behavior

Values exceeding period are silently clamped to period

```
uint32_t period;
rx_gptw_get_period(k_gptw_channel_0, &period);
rx_gptw_set_duty_raw(k_gptw_channel_0, k_gptw_output_a, period / 2U); // 50%
```

Here is the caller graph for this function:

8.79.4.16 rx_gptw_start()

```
rx_err_t rx_gptw_start (
    const rx_gptw_channel_t channel) [nodiscard]
```

Start the GPTW timer counter for PWM generation.

Sets the GTCR.CST bit to begin counting. The timer is automatically started during [rx_gptw_init_pwm\(\)](#), but can be stopped via [rx_gptw_stop\(\)](#) and restarted with this function. Counting resumes from the current GTCNT value (not reset to zero).

Parameters

in	channel	GPTW channel number (valid: 0-3)
----	---------	----------------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, timer started
k_rx_err_invalid_arg	Channel out of range

Precondition

Channel must be initialized via [rx_gptw_init_pwm\(\)](#)

Channel must currently be stopped (safe to call if already running)

Postcondition

Timer counter incrementing at peripheral clock rate

PWM outputs active (if enabled via [rx_gptw_enable_output\(\)](#))

Note

Not thread-safe. Caller must provide synchronization.

Example:

```
// Restart timer after a stop
rx_err_t err = rx_gptw_start(k_gptw_channel_0);
if (err != k_rx_ok) {
    // Handle start failure
}
```

See also

[rx_gptw_stop\(\)](#) Stop the timer counter

[rx_gptw_init_pwm\(\)](#) Initializes and starts timer automatically

Since

Version 1.0.0

Start the GPTW timer counter for PWM generation.

Implementation of [rx_gptw_start\(\)](#) - see [rx_gptw.h](#) for complete documentation.

Sets the Count Start (CST) bit in GTCR to begin counter operation. The timer will count according to the configured waveform mode (sawtooth or triangle) and generate PWM output on the enabled pins.

8.79.4.17 Register Access

1. Unlock write protection (GTWP)
2. Set GTCR.CST bit
3. Lock write protection (GTWP)

Precondition

Channel configured via `rx_gptw_init_*`() (recommended)

Postcondition

Timer counting actively

PWM output generated on enabled pins

Note

Does NOT require channel to be "initialized" (no flag check)

Timer automatically started during `rx_gptw_init_*`()

Idempotent: Safe to call when already running

Referenced by `rx_gptw_init_pwm()`.

Here is the call graph for this function:

Here is the caller graph for this function:

8.79.4.18 rx_gptw_stop()

```
rx_err_t rx_gptw_stop (
    const rx_gptw_channel_t channel) [nodiscard]
```

Stop the GPTW timer counter.

Clears the GTCR.CST bit to halt counting. PWM outputs hold their last state when the timer stops. The GTCNT value is preserved and counting resumes from that value when `rx_gptw_start()` is called.

Parameters

in	channel	GPTW channel number (valid: 0-3)
----	---------	----------------------------------

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Success, timer stopped
<code>k_rx_err_invalid_arg</code>	Channel out of range

Precondition

Channel must be initialized via `rx_gptw_init_pwm()`

Channel should be running (safe to call if already stopped)

Postcondition

Timer counter halted at current GTCNT value
PWM outputs frozen at last driven state

Note

Not thread-safe. Caller must provide synchronization.

Warning

Outputs hold last state; explicitly set duty to 0 before stopping if low output is required.

Example:

```
// Stop timer and ensure outputs are low
rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
                rx_gptw_output_id(k_gptw_output_b), 0.0F);
rx_err_t err = rx_gptw_stop(k_gptw_channel_0);
```

See also

[rx_gptw_start\(\)](#) Resume timer counter
[rx_gptw_deinit\(\)](#) Full shutdown including output disable

Since

Version 1.0.0

Stop the GPTW timer counter.

Implementation of [rx_gptw_stop\(\)](#) - see [rx_gptw.h](#) for complete documentation.

Clears the Count Start (CST) bit in GTCR to halt counter operation. The timer counter value (GTCNT) is preserved and PWM outputs hold their current state.

8.79.4.19 Register Access

1. Unlock write protection (GTWP)
2. Clear GTCR.CST bit
3. Lock write protection (GTWP)

Precondition

None (can be called on uninitialized channel)

Postcondition

Timer stopped (GTCR.CST = 0)
 Counter value preserved (GTCNT unchanged)
 Output pins hold last state

Note

Does NOT require channel to be "initialized" (no flag check)
 Idempotent: Safe to call when already stopped
 For safety shutdown, also disable outputs via [rx_gptw_enable_output\(\)](#)

Warning

Outputs may remain HIGH when stopped - disable outputs for safe state

00001 /**
00002  * @file rx_gptw.h
00003  * @brief GPTW PWM Driver for RX72N Motor Control
00004  *
00005  * @details
00006  * **Production-grade PWM driver** for the RX72N General PWM Timer (GPTW) peripheral,
00007  * optimized for brushed DC motor control with H-bridge drivers. This module provides
00008  * high-resolution 32-bit PWM generation with complementary outputs, deadtime insertion,
00009  * and phase-staggered operation for 4-motor systems.
00010  *
00011  * ## Purpose and Design Rationale
00012  *
00013  * The GPTW peripheral is chosen over MTU for motor control because:
00014  * 1. **32-bit resolution** - Higher precision than MTU's 16-bit (0.000015% vs 0.0015%)
00015  * 2. **Dedicated motor pins** - Port E pins optimized for PWM output
00016  * 3. **Hardware deadtime** - Prevents H-bridge shoot-through without CPU overhead
00017  * 4. **Phase staggering** - Reduces peak current draw and EMI
00018  *
00019  * ## Key Features
00020  *
00021  * **PWM Generation**:
00022  * - 4 independent channels (GPTW0-GPTW3) for 4 motors
00023  * - 32-bit counter resolution for precise duty cycle control
00024  * - Sawtooth (edge-aligned) or triangle (center-aligned) waveforms
00025  * - Complementary A/B outputs per channel for H-bridge control
00026  * - Configurable deadtime insertion (0-65535 ns)
00027  *
00028  * **Phase Staggering**:
00029  * - 90-degree phase offset between channels
00030  * - Channel 0: 0deg, Channel 1: 90deg, Channel 2: 180deg, Channel 3: 270deg
00031  * - Spreads current draw across PWM period
00032  * - Reduces peak power supply current by ~75%
00033  * - Reduces conducted EMI by preventing simultaneous switching
00034  *
00035  * **Motor Control Integration**:
00036  * - Direct interface with DRV8263H H-bridge drivers
00037  * - IN2/IN1 control mode support (sign-magnitude)
00038  * - Glitch-free duty cycle updates on period boundary
00039  * - Fast raw duty cycle API for tight control loops
00040  *
00041  * ## Hardware Architecture
00042  *
00043  * @par Pin Assignments (from hardware_pinout.h):
00044  *
00045  * | Motor | Channel | Output A | Output B | Function |
00046  * |-----|-----|-----|-----|-----|
00047  * | Motor 0 | GPTW0 | PE5/GTIOC0A | PE2/GTIOC0B | Front-Left |

00068  * | Counter Resolution | 8.33 ns | 1/120MHz |
00069  * | PWM Frequency | 20 kHz | Typical for motor control |
00070  * | Period Counts | 6000 | 120MHz / 20kHz |
00071  * | Duty Resolution | 0.0167% | 1/6000 |
00072  *
00073  * ## PWM Waveform Modes
00074  *
00075  * @dot
00076  * digraph waveform_modes {
00077  *   rankdir=LR;
00078  *   node [shape=box, style=rounded];
00079  *
00080  *   subgraph cluster_saw {
00081  *     label="Sawtooth (Edge-Aligned)";
00082  *     saw_desc [label="Counter: 0->Period->0\nUpdate: At trough\nBest for: Simple PWM"];

```

```

00083 * }
00084 *
00085 * subgraph cluster_tri {
00086 *     label="Triangle (Center-Aligned)";
00087 *     tri_desc [label="Counter: 0->Period->0->Period\nUpdate: At crest/trough\nBest for: Motor control"];
00088 * }
00089 * }
00090 * @enddot
00091 *
00092 * ## Performance Characteristics
00093 *
00094 * | Operation | Execution Time | Memory Usage | Notes |
00095 * |-----|-----|-----|-----|
00096 * | rx_gptw_init_all_staggered() | ~100 us | 0 heap | One-time setup |
00097 * | rx_gptw_set_duty() | ~5 us | 0 | Float calculation |
00098 * | rx_gptw_set_duty_raw() | ~1 us | 0 | Direct register write |
00099 * | rx_gptw_get_duty() | ~3 us | 0 | Register read + calc |
00100 * | rx_gptw_enable_output() | ~1 us | 0 | Single register write |
00101 *
00102 * **Memory Footprint**:
00103 * - Static variables: ~64 bytes (initialization flags, period cache)
00104 * - Code size: ~2 KB (all functions)
00105 * - Stack usage: < 64 bytes (deepest call)
00106 * - Heap usage: 0 bytes (zero dynamic allocation)
00107 *
00108 * ## Thread Safety and RTOS Integration
00109 *
00110 * **Thread-Safe Operations**:
00111 * - rx_gptw_set_duty() and rx_gptw_set_duty_raw() are atomic register writes
00112 * - Safe to call from motor control ISR or ThreadX tasks
00113 * - No mutex required for duty cycle updates
00114 *
00115 * **Non-Thread-Safe Operations**:
00116 * - rx_gptw_init_all_staggered() - Call once during system initialization
00117 * - rx_gptw_deinit() - Call only when no motor control active
00118 *
00119 * @par Hardware Requirements:
00120 *
00121 * | Component | Requirement | Notes |
00122 * |-----|-----|-----|
00123 * | MCU | Renesas RX72N | GPTW peripheral required |
00124 * | Clock | PCLKA @ 120 MHz | System clock configuration |
00125 * | Pins | Port E (PE0-PE7) | Configured via MPC |
00126 * | Power | 3.3V I/O | LVCMOS compatible |
00127 *
00128 * @par Module Dependencies:
00129 *
00130 * **This module depends on**:
00131 * - `rx_err.h` - Error code definitions
00132 * - `rx_check.h` - Parameter validation macros
00133 * - `rx72n_gptw_regs.h` - GPTW register definitions
00134 * - `rx72n_mpc_regs.h` - Pin mux configuration
00135 *
00136 * **This module is used by**:
00137 * - `rx_motor.c` - Motor control driver
00138 * - `rx_drv8263.c` - H-bridge driver interface
00139 * - `motor_control_task.c` - Motor control task
00140 *
00141 * @par NASA Power of 10 Compliance:
00142 *
00143 * | Rule | Status | Implementation |
00144 * |-----|-----|-----|
00145 * | 1. Simple control flow | [OK] | No goto/setjmp/recursion |
00146 * | 2. Fixed loop bounds | [OK] | Loops bounded by k_gptw_channel_3 (4 iterations max) |
00147 * | 3. No dynamic allocation | [OK] | Zero malloc/free, all static |
00148 * | 4. Small functions | [OK] | All functions < 60 lines |
00149 * | 5. Assertions (>=2 per function) | [OK] | Minimum 2 validation checks per function |
00150 * | 6. Narrow scope | [OK] | File-scope statics, minimal globals |
00151 * | 7. Check return values | [OK] | All functions return rx_err_t |
00152 * | 8. Limited preprocessor | [OK] | C23 typed enums, minimal macros |
00153 * | 9. Pointer restrictions | [OK] | Single-level pointers only |
00154 * | 10. Compiler warnings | [OK] | Compiles with -Wall -Wextra -Werror |
00155 *
00156 * @par SOLID Principles:
00157 *
00158 * **Single Responsibility (S)**:
00159 * - This module handles ONLY GPTW PWM generation
00160 * - Motor control logic is in rx_motor.c
00161 * - H-bridge configuration is in rx_drv8263.c
00162 *
00163 * **Open/Closed (O)**:
00164 * - Extensible via rx_gptw_config_t structure
00165 * - New waveform modes can be added without modifying existing code
00166 * - Frequency and deadtime configurable at runtime
00167 *
00168 * **Liskov Substitution (L)**:
00169 * - All functions return rx_err_t with consistent semantics

```

```

00170 * - Channel and output parameters are validated uniformly
00171 *
00172 * **Interface Segregation (I)**:
00173 * - Separate functions for float vs raw duty cycle
00174 * - Init, set, get, enable are independent operations
00175 * - Wrapper types prevent parameter swapping
00176 *
00177 * **Dependency Inversion (D)**:
00178 * - Depends on abstract error codes, not specific implementations
00179 * - Motor control depends on this interface, not hardware registers directly
00180 *
00181 * @see rx_motor.h Motor control driver using GPTW
00182 * @see rx_drv8263.h H-bridge driver interface
00183 * @see rx72n_gptw_regs.h Register definitions
00184 * @see RX72N Hardware Manual Section 26 - General PWM Timer
00185 * @see docs/sections/03_hardware_pinout.tex Pin assignments

00210
00211 /**
00212 * @enum rx_gptw_channel_t
00213 * @brief GPTW Channel Identifiers for 4-Motor Control System
00214 *
00215 * @details
00216 * Identifies the four GPTW timer channels used for motor PWM generation.
00217 * Each channel controls one motor through complementary A/B outputs connected
00218 * to a DRV8263H H-bridge driver.
00219 *
00220 * ## Channel Architecture
00221 *
00222 * Each GPTW channel provides:
00223 * - 32-bit up/down counter
00224 * - Two compare/capture registers (GTCCRA, GTCCRB)
00225 * - Two output pins (GTIOCnA, GTIOCnB)
00226 * - Independent deadtime insertion
00227 * - Synchronized start/stop capability
00228 *
00229 * @par Channel-to-Motor Mapping:
00230 *
00231 * | Channel | Motor | Position | Register Base | Phase Offset |
00232 * |-----|-----|-----|-----|-----|
00233 * | GPTW0 | Motor 0 | Front-Left | 0x000C2100 | 0deg |
00234 * | GPTW1 | Motor 1 | Front-Right | 0x000C2180 | 90deg |
00235 * | GPTW2 | Motor 2 | Rear-Left | 0x000C2200 | 180deg |
00236 * | GPTW3 | Motor 3 | Rear-Right | 0x000C2280 | 270deg |
00237 *
00238 * @par Pin Assignments:
00239 *
00240 * | Channel | Output A | Output B | MPC Setting |
00241 * |-----|-----|-----|-----|
00242 * | k_gptw_channel_0 | PE5/GTIOC0A | PE2/GTIOC0B | PSEL = 0x1E |
00243 * | k_gptw_channel_1 | PE4/GTIOC1A | PE1/GTIOC1B | PSEL = 0x1E |
00244 * | k_gptw_channel_2 | PE3/GTIOC2A | PE0/GTIOC2B | PSEL = 0x1E |
00245 * | k_gptw_channel_3 | PE7/GTIOC3A | PE6/GTIOC3B | PSEL = 0x1E |
00246 *
00247 * @par Usage Example:
00248 * @code{.c}
00249 * // Initialize all channels with staggered phases
00250 * rx_gptw_config_t config = {
00251 *     .frequency_hz = 20000,
00252 *     .deadtime_ns = 1000,
00253 *     .wave_mode = k_gptw_wave_saw_pwm,
00254 *     .enable_complementary = true,

```

```

00255 *     .invert_polarity = false
00256 * };
00257 * rx_gptw_init_all_staggered(&config);
00258 *
00259 * // Set duty cycle for motor 0 (front-left)
00260 * rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
00261 *                 rx_gptw_output_id(k_gptw_output_a),
00262 *                 50.0F); // 50% duty cycle
00263 * @endcode
00264 *
00265 * @invariant Channel values are contiguous: 0, 1, 2, 3
00266 * @invariant All channels use same register structure (0x80 byte spacing)
00267 * @invariant Channel count equals motor count (4)
00268 *
00269 * @note C23 typed enum with uint8_t underlying type (1-byte values)
00270 * @note Channel 4 and 5 exist in hardware but are not used in STAR
00271 *
00272 * @see rx_gptw_channel_id() Type-safe wrapper constructor
00273 * @see rx_gptw_output_t Output selection within channel
00274 * @see rx72n_gptw_regs.h Register structure definitions
00275 *
00276 * @since Version 1.0.0
00277 */
00278 typedef enum : uint8_t {
00279     k_gptw_channel_0 =
00280         0, /**< GPTW0 channel for Motor 0 (Front-Left). Register base: 0x000C2100. Outputs: PE5/GTIOC0A,
00281            PE2/GTIOC0B. Phase offset: 0deg in staggered mode */
00282     k_gptw_channel_1 =
00283         1, /**< GPTW1 channel for Motor 1 (Front-Right). Register base: 0x000C2180. Outputs: PE4/GTIOC1A,
00284            PE1/GTIOC1B. Phase offset: 90deg in staggered mode */
00285     k_gptw_channel_2 =
00286         2, /**< GPTW2 channel for Motor 2 (Rear-Left). Register base: 0x000C2200. Outputs: PE3/GTIOC2A,
00287            PE0/GTIOC2B. Phase offset: 180deg in staggered mode */
00288     k_gptw_channel_3 =
00289         3, /**< GPTW3 channel for Motor 3 (Rear-Right). Register base: 0x000C2280. Outputs: PE7/GTIOC3A,
00290            PE6/GTIOC3B. Phase offset: 270deg in staggered mode */
00291 } rx_gptw_channel_t;
00292
00293 /**
00294 * @enum rx_gptw_output_t
00295 * @brief GPTW Output Channel Selection for Complementary PWM
00296 *
00297 * @details
00298 * Selects between the two outputs (A and B) available on each GPTW channel.
00299 * Each output has an independent duty cycle and is controlled separately.
00300 *
00301 * ## Independent Output Mode (STAR Configuration)
00302 *
00303 * For the DRV8263H motor driver in IN2/IN1 mode, the GPTW outputs operate
00304 * independently** (not in complementary mode). Each output has its own
00305 * compare register and duty cycle:
00306 * - Output A: Static direction signal (0% or 100% duty)
00307 * - Output B: Variable-duty PWM for speed control
00308 *
00309 * The outputs are NOT inverted versions of each other and no hardware
00310 * deadtime insertion is used. This is safe because the DRV8263H has
00311 * integrated shoot-through protection on its internal H-bridge FETs.
00312 *
00313 * ## IN2/IN1 Mode (Sign-Magnitude)
00314 *
00315 * For DRV8263H H-bridge control in IN2/IN1 mode:
00316 * - Output A: Connected to IN2 (direction) input - controls direction
00317 * - Output B: Connected to IN1 (PWM) input - controls PWM duty
00318 *
00319 * @par H-Bridge Connection:
00320 *
00321 * | Output | DRV8263H Pin | Function | Signal Type |
00322 * |-----|-----|-----|-----|
00323 * | Output A (GTIOCnA) | IN2 | Direction control | Static HIGH/LOW |
00324 * | Output B (GTIOCnB) | IN1 | PWM speed control | PWM waveform |
00325 *
00326 * @par Usage Example:
00327 * @code{.c}
00328 * // Set forward direction at 75% duty for motor 0
00329 * // Output A = HIGH (forward direction)
00330 * rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
00331 *                 rx_gptw_output_id(k_gptw_output_a),
00332 *                 100.0F); // IN2 = HIGH (direction)
00333 *
00334 * // Output B = PWM at 75% (motor speed)
00335 * rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
00336 *                 rx_gptw_output_id(k_gptw_output_b),
00337 *                 75.0F); // IN1 = 75% PWM
00338 *
00339 * // Reverse direction: set Output A LOW
00340 * rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
00341 *                 rx_gptw_output_id(k_gptw_output_a),

```

```

00338 *          0.0F); // IN2 = LOW (reverse)
00339 * @endcode
00340 *
00341 * @invariant Output values are 0 (A) or 1 (B) only
00342 * @invariant Both outputs available on all channels
00343 *
00344 * @note C23 typed enum with uint8_t underlying type
00345 * @warning In independent mode, each output is controlled separately; the
00346 *          DRV8263H handles shoot-through protection internally
00347 *
00348 * @see rx_gptw_output_id() Type-safe wrapper constructor
00349 * @see rx_gptw_channel_t Channel selection
00350 * @see rx_drv8263.h H-bridge driver interface
00351 *
00352 * @since Version 1.0.0
00353 */
00354 typedef enum : uint8_t {
00355     k_gptw_output_a =
00356         0, /**< GTIOCA output pin. Connected to DRV8263H IN2 (direction) in IN2/IN1 mode. Controls motor direction:
            HIGH=forward, LOW=reverse */
00357     k_gptw_output_b =
00358         1, /**< GTIOCB output pin. Connected to DRV8263H IN1 (PWM) in IN2/IN1 mode. PWM duty cycle controls motor
            speed (0-100%) */
00359 } rx_gptw_output_t;

00362 * @enum rx_gptw_wave_mode_t
00363 * @brief GPTW PWM Waveform Mode Selection
00364 *
00365 * @details
00366 * Selects the PWM waveform generation mode. The mode determines counter behavior,
00367 * output alignment, and duty cycle update timing. Motor control typically uses
00368 * sawtooth (edge-aligned) or triangle (center-aligned) modes.
00369 *
00370 * ## Waveform Comparison
00371 *
00372 * **Sawtooth (Edge-Aligned)**:
00373 * - Counter counts up from 0 to period, then resets to 0
00374 * - PWM edges aligned to period start
00375 * - Simpler timing, lower switching losses
00376 * - Asymmetric current ripple
00377 *
00378 * **Triangle (Center-Aligned)**:
00379 * - Counter counts up to period, then down to 0
00380 * - PWM pulses centered in period
00381 * - Symmetric current ripple (better for motors)
00382 * - Reduced EMI due to staggered edges
00383 *
00384 * @dot
00385 * digraph waveform_comparison {
00386 *     rankdir=TB;
00387 *     node [shape=record, fontsize=10];

00389 *     sawtooth [label="{Sawtooth Mode|Counter: 0..P repeats|Update: trough only|PWM edges: aligned to start|Best for:
            LED dimming}"];
00390 *     triangle [label="{Triangle Mode|Counter: 0..P.0 repeats|Update: crest and/or trough|PWM edges: centered|Best for:
            motor control}"];
00391 *
00392 *     sawtooth -> triangle [style=invis];
00393 * }
00394 * @enddot
00395 *
00396 * @par Mode Selection Guide:
00397 *
00398 * | Mode | Counter Pattern | Update Timing | Use Case |
00399 * |-----|-----|-----|-----|
00400 * | k_gptw_wave_saw_pwm | 0->P->0 (reset) | Trough | Simple PWM, LEDs |
00401 * | k_gptw_wave_tri_pwm1 | 0->P->0 (fold) | Trough | Motor control (standard) |
00402 * | k_gptw_wave_tri_pwm2 | 0->P->0 (fold) | Crest+Trough | Motor control (fast update) |
00403 * | k_gptw_wave_tri_pwm3 | 0->P->0 (fold) | 64-bit at trough | High-precision motor |
00404 *
00405 * @par Mathematical Model:
00406 *
00407 * **Sawtooth PWM Frequency**:
00408 * @f[
00409 *     f_{PWM} = \frac{f_{PCLKA}}{(GTPR + 1)}
00410 * @f]
00411 *
00412 * **Triangle PWM Frequency** (half the sawtooth frequency for same period):
00413 * @f[
00414 *     f_{PWM} = \frac{f_{PCLKA}}{2 \times (GTPR + 1)}
00415 * @f]
00416 *
00417 * Where:
00418 * - @f f_{PCLKA} @f = 120 MHz (peripheral clock)
00419 * - @f GTPR @f = Period register value
00420 *

```

```

00421 * @par Usage Example:
00422 * @code{.c}
00423 * // Configure for motor control with triangle wave (center-aligned)
00424 * rx_gptw_config_t config = {
00425 *     .frequency_hz = 20000,    // 20 kHz PWM
00426 *     .deadtime_ns = 1000,     // 1 us deadtime
00427 *     .wave_mode = k_gptw_wave_tri_pwm1, // Triangle, trough update
00428 *     .enable_complementary = true,
00429 *     .invert_polarity = false
00430 * };
00431 *
00432 * // For simple LED dimming, use sawtooth
00433 * rx_gptw_config_t led_config = {
00434 *     .frequency_hz = 1000,     // 1 kHz (no audible noise)
00435 *     .wave_mode = k_gptw_wave_saw_pwm, // Sawtooth (simpler)
00436 *     .enable_complementary = false,
00437 *     .invert_polarity = false
00438 * };
00439 * @endcode
00440 *
00441 * @invariant Mode values map directly to GTCR.MD bit field (0-3)
00442 * @invariant All modes support complementary output with deadtime
00443 *
00444 * @note C23 typed enum with uint8_t underlying type
00445 * @note Triangle modes have half the effective PWM frequency for same period
00446 *
00447 * @see RX72N Hardware Manual Section 26.2.12 (GTCR.MD bits)
00448 * @see rx_gptw_config_t Configuration structure using this enum

00611 * @struct rx_gptw_config_t
00612 * @brief GPTW PWM Configuration Structure
00613 *
00614 * @details
00615 * Contains all configuration parameters for initializing a GPTW channel
00616 * for PWM output. This structure is passed to rx_gptw_init_pwm() or
00617 * rx_gptw_init_all_staggered() to configure the timer.
00618 *
00619 * ## Configuration Guidelines
00620 *
00621 * **Frequency Selection**:
00622 * - Motor control: 15-25 kHz (above audible range, efficient switching)
00623 * - LED dimming: 100-1000 Hz (no flicker, simple filtering)
00624 * - Servo control: 50-400 Hz (standard RC servo range)
00625 *
00626 * **Deadtime Selection**:
00627 * - Minimum: 100 ns (propagation delay margin)
00628 * - Typical: 500-1000 ns (good balance)
00629 * - Maximum: 5000 ns (very conservative, reduces efficiency)
00630 *
00631 * @par Configuration Parameter Table:
00632 *
00633 * | Parameter | Min | Max | Default | Unit | Notes |
00634 * |-----|-----|-----|-----|-----|-----|
00635 * | frequency_hz | 100 | 1000000 | 20000 | Hz | Limited by PCLKA/2 |
00636 * | deadtime_ns | 0 | 65535 | 1000 | ns | 0 disables deadtime |
00637 * | wave_mode | 0 | 3 | 0 | enum | See rx_gptw_wave_mode_t |
00638 * | enable_complementary | false | true | true | bool | For H-bridge |
00639 * | invert_polarity | false | true | false | bool | Active-low output |
00640 *
00641 * @par Memory Layout:
00642 *
00643 * | Offset | Size | Field | Type | Alignment |
00644 * |-----|-----|-----|-----|-----|
00645 * | 0 | 4 | frequency_hz | uint32_t | 4 |
00646 * | 4 | 2 | deadtime_ns | uint16_t | 2 |
00647 * | 6 | 1 | wave_mode | uint8_t | 1 |
00648 * | 7 | 1 | enable_complementary | bool | 1 |
00649 * | 8 | 1 | invert_polarity | bool | 1 |
00650 * | 9-11 | 3 | (padding) | - | - |
00651 * | **Total** | **12** | - | - | **4** |
00652 *
00653 * @par Usage Example (Motor Control):
00654 * @code{.c}
00655 * // Standard motor control configuration
00656 * rx_gptw_config_t motor_config = {
00657 *     .frequency_hz = 20000, // 20 kHz (inaudible)
00658 *     .deadtime_ns = 1000, // 1 us deadtime
00659 *     .wave_mode = k_gptw_wave_saw_pwm, // Edge-aligned
00660 *     .enable_complementary = true, // H-bridge requires this
00661 *     .invert_polarity = false // Active-high outputs
00662 * };
00663 *
00664 * rx_err_t err = rx_gptw_init_all_staggered(&motor_config);
00665 * if (err != k_rx_ok) {
00666 *     rx_log_error("GPTW", "Failed to initialize: %d", err);
00667 * }
00668 * @endcode
00669 *
00670 * @par Usage Example (LED Dimming):
00671 * @code{.c}
00672 * // LED PWM configuration (no complementary needed)
00673 * rx_gptw_config_t led_config = {
00674 *     .frequency_hz = 1000, // 1 kHz (no flicker)
00675 *     .deadtime_ns = 0, // No deadtime for LEDs
00676 *     .wave_mode = k_gptw_wave_saw_pwm,
00677 *     .enable_complementary = false, // Single output only

```

```

00678 *   .invert_polarity = false
00679 * };
00680 *
00681 * rx_err_t err = rx_gptw_init_pwm(k_gptw_channel_0, &led_config);
00682 * @endcode
00683 *
00684 * @invariant frequency_hz > 0 (enforced by rx_gptw_init_*)
00685 * @invariant frequency_hz <= PCLKA / 2 (Nyquist limit)
00686 * @invariant wave_mode in [0, 3] (valid enum range)
00687 *
00688 * @note Structure is copied during initialization; no need to keep alive
00689 * @warning Invalid configurations rejected with k_rx_err_invalid_arg
00690 *
00691 * @see rx_gptw_init_pwm() Single channel initialization

00801  * @brief Initialize all 4 GPTW channels with 90 degree phase staggering
00802  *
00803  * @details
00804  * Configures GPTW0-3 for synchronized PWM operation with phase offsets that
00805  * spread current draw across the PWM period. This is the **recommended
00806  * initialization function** for 4-motor systems as it reduces peak current
00807  * and EMI compared to synchronized PWM.
00808  *
00809  * ## Phase Staggering Architecture
00810  *
00811  * Phase staggering offsets the start of each channel's PWM period:
00812  * - **Channel 0**: 0deg (reference phase)
00813  * - **Channel 1**: 90deg (period / 4 offset)
00814  * - **Channel 2**: 180deg (period / 2 offset)
00815  * - **Channel 3**: 270deg (3 x period / 4 offset)
00816  *
00817  * @dot
00818  * digraph phase_stagger {
00819  *   rankdir=TB;
00820  *   node [shape=record, fontsize=10];
00821  *
00822  *   title [label="Phase Staggered PWM (4 channels at 50% duty)", shape=none];
00823  *
00824  *   ch0 [label="{Ch0 (0deg)|#####}"];
00825  *   ch1 [label="{Ch1 (90deg)|#####}"];
00826  *   ch2 [label="{Ch2 (180deg)|#####}"];
00827  *   ch3 [label="{Ch3 (270deg)|#####}"];
00828  *   current [label="{Total Current|Spread evenly across period}"];
00829  *
00830  *   title -> ch0 [style=invis];
00831  *   ch0 -> ch1 -> ch2 -> ch3 -> current;
00832  * }
00833  * @enddot
00834  *
00835  * ## Benefits of Phase Staggering
00836  *
00837  * 1. **Reduced Peak Current**: Instead of all motors switching simultaneously,
00838  *   current draw is spread across the period, reducing peak by up to 75%
00839  * 2. **Lower EMI**: Staggered edges reduce conducted emissions
00840  * 3. **Smaller Capacitors**: Lower peak current allows smaller power supply capacitors
00841  * 4. **Better Power Quality**: More constant current draw improves voltage regulation
00842  *
00843  * ## Algorithm Steps
00844  *
00845  * 1. Validate configuration parameters (NULL check, frequency range, wave mode)
00846  * 2. Calculate period count from frequency and PCLKA
00847  * 3. Enable GPTW module clock (MSTPCRA.MSTPA7 = 0)
00848  * 4. Configure MPC for Port E pins (GTIOC function select)
00849  * 5. For each channel (0-3):

```

```

00850 *   a. Configure timer mode register (GTCR)
00851 *   b. Set period register (GTPR)
00852 *   c. Calculate and set phase offset (GTCNT initial value)
00853 *   d. Configure output mode and polarity (GTIOR)
00854 *   e. Set deadtime registers (GTDVU, GTDVD)
00855 *   f. Set initial duty cycle to 0% (GTCCRA, GTCCRB)
00856 * 6. Start all channels simultaneously (GTSTR)
00857
00858 * @param[in] config Common configuration for all channels
00859 * - config->frequency_hz: PWM frequency [100, 1000000] Hz
00860 * - config->deadtime_ns: Deadtime [0, 65535] ns
00861 * - config->wave_mode: Waveform mode (sawtooth or triangle)
00862 * - config->enable_complementary: Enable A/B complementary outputs
00863 * - config->invert_polarity: Invert output polarity
00864

01006 * @brief Set PWM duty cycle (floating-point percentage)
01007 *
01008 * @details
01009 * Updates the duty cycle for the specified GPTW channel and output. The new duty
01010 * cycle is written to the compare register buffer and takes effect on the next
01011 * PWM period boundary, ensuring glitch-free operation.
01012 *
01013 * ## Algorithm Steps
01014 *
01015 * 1. Validate channel and output wrapper values
01016 * 2. Check channel is initialized
01017 * 3. Clamp duty_percent to [0.0, 100.0] range
01018 * 4. Calculate raw count: duty_count = (duty_percent / 100.0) x period_count
01019 * 5. Write to compare register (GTCCRA or GTCCRB)
01020 * 6. Register buffer transfers to active on next period boundary
01021 *
01022 * @par Duty Cycle Calculation:
01023 * @f[

```

```

01024 * \text{duty\_count} = \left\lfloor \frac{\text{duty\_percent}}{100} \right\rfloor \times \text{period\_count} \right\rfloor
01025 * @f]
01026 *
01027 * For 20 kHz PWM with 120 MHz PCLKA:
01028 * - Period count = 6000
01029 * - 50% duty = 3000 counts
01030 * - Resolution = 0.0167% per count
01031 *
01032 * @param[in] channel GPTW channel wrapped in rx_gptw_channel_id_t for type safety
01033 * - Use rx_gptw_channel_id(k_gptw_channel_0) through rx_gptw_channel_id(k_gptw_channel_3)
01034 * @param[in] output Output selection wrapped in rx_gptw_output_id_t for type safety
01035 * - Use rx_gptw_output_id(k_gptw_output_a) or rx_gptw_output_id(k_gptw_output_b)
01036 * @param[in] duty_percent Duty cycle in percent [0.0, 100.0]
01037 * - Values < 0.0 are clamped to 0.0
01038 * - Values > 100.0 are clamped to 100.0
01039 * - NaN and infinity are treated as invalid
01040 *
01041 * @return rx_err_t Error code
01042 * @retval k_rx_ok Duty cycle updated successfully

Enumerations

- enum `rx_iwdt_timeout_t` : `uint16_t` {
`k_iwdt_timeout_128ms`, `k_iwdt_timeout_512ms`, `k_iwdt_timeout_1000ms`, `k_iwdt_timeout_2048ms`,
`k_iwdt_timeout_8192ms`, `k_iwdt_timeout_16384ms` }
 IWDT Timeout Period Options.
- enum `rx_iwdt_reset_cause_t` : `uint8_t` { `k_iwdt_reset_none` , `k_iwdt_reset_underflow` ,
`k_iwdt_reset_refresh_error` }
 IWDT Reset Cause Information.
- enum `rx_iwdt_limits_t` : `uint8_t` { `k_iwdt_max_tasks` = 8 }
 Maximum number of tasks that can be monitored.

Functions

- `rx_err_t rx_hal_iwdt_init` (`uint32_t timeout_ms`)
 Initialize the Independent Watchdog Timer.
- `void rx_hal_iwdt_feed` (`void`)
 Feed (refresh) the watchdog timer.
- `bool rx_hal_iwdt_was_reset` (`void`)
 Check if last reset was caused by watchdog timeout.
- `rx_iwdt_reset_cause_t rx_hal_iwdt_get_reset_cause` (`void`)
 Get detailed reset cause from IWDT.
- `void rx_hal_iwdt_clear_status` (`void`)
 Clear watchdog status flags.
- `rx_err_t rx_hal_iwdt_register_task` (`const char *task_name`, `uint32_t timeout_ms`)
 Register a task for heartbeat monitoring.
- `void rx_hal_iwdt_task_heartbeat` (`const char *task_name`)
 Record a task heartbeat.
- `rx_err_t rx_hal_iwdt_check_tasks` (`void`)
 Check for task deadlocks.
- `const char * rx_hal_iwdt_get_failed_task` (`void`)
 Get the name of the last failed task (if any).

8.81.1 Detailed Description

Independent Watchdog Timer (IWDT) HAL Driver for RX72N.

Hardware Abstraction Layer for the RX72N Independent Watchdog Timer (IWDT) peripheral. This driver provides low-level register access and task-level monitoring for safety-critical system recovery.

8.81.1.1 Purpose and Design Rationale

The IWDT provides true clock-independent watchdog functionality:

- Dedicated 120 kHz on-chip oscillator (IWDTCCLK)
- Operates even if main system clock fails
- Cannot be disabled once started (hardware safety feature)
- Triggers system reset on timeout

This module is the HAL layer providing direct hardware access. For higher-level watchdog features (state-dependent timeouts, comprehensive task monitoring), see rx_core/inc/rx_iwdt.h.

8.81.1.2 Key Features

Hardware Watchdog:

- Internal 120 kHz clock source (IWDTCCLK)
- Configurable timeout: 128ms to 16,384ms
- Window mode (optional, disabled by default)
- Reset or NMI on timeout
- Refresh error detection

Task Monitoring:

- Register up to 8 tasks for heartbeat monitoring
- Per-task timeout configuration
- Failed task identification for diagnostics

8.81.1.3 Hardware Architecture

Clock and Timing:

Parameter	Value	Notes
Clock Source	IWDTCCLK	Internal RC oscillator
Clock Frequency	120 kHz	+/-1% accuracy
Clock Period	8.33 us	1/120kHz
Counter Width	14-bit	Down-counter
Min Timeout	128 ms	$2^{14} / (120k / 1)$
Max Timeout	16,384 ms	$2^{14} / (120k / 128)$

Register Map:

Register	Address	Description
IWDTRR	0x00088030	Refresh register
IWDTR\{r}	0x00088032	Control register
IWDTSR	0x00088034	Status register
IWDTR\{r}	0x00088036	Reset control register
IWDTCSTPR	0x00088038	Count stop register

Timeout Calculation:

$$T_{timeout} = \frac{2^{14} \times \text{TOPS}}{f_{IWDTCCLK}}$$

Where TOPS is the timeout period setting (1, 4, 16, 32, 64, or 128).

8.81.1.4 Sub-clock Pin Handling

The IWDTC uses the internal IWDTCCLK, not the sub-clock oscillator. When sub-clock is unused:

- XCIN: Connect to VSS (ground) via pull-down resistor
- XCOUT: Leave open (unconnected)

System initialization disables sub-clock via SOSC\{r}.SOSTP = 1.

8.81.1.5 Performance Characteristics

Operation	Execution Time	Notes
rx_hal_iwdt_init()	~20 us	One-time configuration
rx_hal_iwdt_feed()	~1 us	Two register writes
rx_hal_iwdt_task_heartbeat()	~3 us	Timestamp update
rx_hal_iwdt_check_tasks()	~5 us x N tasks	Linear scan

Memory Footprint:

- Static variables: ~256 bytes (task tracking)
- Code size: ~1 KB
- Stack usage: < 32 bytes
- Heap usage: 0 bytes

Hardware Requirements:

Component	Requirement	Notes
MCU	Renesas RX72N	IWDT peripheral
Clock	IWDTCLK	120 kHz internal
XCIN Pin	VSS via resistor	When sub-clock unused
XCOU Pin	Open	When sub-clock unused

Module Dependencies:

This module depends on:

- `rx_err.h` - Error code definitions
- [rx72n_iwdt_regs.h](#) - IWDT register definitions

This module is used by:

- `main.c` - System initialization
- All RTOS tasks - Heartbeat reporting
- `rx_core/inc/rx_iwdt.h` - Higher-level watchdog features

NASA Power of 10 Compliance:

Rule	Status	Implementation
1. Simple control flow	↔ [OK]↔	No goto/setjmp/recursion
2. Fixed loop bounds	↔ [OK]↔	Loops bounded by <code>k_iwdt_max_tasks</code> (8)
3. No dynamic allocation	↔ [OK]↔	Static task array only
4. Small functions	↔ [OK]↔	All < 60 lines
5. Assertions	↔ [OK]↔	Minimum 2 checks per function

Rule	Status	Implementation
6. Narrow scope	↔ [OK]↔	File-scope statics
7. Check return values	↔ [OK]↔	All return rx_err_t
8. Limited preprocessor	↔ [OK]↔	C23 typed enums only
9. Pointer restrictions	↔ [OK]↔	Single-level pointers
10. Compiler warnings	↔ [OK]↔	-Wall -Wextra -Werror

SOLID Principles:

Single Responsibility (S):

- HAL layer: Hardware register access only
- Task monitoring separate from hardware watchdog

Open/Closed (O):

- Timeout values configurable
- Task monitoring extensible

Dependency Inversion (D):

- Higher-level rx_core/inc/rx_iwdt.h depends on this HAL interface

Version 1.0.0

Definition in file [rx_hal_iwdt.h](#).

8.81.2 Enumeration Type Documentation

8.81.2.1 rx_iwdt_limits_t

```
enum rx_iwdt_limits_t : uint8_t
```

Maximum number of tasks that can be monitored.

Enumerator

k_iwdt_max_tasks	Support up to 8 monitored tasks
------------------	---------------------------------

Definition at line 403 of file [rx_hal_iwdt.h](#).

```
00403         : uint8_t {
00404     k_iwdt_max_tasks = 8, /**< Support up to 8 monitored tasks */
00405 } rx_iwdt_limits_t;
```

8.81.2.2 rx_iwdt_reset_cause_t

```
enum rx_iwdt_reset_cause_t : uint8_t
```

IWDT Reset Cause Information.

Identifies the specific cause of an IWDT-triggered reset. This information is read from the IWDTSR status register and can be used for post-mortem diagnostics and logging.

8.81.2.3 Reset Cause Detection

At startup, read the reset cause before calling [rx_hal_iwdt_init\(\)](#):

```
void startup_diagnostics(void)
{
    rx_iwdt_reset_cause_t cause = rx_hal_iwdt_get_reset_cause();

    switch (cause) {
    case k_iwdt_reset_none:
        uart_debug_puts("Normal startup\\r\\n");
        break;
    case k_iwdt_reset_underflow:
        uart_debug_puts("[WARN] Watchdog timeout - task deadlock?\\r\\n");
        log_failed_task(rx_hal_iwdt_get_failed_task());
        break;
    case k_iwdt_reset_refresh_error:
        uart_debug_puts("[ERROR] Watchdog refresh error - code bug\\r\\n");
        break;
    }

    rx_hal_iwdt_clear_status();
}
```

Reset Cause Table:

Cause	IWDTSR Bits	Meaning	Typical Issue
None	0x0000	Not a watchdog reset	Power-on, external reset
Underflow	UNDF=1	Counter reached zero	Task deadlock, infinite loop

Cause	IWDTSR Bits	Meaning	Typical Issue
Refresh Error	REFEF=1	Invalid refresh	Window violation, wrong sequence

Invariant

Values map to IWDTSR bit patterns

`k_iwdt_reset_none` (0) is the default for non-watchdog resets

Note

C23 typed enum with `uint8_t` underlying type

See also

[`rx\_hal\_iwdt\_get\_reset\_cause\(\)`](#) Read the reset cause

Since

Version 1.0.0

Enumerator

<code>k_iwdt_reset_none</code>	No watchdog reset occurred. System reset was from power-on, external reset pin, or other source. <code>IWDTSR.UNDFF=0</code> , <code>REFEF=0</code>
<code>k_iwdt_reset_underflow</code>	Reset due to counter underflow. Counter reached zero before <code>rx_hal_iwdt_feed()</code> was called. Indicates task deadlock or infinite loop. <code>IWDTSR.UNDFF=1</code>
<code>k_iwdt_reset_refresh_error</code>	Reset due to invalid refresh. Either wrong refresh sequence (not 0x00, 0xFF) or refresh during window-prohibited period. <code>IWDTSR.REFEF=1</code>

Definition at line 276 of file [rx_hal_iwdt.h](#).

```

00276         : uint8_t {
00277     k_iwdt_reset_none =
00278         0, /**< No watchdog reset occurred. System reset was from power-on, external reset pin, or other source.
IWDTSR.UNDFF=0, REFEF=0 */
00279     k_iwdt_reset_underflow =
00280         1, /**< Reset due to counter underflow. Counter reached zero before rx_hal_iwdt_feed() was called. Indicates task
deadlock or infinite loop. IWDTSR.UNDFF=1 */
00281     k_iwdt_reset_refresh_error =
00282         2, /**< Reset due to invalid refresh. Either wrong refresh sequence (not 0x00, 0xFF) or refresh during
window-prohibited period. IWDTSR.REFEF=1 */
00283 } rx_iwdt_reset_cause_t;
```

8.81.2.4 rx_iwdt_timeout_t

```
enum rx_iwdt_timeout_t : uint16_t
```

IWDT Timeout Period Options.

Pre-defined timeout periods for the IWDT. These values correspond to hardware divider settings that produce specific timeout durations from the 120 kHz `IWDTCLK`.

8.81.2.5 Timeout Selection Guide

Timeout	Use Case	Notes
128ms	High-frequency control loops (> 50 Hz)	Very responsive
512ms	Normal control loops (10-50 Hz)	Fast detection
1000ms	Default - typical applications	Good balance
2048ms	Low-frequency tasks (1-10 Hz)	Tolerant
8192ms	Slow background operations	Long timeout
16384ms	Initialization/maintenance	Maximum

Timeout Calculation:

Timeout periods are derived from:

$$T = \frac{\text{Cycle Count}}{f_{IWDTCLK}} = \frac{\text{Cycle Count}}{120 \text{ kHz}}$$

Usage Example:

```
// Use predefined timeout for 1 second
rx_hal_iwdt_init(k_iwdt_timeout_1000ms);

// Or use custom value (rounded up to nearest supported)
rx_hal_iwdt_init(500); // Rounds to 512ms
```

Invariant

All values are in milliseconds

Values correspond to hardware divider settings

Note

C23 typed enum with uint16_t underlying type

Actual timeout may vary +/-1% due to oscillator tolerance

Since

Version 1.0.0

Enumerator

k_iwdt_timeout_128ms	Minimum timeout (128ms). Use for high-frequency control loops requiring fast failure detection. TOPS=1 divider
k_iwdt_timeout_512ms	Short timeout (512ms). Use for normal control loops (10-50 Hz). Provides good responsiveness. TOPS=4 divider

k_iwdt_timeout_1000ms	Default timeout (1 second). Recommended for typical applications. Good balance between detection speed and tolerance. TOPS~8
k_iwdt_timeout_2048ms	Medium timeout (2 seconds). Use for low-frequency tasks that may have variable execution time. TOPS=16 divider
k_iwdt_timeout_8192ms	Long timeout (8 seconds). Use for slow background operations or maintenance tasks. TOPS=64 divider
k_iwdt_timeout_16384ms	Maximum timeout (~16 seconds). Use only for initialization phases or very slow operations. TOPS=128 divider

Definition at line 209 of file [rx_hal_iwdt.h](#).

```

00209     : uint16_t {
00210     k_iwdt_timeout_128ms =
00211         128, /**< Minimum timeout (128ms). Use for high-frequency control loops requiring fast failure detection. TOPS=1
            divider */
00212     k_iwdt_timeout_512ms =
00213         512, /**< Short timeout (512ms). Use for normal control loops (10-50 Hz). Provides good responsiveness. TOPS=4
            divider */
00214     k_iwdt_timeout_1000ms =
00215         1000, /**< Default timeout (1 second). **Recommended** for typical applications. Good balance between detection
            speed and tolerance. TOPS=8 */
00216     k_iwdt_timeout_2048ms =
00217         2048, /**< Medium timeout (2 seconds). Use for low-frequency tasks that may have variable execution time. TOPS=16
            divider */
00218     k_iwdt_timeout_8192ms =
00219         8192, /**< Long timeout (8 seconds). Use for slow background operations or maintenance tasks. TOPS=64 divider */
00220     k_iwdt_timeout_16384ms =
00221         16384, /**< Maximum timeout (~16 seconds). Use only for initialization phases or very slow operations. TOPS=128
            divider */
00222 } rx_iwdt_timeout_t;

```

8.81.3 Function Documentation

8.81.3.1 rx_hal_iwdt_clear_status()

```
void rx_hal_iwdt_clear_status (
    void )
```

Clear watchdog status flags.

Clears the underflow and refresh error flags in IWDTSR. Call after reading the reset cause to prepare for next reset detection.

Note

Flags are typically cleared once at startup after logging the cause.

Clears the UNDF (underflow) and REFE (refresh error) flags in the IWDT Status Register. These flags are "write-0-to-clear" type - writing 0 to a flag clears it, writing 1 has no effect.

Clear Sequence

- * 1. Read IWDTSR (get current status)
- * 2. AND with ~(UNDF | REFE) to clear both flags
- * 3. Write back to IWDTSR
- *
- * Note: Read-modify-write is safe because flags are write-0-to-clear
- *

Precondition

Status has been read via [rx_hal_iwdt_was_reset\(\)](#) or [rx_hal_iwdt_get_reset_cause\(\)](#)

Postcondition

UNDFE flag cleared

REFE flag cleared

Note

On host builds, function is a no-op

Call after reading status at startup to prepare for next reset

Example:

```
// Startup diagnostic sequence
if (rx_hal_iwdt_was_reset()) {
    rx_iwdt_reset_cause_t cause = rx_hal_iwdt_get_reset_cause();
    log_watchdog_reset(cause);
}
// Clear flags so next reset can be detected
rx_hal_iwdt_clear_status();
```

See also

Here is the call graph for this function:

8.81.3.2 rx_hal_iwdt_feed()

```
void rx_hal_iwdt_feed (
    void )
```

Feed (refresh) the watchdog timer.

Resets the watchdog counter to prevent timeout. This function must be called periodically, within the configured timeout period.

The refresh sequence writes 0x00 followed by 0xFF to the IWDTRR register. This sequence must complete atomically without interruption.

Note

Call this function from your main control loop.

Calling more frequently than needed has no negative effect.

Do NOT call from interrupt handlers unless you understand the implications for your system's safety.

Example placement:

```
// Motor control task at 100 Hz (10ms period)
// With 1000ms timeout, we have 100 chances to feed
void motor_control_task_entry(ULONG input) {
    while (1) {
        read_sensors();
        update_pid();
        set_motor_output();
        rx_hal_iwdt_feed(); // Feed at end of each iteration
        tx_thread_sleep(1); // 10ms at 100Hz tick
    }
}
```

Feed (refresh) the watchdog timer.

Performs the IWDT refresh sequence by writing the magic values 0x00 then 0xFF to the IWDTRR register. This resets the down-counter to its initial value, preventing timeout and system reset.

Refresh Sequence (Atomic Operation)

```
* +-----+
* | 1. Disable interrupts (save PSW) |
* | 2. Write 0x00 to IWDTRR         |
* | 3. Write 0xFF to IWDTRR         |
* | 4. Restore interrupt state      |
* +-----+
* \\CRITICAL: Steps 2 and 3 must not be interrupted!
*
```

Timing Requirements

- * - Execution time: ~2 us including interrupt disable/enable
- * - Must be called faster than configured timeout period
- * - Typical call rate: Every 100-500 ms depending on timeout
- *

Precondition

IWDTRR must be initialized via [rx_hal_iwdt_init\(\)](#)

Called at rate faster than configured timeout

Postcondition

IWDT counter reset to initial value
 Interrupt state restored to previous value

Note

Safe to call from ISRs (uses atomic disable/restore)
 On host builds, function is a no-op

Warning

Incomplete refresh sequence causes refresh error -> system reset
 Missing calls to this function cause timeout -> system reset

Example:

```
// Main supervision loop
while (1) {
    // Check all tasks for deadlock
    rx_err_t err = rx_hal_iwdt_check_tasks();
    if (err == k_rx_ok) {
        // All tasks healthy, feed hardware watchdog
        rx_hal_iwdt_feed();
    }
    // If task timeout detected, DON'T feed - let watchdog reset
    tx_thread_sleep(100); // 100 ms check interval
}
```

Here is the call graph for this function:

Here is the caller graph for this function:

8.81.3.3 rx_hal_iwdt_get_reset_cause()

```

rx_iwdt_reset_cause_t rx_hal_iwdt_get_reset_cause (
    void )

```

Get detailed reset cause from IWDT.

Provides more detailed information about what caused a watchdog reset:

- Underflow: Counter reached zero (normal timeout)
- Refresh error: Invalid refresh sequence or window violation

Returns

Reset cause enumeration

Note

This provides more detail than [rx_hal_iwdt_was_reset\(\)](#) for diagnostics.

Get detailed reset cause from IWDT.

Reads the IWDT Status Register to determine the specific cause of the last watchdog reset. Refresh errors take priority over underflow since they indicate a software bug in the refresh sequence.

Reset Cause Priority

- * 1. Refresh Error (REFEF=1): Invalid refresh sequence
- * - Incomplete 0x00/0xFF write
- * - Write occurred outside window (if window mode enabled)
- * 2. Underflow (UNDF=1): Counter reached zero
- * - rx_hal_iwdt_feed() not called within timeout period
- * - Software hang, deadlock, or infinite loop
- * 3. None: No watchdog reset occurred
- * - Power-on reset, external reset, or other cause
- *

Precondition

Can be called before [rx_hal_iwdt_init\(\)](#)

Status flags preserved across reset

Postcondition

Status flags NOT cleared (call [rx_hal_iwdt_clear_status\(\)](#) to clear)

Note

On host builds, always returns `k_iwdt_reset_none`

Refresh error has priority over underflow in return value

Example:

```
rx_iwdt_reset_cause_t cause = rx_hal_iwdt_get_reset_cause();
switch (cause) {
    case k_iwdt_reset_refresh_error:
        uart_debug_puts("ERROR: Watchdog refresh sequence error!\r\n");
        break;
    case k_iwdt_reset_underflow:
        uart_debug_puts("WARN: Watchdog timeout - software hang detected\r\n");
        break;
    case k_iwdt_reset_none:
    default:
        uart_debug_puts("Normal startup\r\n");
        break;
}
rx_hal_iwdt_clear_status(); // Clear flags after reading
```

Here is the call graph for this function:

8.81.3.4 rx_hal_iwdt_init()

```
rx_err_t rx_hal_iwdt_init (
    const uint32_t timeout_ms) [nodiscard]
```

Initialize the Independent Watchdog Timer.

Configures IWDT with the specified timeout period. Once started, the watchdog cannot be stopped and must be fed periodically to prevent reset.

Configuration:

- Clock: 120 kHz internal IWDT-dedicated oscillator (IWDTCLK)
- Window mode: Disabled (refresh allowed anytime)
- Action: System reset on timeout
- Count stop in sleep: Disabled (continues counting)

Parameters

in	timeout_ms	Desired timeout in milliseconds. Actual timeout will be rounded up to nearest supported value (128, 512, 1024, 2048, 4096, 8192, or 16384 ms).
----	------------	--

Returns

`k_rx_ok` on success
`k_rx_err_invalid_arg` if timeout is out of supported range
`k_rx_err_invalid_state` if IWDT is already running

Note

This function starts the watchdog - `rx_hal_iwdt_feed()` must be called within the timeout period to prevent reset.

On RX72N, IWDT starts counting after the first refresh operation.

Configures and starts the hardware IWDT with the specified timeout period. Once started, the watchdog cannot be stopped - periodic calls to `rx_hal_iwdt_feed()` are required to prevent system reset.

Initialization Sequence

- * 1. Validate not already initialized
- * 2. Validate timeout_ms within range
- * 3. Look up timeout configuration in table
- * 4. Configure IWDT\|r (timeout period, clock divisor, window)
- * 5. Configure IWDT\|r (reset action - not NMI)
- * 6. Configure IWDT\|r (continue counting in sleep)
- * 7. Perform first refresh (starts the watchdog)
- * 8. Set initialized flag
- *

Point of No Return

- * After step 7 (first refresh), the IWDT is running and CANNOT be stopped.
- * Any failure after this point leaves system in watchdog-protected state.
- *

Precondition

IWDT must not be already initialized
 timeout_ms in range [`k_iwdt_timeout_min_ms`, `k_iwdt_timeout_max_ms`]
 System startup, single-threaded context

Postcondition

IWDT running with selected timeout period
`s_iwdt_initialized` set to `k_iwdt_initialized`
 Periodic `rx_hal_iwdt_feed()` calls now required

Note

On host builds (non-RX), skips hardware access but sets initialized flag
 Actual timeout $\geq$ requested (selected from lookup table)

Warning

Once initialized, IWDT cannot be disabled (requires hard reset)

Must call `rx_hal_iwdt_feed()` faster than timeout period

Example:

```
// Initialize with 2 second timeout
rx_err_t err = rx_hal_iwdt_init(2000);
if (err != k_rx_ok) {
    // Handle error - system cannot start safely
    while (1) { // halt }
}

// Now must feed periodically
while (1) {
    // ... main loop ...
    rx_hal_iwdt_feed(); // Must occur every < 2 seconds
    tx_thread_sleep(100);
}
```

Here is the call graph for this function:

8.81.3.5 rx_hal_iwdt_was_reset()

```

bool rx_hal_iwdt_was_reset (
    void ) [nodiscard]

```

Check if last reset was caused by watchdog timeout.

Reads the IWDT status register to determine if the previous system reset was triggered by the watchdog timer.

Returns

true if watchdog caused the last reset
false if reset was from another source (power-on, external, etc.)

Note

Call this early in startup (before clearing status flags) to log or handle watchdog-induced resets appropriately.

Check if last reset was caused by watchdog timeout.

Reads the IWDTSR Status Register (IWDTSR) to determine if the previous system reset was caused by watchdog timeout (underflow) or refresh error. This function should be called early in startup for diagnostics.

Status Register Flags

- * IWDTSR Bit 14 (UNDF) - Underflow Flag:
 - * - 1: Counter reached 0 (timeout occurred)
 - * - 0: No underflow
- * IWDTSR Bit 15 (REFEF) - Refresh Error Flag:
 - * - 1: Invalid refresh sequence detected
 - * - 0: No refresh error

Precondition

Can be called before `rx_hal_iwdt_init()`
Status flags preserved across reset (hardware feature)

Postcondition

Status flags NOT cleared (call `rx_hal_iwdt_clear_status()` to clear)

Note

On host builds, always returns false
Call `rx_hal_iwdt_get_reset_cause()` for specific cause

Example:

```
// Check at startup
if (rx_hal_iwdt_was_reset()) {
    uart_debug_puts("[WARN] Recovered from watchdog reset!\r\n");
    const char* failed = rx_hal_iwdt_get_failed_task();
    if (failed != nullptr) {
        uart_debug_printf("Failed task: %s\r\n", failed);
    }
}
```

8.82 rx_hal_iwdt.h

[Go to the documentation of this file.](#)

```
00001 /**
00002  * @file rx_hal_iwdt.h
00003  * @brief Independent Watchdog Timer (IWDT) HAL Driver for RX72N
00004  *
00005  * @details
00006  * **Hardware Abstraction Layer** for the RX72N Independent Watchdog Timer (IWDT)
00007  * peripheral. This driver provides low-level register access and task-level
00008  * monitoring for safety-critical system recovery.
00009  *
00010  * ## Purpose and Design Rationale
00011  *
00012  * The IWDT provides **true clock-independent** watchdog functionality:
00013  * - Dedicated 120 kHz on-chip oscillator (IWDTCLK)
00014  * - Operates even if main system clock fails
00015  * - Cannot be disabled once started (hardware safety feature)
00016  * - Triggers system reset on timeout
00017  *
00018  * This module is the **HAL layer** providing direct hardware access. For
00019  * higher-level watchdog features (state-dependent timeouts, comprehensive
00020  * task monitoring), see `rx_core/inc/rx_iwdt.h`.
00021  *
00022  * ## Key Features
00023  *
00024  * **Hardware Watchdog**:
00025  * - Internal 120 kHz clock source (IWDTCLK)
00026  * - Configurable timeout: 128ms to 16,384ms
```

```

00027 * - Window mode (optional, disabled by default)
00028 * - Reset or NMI on timeout
00029 * - Refresh error detection
00030 *
00031 * Task Monitoring:
00032 * - Register up to 8 tasks for heartbeat monitoring
00033 * - Per-task timeout configuration
00034 * - Failed task identification for diagnostics
00035 *
00036 * Hardware Architecture
00037 *
00038 * @par Clock and Timing:
00039 *

00126 * @par SOLID Principles:
00127 *
00128 * **Single Responsibility (S)**:
00129 * - HAL layer: Hardware register access only
00130 * - Task monitoring separate from hardware watchdog
00131 *
00132 * **Open/Closed (O)**:
00133 * - Timeout values configurable
00134 * - Task monitoring extensible
00135 *
00136 * **Dependency Inversion (D)**:
00137 * - Higher-level `rx_core/inc/rx_iwtdt.h` depends on this HAL interface
00138 *
00139 * @see rx_core/inc/rx_iwtdt.h Higher-level watchdog with state management
00140 * @see rx72n_iwtdt_regs.h Register definitions
00141 * @see RX72N Hardware Manual Chapter 35 - Independent Watchdog Timer
00142 *

00165 /**
00166 * @enum rx_iwtdt_timeout_t
00167 * @brief IWDT Timeout Period Options
00168 *
00169 * @details
00170 * Pre-defined timeout periods for the IWDT. These values correspond to
00171 * hardware divider settings that produce specific timeout durations from
00172 * the 120 kHz IWDTCLK.
00173 *
00174 * ## Timeout Selection Guide
00175 *
00176 * | Timeout | Use Case | Notes |
00177 * |-----|-----|-----|
00178 * | 128ms | High-frequency control loops (> 50 Hz) | Very responsive |
00179 * | 512ms | Normal control loops (10-50 Hz) | Fast detection |
00180 * | 1000ms | **Default** - typical applications | Good balance |
00181 * | 2048ms | Low-frequency tasks (1-10 Hz) | Tolerant |
00182 * | 8192ms | Slow background operations | Long timeout |
00183 * | 16384ms | Initialization/maintenance | Maximum |
00184 *
00185 * @par Timeout Calculation:
00186 *
00187 * Timeout periods are derived from:
00188 * @f[
00189 * T = \frac{\text{Cycle Count}}{f_{\text{IWDTCLK}}} = \frac{\text{Cycle Count}}{120\,\text{kHz}}
00190 * @f]
00191 *
00192 * @par Usage Example:
00193 * @code{.c}
00194 * // Use predefined timeout for 1 second
00195 * rx_hal_iwtdt_init(k_iwtdt_timeout_1000ms);
00196 *
00197 * // Or use custom value (rounded up to nearest supported)
00198 * rx_hal_iwtdt_init(500); // Rounds to 512ms

```

```

00199 * @endcode
00200 *
00201 * @invariant All values are in milliseconds
00202 * @invariant Values correspond to hardware divider settings
00203 *
00204 * @note C23 typed enum with uint16_t underlying type
00205 * @note Actual timeout may vary +/-1% due to oscillator tolerance

8.83 libs/rx_hal/inc/rx_host_irq.h File Reference

HOST_IRQ GPIO Output Driver for RPi5 Data-Ready Signaling.

```
#include <stdint.h>
```

```
#include "rx_err.h"
```

Include dependency graph for rx_host_irq.h:

This graph shows which files directly or indirectly include this file:

Functions

- `rx_err_t rx_host_irq_init (void)`
Initialize HOST_IRQ pin as GPIO output (deasserted / HIGH).
- `rx_err_t rx_host_irq_deinit (void)`
Deinitialize HOST_IRQ pin (revert to input).
- `rx_err_t rx_host_irq_assert (void)`
Assert HOST_IRQ (drive LOW to signal data ready).
- `rx_err_t rx_host_irq_deassert (void)`
Deassert HOST_IRQ (drive HIGH, idle state).
- `rx_err_t rx_host_irq_is_asserted (bool *asserted)`
Check if HOST_IRQ is currently asserted.

8.83.1 Detailed Description

HOST_IRQ GPIO Output Driver for RPi5 Data-Ready Signaling.

Manages the HOST_IRQ output pin (P67, pin 98) used to signal the Raspberry Pi 5 host controller that the RX72N has data ready for SPI transfer. The signal is active-low (assert LOW to request attention, deassert HIGH when idle).

8.83.1.1 Hardware Configuration

Parameter	Value
Pin	P67 (PORT6, pin 7, package pin 98)
Direction	Output (RX72N -> RPi5)
Active Level	Active-low (asserted = LOW)
Default State	HIGH (deasserted / idle)
Drive	CMOS push-pull

8.83.1.2 Signaling Protocol

```
RX72N has telemetry data ready
|
rx_host_irq_assert()  -> P67 driven LOW
|
RPI5 detects falling edge on its GPIO
|
RPI5 initiates SPI read
|
rx_host_irq_deassert()  -> P67 driven HIGH
```

NASA Power of 10 Compliance:

- Rule 1: No goto, setjmp, recursion
- Rule 3: No dynamic memory (static variables only)
- Rule 4: All functions < 60 lines
- Rule 5: 2+ validation checks per function
- Rule 7: All return values checked
- Rule 8: C23 typed enums, no magic numbers
- Rule 10: -Wall -Wextra -Werror clean

8.83.2 Function Documentation

8.83.2.1 `rx_host_irq_assert()`

```
rx_err_t rx_host_irq_assert (
    void ) [nodiscard]
```

Assert HOST_IRQ (drive LOW to signal data ready).

Drives P67 LOW to signal the RPi5 that the RX72N has data ready for SPI transfer. The RPi5 should respond by initiating an SPI read.

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Success, pin driven LOW
<code>k_rx_err_invalid_state</code>	Not initialized

Precondition

[rx_host_irq_init\(\)](#) called successfully

Postcondition

P67 driven LOW (active)

Note

Thread-safe: single register write is atomic on RX72N

See also

[rx_host_irq_deassert\(\)](#) Release the signal

Since

Version 1.0.0

Assert HOST_IRQ (drive LOW to signal data ready).

Drives the P67 output LOW to signal the host SoC that the RX72N has data ready or wants attention. HOST_IRQ is an active-low, level-triggered line; the host will continue to see "asserted" until [rx_host_irq_deassert\(\)](#) drives it back HIGH. The function is a single register read-modify-write on PORT6.PODR; no interrupts are touched.

Note

Safe to call from task context. Not protected against concurrent calls; serialize at the application layer.

00154     volatile rx_port_regs_t* p6 = port6();
00155     p6->podr &= (uint8_t)~k_host_irq_pin_mask;
00156
00157     return k_rx_ok;
00158 }
```

References [k_host_irq_pin_mask](#), [rx_port_regs_t::podr](#), [port6\(\)](#), and [s_initialized](#).

Here is the call graph for this function:

8.83.2.2 rx_host_irq_deassert()

```
rx_err_t rx_host_irq_deassert (
    void ) [nodiscard]
```

Deassert HOST_IRQ (drive HIGH, idle state).

Drives P67 HIGH (idle). Call after the RPi5 has completed its SPI read.

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Success, pin driven HIGH
<code>k_rx_err_invalid_state</code>	Not initialized

Precondition

[rx_host_irq_init\(\)](#) called successfully

Postcondition

P67 driven HIGH (idle)

Note

Thread-safe: single register write is atomic on RX72N

See also

[rx_host_irq_assert\(\)](#) Assert the signal

Since

Version 1.0.0

Deassert HOST_IRQ (drive HIGH, idle state).

Drives the P67 output HIGH to release the active-low HOST_IRQ line back to its idle state. Single register read-modify-write on PORT6.PODR; no interrupts touched.

Note

Safe to call from task context. Not protected against concurrent calls; serialize at the application layer.

Definition at line 171 of file [rx_host_irq.c](#).

```
00172 {
00173     if (!s_initialized) {
00174         return k_rx_err_invalid_state;
00175     }
00176
00177     volatile rx_port_regs_t* p6 = port6();
00178     p6->podr |= k_host_irq_pin_mask;
00179
00180     return k_rx_ok;
00181 }
```

References [k_host_irq_pin_mask](#), [rx_port_regs_t::podr](#), [port6\(\)](#), and [s_initialized](#).

Here is the call graph for this function:

8.83.2.3 rx_host_irq_deinit()

```
rx_err_t rx_host_irq_deinit (
    void ) [nodiscard]
```

Deinitialize HOST_IRQ pin (revert to input).

Reverts P67 to input mode (safe default) and deasserts the output.

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Success
<code>k_rx_err_invalid_state</code>	Not initialized

Precondition

[rx_host_irq_init\(\)](#) called successfully

Postcondition

P67 reverted to input, no longer driving

Since

Version 1.0.0

Deinitialize HOST_IRQ pin (revert to input).

Symmetric counterpart to [rx_host_irq_init\(\)](#). Drives P67 high one last time so the line is left in its idle (de-asserted) state, then changes the pin direction back to input, gating off any spurious downstream effects. Clears the `s_initialized` flag so subsequent assert/deassert calls return `k_rx_err_invalid_state`.

Note

Not thread-safe. Serialize all `rx_host_irq_*` operations at the application layer.

Definition at line 114 of file [rx_host_irq.c](#).

```

00115 {
00116     if (!s_initialized) {
00117         rx_log_error(s_tag, "Not initialized");
00118         return k_rx_err_invalid_state;
00119     }
00120
00121     volatile rx_port_regs_t* p6 = port6();
00122
00123     /* Deassert before reverting to input */
00124     p6->podr |= k_host_irq_pin_mask;
00125
00126     /* Revert to input (safe default) */
00127     p6->pdr &= (uint8_t)~k_host_irq_pin_mask;
00128
00129     s_initialized = false;
00130
00131     rx_log_info(s_tag, "HOST_IRQ P67 deinitialized (input)");
00132     return k_rx_ok;
00133 }
```

Here is the call graph for this function:

8.83.2.4 rx_host_irq_init()

```
rx_err_t rx_host_irq_init (
    void ) [nodiscard]
```

Initialize HOST_IRQ pin as GPIO output (deasserted / HIGH).

Configures P67 as a GPIO output in CMOS push-pull mode. Sets the initial output level to HIGH (deasserted / idle). The MPC function select is set to GPIO (not IRQ input).

Initialization steps:

1. Clear PMR bit 7 (GPIO mode, not peripheral)
2. Set PODR bit 7 HIGH (deasserted state)
3. Set PDR bit 7 (output direction)

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, P67 configured as output
k_rx_err_invalid_state	Already initialized

Precondition

P67 not in use by another peripheral (RIIC2 etc.)

Postcondition

P67 configured as GPIO output, driven HIGH

Note

Not thread-safe. Call during system init only.

Here is the call graph for this function:

8.83.2.5 rx_host_irq_is_asserted()

```

rx_err_t rx_host_irq_is_asserted (
    bool * asserted) [nodiscard]

```

Check if HOST_IRQ is currently asserted.

Returns the current state of the HOST_IRQ output.

Parameters

out	asserted	Pointer to store state (true = asserted / LOW)
-----	----------	--

Returns

rx_err_t Error code

Return values

k_rx_ok	Success
k_rx_err_null_ptr	asserted is nullptr

Precondition

`rx_host_irq_init()` called

Postcondition

asserted set to current output state

Note

Thread-safe (reads volatile register)

Since

IRQ Digital Filter Driver API for RX72N.

```
#include <stdint.h>
```

```
#include "rx_err.h"
```

Include dependency graph for rx_irq_filter.h:

This graph shows which files directly or indirectly include this file:

Enumerations

- enum `rx_irq_filter_limits_t` : `uint8_t` { `k_rx_irq_max` = 15 }
IRQ filter limits for RX72N.
- enum `rx_irq_filter_clk_t` : `uint8_t` { `k_irq_filter_pclk_1` = 0 , `k_irq_filter_pclk_8` = 1 , `k_irq_filter_pclk_32` = 2 , `k_irq_filter_pclk_64` = 3 }
IRQ filter clock divisor options for sampling rate control.

Functions

- `rx_err_t rx_irq_filter_enable` (`uint8_t` irq_num, `rx_irq_filter_clk_t` filter_clk)
Enable hardware digital filter on an IRQ pin.
- `rx_err_t rx_irq_filter_disable` (`uint8_t` irq_num)
Disable hardware digital filter on an IRQ pin.
- `rx_err_t rx_irq_filter_is_enabled` (`uint8_t` irq_num, `bool` *enabled)
Check if digital filter is enabled on an IRQ pin.
- `rx_err_t rx_irq_filter_get_clock` (`uint8_t` irq_num, `rx_irq_filter_clk_t` *filter_clk)
Get current filter clock divisor setting for an IRQ.

Variables

- static const `uint8_t` `s_irq_max` = 15U
Maximum valid IRQ number (0-15).

Filter Response Times (PCLKB = 60 MHz)

Divisor	Sample Period	Response Time	Noise Rejection
PCLK/ $\leftarrow$ 1	16.7 ns	50 ns	Minimal
PCLK/ $\leftarrow$ 8	133 ns	400 ns	Fast signals
PCLK/32	533 ns	1.6 μ s	Moderate
PCLK/64	1.07 μ s	3.2 μ s	Buttons/switches

STAR Project Usage

IRQ Pin	Function	Recommended Filter	Notes
IRQ0	E-STOP Button	PCLK/64	Max filtering for safety
IRQ5	USB VBUS	PCLK/32	Moderate noise rejection
IRQ8	Expansion	PCLK/32	General-purpose interrupt

Hardware Requirements

Resource	Requirement	Notes
PCLKB	Active	Filter clock source
ICU	Enabled	Not in module stop

Memory Usage

Category	Size	Notes
Code	~200 bytes	All functions
Static data	0 bytes	No static variables
Stack	8 bytes	Per function call

Thread Safety

Not thread-safe. ICU register access is not atomic. Use mutex protection if filter configuration changes at runtime. Recommended: configure filters once during initialization before starting RTOS.

Usage Example - Basic

```
#include "rx_irq_filter.h"

void configure_interrupts(void)
{
    // Enable maximum filtering on E-STOP button (safety-critical)
    rx_irq_filter_enable(0, k_irq_filter_pclk_64);

    // Enable moderate filtering on VBUS detection
    rx_irq_filter_enable(5, k_irq_filter_pclk_32);

    // Configure ICU for edge detection (separate from filtering)
    // ...
}
```

Usage Example - Dynamic Configuration

```
void adjust_filter_for_mode(bool high_noise_environment)
{
    if (high_noise_environment) {
        // Increase filtering in noisy environments
        rx_irq_filter_enable(8, k_irq_filter_pclk_64);
    } else {
        // Reduce filtering for faster response
        rx_irq_filter_enable(8, k_irq_filter_pclk_8);
    }
}

bool check_filter_config(uint8_t irq_num)
{
    bool enabled;
    rx_irq_filter_clk_t clock;

    rx_irq_filter_is_enabled(irq_num, &enabled);
    rx_irq_filter_get_clock(irq_num, &clock);

    return enabled && (clock == k_irq_filter_pclk_64);
}
```

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, longjmp, recursion
- Rule 2: [OK] No loops (simple register operations)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] All functions < 30 lines
- Rule 5: [OK] Input validation on all functions
- Rule 7: [OK] All return values are error codes
- Rule 8: [OK] C23 typed enums for filter clock options
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

SOLID Principles

- Single Responsibility: Only IRQ filter configuration
- Interface Segregation: Minimal 4-function API

8.85.2 Enumeration Type Documentation

8.85.2.1 rx`irq`filter`clk`t

enum [rx_irq_filter_clk_t](#) : uint8_t

IRQ filter clock divisor options for sampling rate control.

Selects the clock divisor for IRQ digital filter sampling. Higher divisors result in slower sampling, providing more noise rejection but also longer response times to valid transitions.

The digital filter requires 3 consecutive samples at the same level to recognize a valid transition. Total response time = 3 x sample period.

Response Time Calculation

$$T_{response} = 3 \times \frac{1}{f_{PCLKB}/divisor} = \frac{3 \times divisor}{f_{PCLKB}}$$

Filter Characteristics (PCLKB = 60 MHz)

Divisor	Sample Period	Response Time	Best For
/↵ 1	16.7 ns	50 ns	High-speed signals
/↵ 8	133 ns	400 ns	Encoder pulses
/32	533 ns	1.6 us	Sensor interrupts

Divisor	Sample Period	Response Time	Best For
/64	1.07 us	3.2 us	Buttons, switches

Noise Rejection Capability

Noise pulses shorter than 2 x sample period are rejected. For PCLK/64 with PCLKB=60MHz, noise pulses < 2.1us are filtered out.

Note

Register encoding: 2 bits per IRQ in IRQFLTC register

Warning

Lower divisors provide faster response but less noise immunity

```

8.85.2.2 rx`irq`filter`limits`

```
enum rx_irq_filter_limits_t : uint8_t
```

IRQ filter limits for RX72N.

The RX72N ICU supports external IRQ pins IRQ0-IRQ15 (16 total).

Enumerator

k_rx_irq_max	
--------------	--

Definition at line 183 of file [rx_irq_filter.h](#).

```
00183     : uint8_t {
00184     k_rx_irq_max = 15,
00185 } rx_irq_filter_limits_t;
```

8.85.3 Function Documentation

8.85.3.1 rx_irq_filter_disable()

```
rx_err_t rx_irq_filter_disable (
    uint8_t irq_num) [nodiscard]
```

Disable hardware digital filter on an IRQ pin.

Disables the ICU digital filter for the specified IRQ pin. After disabling, the raw unfiltered input signal is passed through to the interrupt detector.

Algorithm Steps

1. Validate irq_num is in range [0, 15]
2. Calculate register index
3. Clear enable bit in IRQFLTE register

Parameters

in	irq_num	IRQ number to configure
		Valid range: [0, 15]

Returns

Error code indicating success or failure

Return values

k_rx_ok	Filter successfully disabled
k_rx_err_invalid_arg	irq_num > 15

Precondition

None (can be called regardless of current filter state)

Postcondition

IRQFLTE bit cleared for this IRQ
Raw input passed to interrupt detector

Note

Clock divisor setting is preserved (unchanged)
Safe to call even if filter was already disabled

Thread Safety

Not thread-safe. ICU register modification is not atomic.

Example

```
// Disable filter for faster response
rx_irq_filter_disable(5);
```

See also

[rx_irq_filter_enable\(\)](#) Enable filter

Since

Version 1.0.0

Clears the filter enable bit in IRQFLTE for the specified IRQ. After disabling, raw unfiltered input passes to interrupt detector.

Note

Clock divisor setting preserved for potential re-enable

See also

[rx_irq_filter.h](#) Full API documentation

Since

Version 1.0.0

Definition at line 236 of file [rx_irq_filter.c](#).

```
00237 {
00238     if (irq_num > k_rx_irq_max) {
00239         return k_rx_err_invalid_arg;
00240     }
00241
00242     #ifdef __RX__
00243     uint8_t reg_idx = irq_num / k_irq_filter_irqs_per_reg;
00244     uint8_t bit_pos = irq_num % k_irq_filter_irqs_per_reg;
00245
00246     /* Clear filter enable bit */
00247     icu()->irqfite[reg_idx] &= (uint8_t) ~(1 « bit_pos);
00248
00249     #endif
00250
00251     return k_rx_ok;
00252 }
```

References [icu\(\)](#), [rx_icu_regs_t::irqfite](#), [k_irq_filter_irqs_per_reg](#), and [k_rx_irq_max](#).

Here is the call graph for this function:

8.85.3.2 rx_irq_filter_enable()

```
rx_err_t rx_irq_filter_enable (
    uint8_t irq_num,
    rx_irq_filter_clk_t filter_clk)  [nodiscard]
```

Enable hardware digital filter on an IRQ pin.

Enables the ICU digital filter for the specified IRQ pin with the given clock divisor. The filter samples the input and requires 3 consecutive samples at the same level to recognize a valid edge transition.

Algorithm Steps

1. Validate irq_num is in range [0, 15]
2. Validate filter_clk is valid divisor
3. Calculate register index (0 for IRQ0-7, 1 for IRQ8-15)
4. Set clock divisor in IRQFLTC register
5. Set enable bit in IRQFLTE register

Parameters

in	irq_num	IRQ number to configure - Valid range: [0, 15] - IRQ0-7 use IRQFLTE[0]/IRQFLTC[0] - IRQ8-15 use IRQFLTE[1]/IRQFLTC[1]
in	filter_clk	Clock divisor for filter sampling - k_irq_filter_pclk_1: Minimal filtering - k_irq_filter_pclk_64: Maximum filtering

Returns

Error code indicating success or failure

Return values

k_rx_ok	Filter successfully enabled
k_rx_err_invalid_arg	irq_num > 15 or filter_clk > k_irq_filter_pclk_64

Precondition

PCLKB clock must be running (filter clock source)
ICU module not in module stop

Postcondition

IRQFLTE bit set for this IRQ
IRQFLTC bits set to specified divisor
Filter immediately active

Note

Filter applies to all edge types (rising, falling, both)
Filter continues operating during software standby
Clock divisor is set before enable to avoid glitches

Warning

Enabling filter adds latency to interrupt response

Thread Safety

Not thread-safe. ICU register modification is not atomic.

Performance

- Execution time: ~200 ns @ 240 MHz
- No blocking operations

Example - E-STOP Button

```
// Maximum filtering for mechanical button debounce
rx_err_t err = rx_irq_filter_enable(0, k_irq_filter_pclk_64);
if (err != k_rx_ok) {
    // Handle error
}
```

See also

[rx_irq_filter_disable\(\)](#) Disable filter
[rx_irq_filter_clk_t](#) Clock divisor options

Since

Version 1.0.0

Configures the ICU filter enable (IRQFLTE) and filter clock (IRQFLTC) registers for the specified IRQ. Sets clock divisor first, then enables the filter to avoid sampling at incorrect rate during transition.

Register Modification Sequence

1. IRQFLTC: Clear and set 2-bit clock field for this IRQ
2. IRQFLTE: Set enable bit for this IRQ

Note

On host (non-RX) builds, validates parameters but skips register access

8.85.3.3 rx'irq'filter'get'clock()

```
rx_err_t rx_irq_filter_get_clock (
    uint8_t irq_num,
    rx_irq_filter_clk_t * filter_clk) [nodiscard]
```

Get current filter clock divisor setting for an IRQ.

Reads the IRQFLTC register to retrieve the current clock divisor setting for the specified IRQ's digital filter.

Parameters

in	irq_num	IRQ number to query Valid range: [0, 15]
out	filter_clk	Pointer to receive clock divisor setting - Returns rx_irq_filter_clk_t value - Must not be nullptr

Returns

Error code indicating success or failure

Return values

k_rx_ok	Clock setting successfully retrieved
k_rx_err_invalid_arg	irq_num > 15 or filter_clk pointer is nullptr

Precondition

filter_clk pointer must be non-NULL

Postcondition

*filter_clk contains current divisor setting
No registers modified (read-only operation)

Note

Returns current setting even if filter is disabled

Thread Safety

Thread-safe for reading. Register read is atomic.

Example

```

rx_irq_filter_clk_t current_clock;
rx_err_t err = rx_irq_filter_get_clock(0, &current_clock);
if (err == k_rx_ok) {
    if (current_clock == k_irq_filter_pclk_64) {
        // Maximum filtering configured
    }
}

```

See also

[rx_irq_filter_enable\(\)](#) Set clock divisor
[rx_irq_filter_clk_t](#) Clock divisor values

Since

Version 1.0.0

Reads the 2-bit clock divisor field from IRQFLTC register for the specified IRQ. Returns the divisor setting even if filter is disabled.

Note

On host builds, always returns k_irq_filter_pclk_1

8.85.3.4 rx'irq'filter'is'enabled()

```
rx_err_t rx_irq_filter_is_enabled (
    uint8_t irq_num,
    bool * enabled) [nodiscard]
```

Check if digital filter is enabled on an IRQ pin.

Reads the IRQFLTE register to determine if the digital filter is currently enabled for the specified IRQ.

Parameters

in	irq_num	IRQ number to query Valid range: [0, 15]
out	enabled	Pointer to receive enable status - true: Filter is enabled - false: Filter is disabled - Must not be nullptr

Returns

Error code indicating success or failure

Return values

k_rx_ok	Status successfully retrieved
k_rx_err_invalid_arg	irq_num > 15 or enabled pointer is nullptr

Precondition

enabled pointer must be non-NULL

Postcondition

*enabled contains current filter state

No registers modified (read-only operation)

Thread Safety

Thread-safe for reading. Register read is atomic.

Example

```
bool filter_active;
rx_err_t err = rx_irq_filter_is_enabled(0, &filter_active);
if (err == k_rx_ok && filter_active) {
    // Filter is active on IRQ0
}
```

See also

[rx_irq_filter_enable\(\)](#) Enable filter
[rx_irq_filter_get_clock\(\)](#) Get clock setting

Since

Version 1.0.0

Reads the IRQFLTE register bit for the specified IRQ to determine current filter enable state.

Note

On host builds, always returns false (filter disabled)

8.85.4 Variable Documentation

8.85.4.1 s_irq_max

```
const uint8_t s_irq_max = 15U [static]
```

Maximum valid IRQ number (0-15).

The RX72N ICU supports 16 external interrupt pins, numbered IRQ0 through IRQ15. This constant defines the maximum valid IRQ number for validation.

Value: 15

Valid IRQ Range: [0, 15

]

Note

Static const rather than enum due to use in comparison operations

Wake-source bits for deep software standby.

Functions

- `rx_err_t rx_lpc_init` (void)
Initialize the Low Power Consumption driver.
- `rx_err_t rx_lpc_set_operating_power` (`rx_lpc_opcc_mode_t` mode)
Select the operating power control (OPCCR) mode.
- `rx_err_t rx_lpc_enter_sleep` (void)
Enter Sleep mode (CPU stop, peripherals run).
- `rx_err_t rx_lpc_enter_software_standby` (void)
Enter Software Standby mode.
- `rx_err_t rx_lpc_enter_deep_software_standby` (`uint32_t` wake_mask, `rx_lpc_deep_power_t` deep_power, bool keep_io)
Enter Deep Software Standby mode.
- bool `rx_lpc_was_deep_standby_wake` (void)
Query whether the last reset was caused by a deep-standby wake.
- `rx_err_t rx_lpc_get_wake_flags` (`uint32_t` *flags)
Read the deep-standby wake flags (DPSIFR0..DPSIFR3).

8.87.1 Detailed Description

Low Power Consumption (LPC) HAL Driver for RX72N.

Hardware Abstraction Layer for the RX72N Low Power Consumption subsystem. Provides a small, auditable API for entering the three RX72N low-power modes and for selecting the operating power control mode that governs active-run current.

8.87.1.1 Supported Modes (RX72N Manual Chapter 11)

Mode	CPU	Peripherals	RAM	Wake Latency	Exit Vector
Sleep	Stop	Run	Retained	ns	Continue next PC
Software Standby	Stop	Stop	Retained	us	Continue next PC
Deep Software Standby	Stop	Stop	Lost*	ms	Reset vector

* * Deep Software Standby: On-chip RAM contents are lost, but the 32-byte
 * Deep Standby Backup Register (DPSBKR) is retained. See rx72n_lpc_regs.h
 * for the DPSBKR accessor.
 *

8.87.1.2 Operating Power Control (OPCCR) Modes

Mode	ICLK max	Notes
High-speed (default)	240 MHz	Full performance
Low-speed 1	1 MHz	PLL/HOCO may be stopped
Low-speed 2	264 kHz	HOCO must be stopped (LOCO/Main only)

Note

RX72N only implements three OPCCR modes (high-speed, low-speed 1, low-speed 2). The "middle-speed" and "sub-oscillator-speed" modes from the RX100/RX200 family (SOPCCR) are not available on RX72N and therefore have no corresponding API enumerators in this driver.

8.87.1.3 Wake Source Selection (Deep Software Standby)

Wake sources for deep software standby are specified as a 32-bit bitmask passed to [rx_lpc_enter_deep_software_standby\(\)](#). The bitmask layout mirrors DPSIER0..DPSIER3 as a single little-endian word:

* bits [7: 0] - IRQ0-DS .. IRQ7-DS (DPSIER0)
 * bits [15: 8] - IRQ8-DS .. IRQ15-DS (DPSIER1)
 * bits [23:16] - LVD1/LVD2/RTC-P/RTC-A/NMI/IIC-SDA/IIC-SCL/USB (DPSIER2)
 * bits [31:24] - CAN1-RX (bit 24 only) (DPSIER3)
 *

The same encoding is returned by [rx_lpc_get_wake_flags\(\)](#) when reading the DPSIFRx flag registers after a deep-standby wake.

8.87.1.4 Hardware Register References

Register	Address	Manual Section	Purpose
SBYCR	0x0008000C	11.2.1 (p.405)	Standby control (SSBY, OPE)
OPCCR	0x000800A0	11.2.6 (p.414)	Operating power control

Register	Address	Manual Section	Purpose
RSTCKCR	0x000800A1	11.2.7 (p.417)	Sleep-mode return clock
DPSBYCR	0x0008C280	11.2.8 (p.418)	Deep standby control
DPSIER0-3	0x0008C282	11.2.9-12	Deep standby IRQ enable
DPSIFR0-3	0x0008C286	11.2.13-16	Deep standby wake flags
DPSIEGR0-3	0x0008C28A	11.2.17-20	Deep standby edge select
DPSBKR	0x0008C2A0	11.2.21 (p.433)	Deep standby backup RAM (32B)

8.87.1.5 Power Protection (PRCR)

All writes to SBYCR, OPCCR, RSTCKCR, and DPSBYCR require PRC1 to be unlocked via PRCR. This driver handles PRCR lock/unlock internally.

8.87.1.6 NASA Power of 10 Compliance

Rule	Status	Implementation
1	↔ [OK]↔	No goto/setjmp/recursion
2	↔ [OK]↔	All loops bounded (OPCMTSF poll has bounded retry)
3	↔ [OK]↔	Zero dynamic allocation
4	↔ [OK]↔	All functions < 60 lines
5	↔ [OK]↔	>= 2 pre/post conditions per function
6	↔ [OK]↔	Narrow scope, file-scope statics (s_*)
7	↔ [OK]↔	All return values checked
8	↔ [OK]↔	C23 typed enums, minimal preprocessor
9	↔ [OK]↔	Single-level pointers, no function pointers
10	↔ [OK]↔	Compiles with -Wall -Wextra -Werror

8.87.2 Enumeration Type Documentation

8.87.2.1 rx`lpc`deep`power`t

```
enum rx\_lpc\_deep\_power\_t : uint8_t
```

Deep-standby power supply configuration (DPSBYCR.DEEPCUT).

Selects how aggressively the deep-standby mode cuts power. Mirrors DPSBYCR.DEEPCUT[1:0] (RX72N Manual Section 11.2.8, page 418).

Note

The 10b DEEPCUT combination is reserved and is not exposed here.

Since

Version 1.0.0

Enumerator

<code>k_lpc_deep_ram_usb_on</code>	DEEPCUT=00b: standby RAM + USB powered
<code>k_lpc_deep_ram_usb_off</code>	DEEPCUT=01b: standby RAM + USB powered off

k_lpc_deep_lvd_off	DEEPCUT=11b: LVD also off (lowest power)
--------------------	--

Definition at line 152 of file [rx_lpc.h](#).

```
00152         : uint8_t {
00153     k_lpc_deep_ram_usb_on  = 0, /**< DEEPCUT=00b: standby RAM + USB powered */
00154     k_lpc_deep_ram_usb_off = 1, /**< DEEPCUT=01b: standby RAM + USB powered off */
00155     k_lpc_deep_lvd_off    = 2, /**< DEEPCUT=11b: LVD also off (lowest power) */
00156 } rx_lpc_deep_power_t;
```

8.87.2.2 rx_lpc_last_mode_t

```
enum rx_lpc_last_mode_t : uint8_t
```

Last low-power mode entered (test / diagnostic hook).

Recorded by rx_lpc_enter_*() prior to executing the WAIT instruction so that host-side unit tests can verify the driver reached the correct code path without executing a real WAIT.

Since

Version 1.0.0

Enumerator

k_lpc_mode_none	No low-power entry attempted yet
k_lpc_mode_sleep	Sleep mode (WAIT, SBYCR.SSBY=0)
k_lpc_mode_software_standby	Software standby (SBYCR.SSBY=1, DPSBY=0)
k_lpc_mode_deep_software_standby	Deep software standby (SSBY=1, DPSBY=1)

Definition at line 169 of file [rx_lpc.h](#).

```
00169         : uint8_t {
00170     k_lpc_mode_none      = 0, /**< No low-power entry attempted yet */
00171     k_lpc_mode_sleep     = 1, /**< Sleep mode (WAIT, SBYCR.SSBY=0) */
00172     k_lpc_mode_software_standby = 2, /**< Software standby (SBYCR.SSBY=1, DPSBY=0) */
00173     k_lpc_mode_deep_software_standby = 3, /**< Deep software standby (SSBY=1, DPSBY=1) */
00174 } rx_lpc_last_mode_t;
```

8.87.2.3 rx_lpc_opcc_mode_t

```
enum rx_lpc_opcc_mode_t : uint8_t
```

Operating Power Control (OPCCR) mode selector.

Selects the active-run power mode used while the CPU is running. The RX72N supports exactly three OPCCR modes (RX72N Manual Section 11.2.6, page 414). The underlying OPCM[2:0] field values are encoded directly.

Mode Transitions

Writing to OPCCR triggers an internal transition; the hardware sets OPCCR.OPCMTSF=1 until the transition completes. This driver polls that flag with a bounded retry count.

Warning

Low-speed mode 2 requires HOCO to be stopped. The caller is responsible for configuring the clock tree before invoking [rx_lpc_set_operating_power\(\)](#).

Since

Version 1.0.0

Enumerator

k_lpc_opcc_high_speed	High-speed mode (OPCM=000b, ICLK <= 240 MHz)
k_lpc_opcc_low_speed_1	Low-speed mode 1 (OPCM=110b, ICLK <= 1 MHz)
k_lpc_opcc_low_speed_2	Low-speed mode 2 (OPCM=111b, ICLK <= 264 kHz)

Definition at line 134 of file [rx_lpc.h](#).

```
00134         : uint8_t {
00135     k_lpc_opcc_high_speed = 0, /**< High-speed mode (OPCM=000b, ICLK <= 240 MHz) */
00136     k_lpc_opcc_low_speed_1 = 1, /**< Low-speed mode 1 (OPCM=110b, ICLK <= 1 MHz) */
00137     k_lpc_opcc_low_speed_2 = 2, /**< Low-speed mode 2 (OPCM=111b, ICLK <= 264 kHz) */
00138 } rx_lpc_opcc_mode_t;
```

8.87.2.4 rx`lpc`wake`flags``t`

```
enum rx\_lpc\_wake\_flags\_t : uint32_t
```

Wake-source bits for deep software standby.

32-bit bitmask layout used by [rx_lpc_enter_deep_software_standby\(\)](#) and returned by [rx_lpc_get_wake_flags\(\)](#). The layout mirrors DPSIER0..DPSIER3 (and the corresponding DPSIFR0..DPSIFR3 flag registers) as a single little-endian word.

Since

Version 1.0.0

Enumerator

k_lpc_wake_irq0	IRQ0-DS pin
k_lpc_wake_irq1	IRQ1-DS pin

```

8.87.3 Function Documentation

8.87.3.1 rx_lpc_enter_deep_software_standby()

```

rx_err_t rx_lpc_enter_deep_software_standby (
    uint32_t wake_mask,

```

```

    rx_lpc_deep_power_t deep_power,
    bool keep_io) [nodiscard]

```

Enter Deep Software Standby mode.

Configures DPSIER0..DPSIER3 from wake_mask, sets DPSBYCR.DEEPCUT, optionally sets DPSBYCR.IOKEEP, sets SBYCR.SSBY=1 and DPSBYCR.DPSBY=1 under PRC1 protection, then executes WAIT.

On deep-standby wake the MCU restarts from the reset vector. This function therefore does not return in that case on real hardware; the return path only exists for host-side unit tests. After reset, rx_lpc_was_deep_standby_wake() returns true and rx_lpc_get_wake_flags() reports which source caused the wake.

Parameters

in	wake_mask	Bitwise OR of rx_lpc_wake_flags_t values; must not be 0
in	deep_power	Deep-cut power configuration (DEEPCUT[1:0])
in	keep_io	If true, set DPSBYCR.IOKEEP=1 so I/O state is retained across the wake-up until the application clears it

Returns

rx_err_t Error code (returned only on host builds / on error)

Return values

k_rx_ok	Configuration accepted (host build)
k_rx_err_invalid_arg	wake_mask == 0 or contains undefined bits; deep_power not one of rx_lpc_deep_power_t
k_rx_err_not_initialized	rx_lpc_init() has not been called

Precondition

rx_lpc_init() has been called

wake_mask != 0 and (wake_mask & ~k_lpc_wake_all_mask) == 0

Corresponding pins / peripherals configured by the caller

Postcondition

DPSIER0..DPSIER3 reflect the enabled wake sources

DPSBYCR.DEEPCUT/IOKEEP/DPSBY configured per arguments

s_last_mode == k_lpc_mode_deep_software_standby (test-visible)

Warning

This function does not return on real hardware. Any cleanup required after deep standby must be performed at the reset vector / application startup path.

Since

Version 1.0.0

Definition at line 403 of file [rx_lpc.c](#).

```

00404 {
00405     if (s_initialized != k_lpc_initialized) {
00406         return k_rx_err_not_initialized;

Here is the call graph for this function:

8.87.3.2 rx_lpc_enter_sleep()

```
rx_err_t rx_lpc_enter_sleep (
    void ) [nodiscard]
```

Enter Sleep mode (CPU stop, peripherals run).

Clears SBYCR.SSBY under PRC1 protection, then executes the WAIT instruction. On RX72N, WAIT with SSBY=0 enters sleep mode. Execution resumes from the instruction after WAIT when any unmasked interrupt fires.

Returns

rx_err_t Error code

Return values

k_rx_ok	Returned from sleep by an interrupt
k_rx_err_not_initialized	rx_lpc_init() has not been called

Precondition

[rx_lpc_init\(\)](#) has been called

At least one interrupt source is armed and enabled in ICU

Postcondition

SBYCR.SSBY == 0 on exit

s_last_mode == k_lpc_mode_sleep (test-visible)

Note

On host builds the WAIT instruction is replaced by a no-op.

Since

Version 1.0.0

Enter Sleep mode (CPU stop, peripherals run).

Configures SBYCR for Sleep mode (SSBY=0) under PRCR.PRC1 protection, then issues a WAIT instruction to halt the CPU. Peripheral clocks continue running, so any enabled interrupt resumes execution at the instruction following WAIT. Records the last entered mode for post-mortem diagnostics. On the unit-test target the WAIT is skipped.

Note

Not thread-safe. Serialize all rx_lpc_* operations.

Definition at line 338 of file [rx_lpc.c](#).

```
00339 {
00340     if (s_initialized != k_lpc_initialized) {

Here is the call graph for this function:

8.87.3.3 rx_lpc_enter_software_standby()

```
rx_err_t rx_lpc_enter_software_standby (
    void ) [nodiscard]
```

Enter Software Standby mode.

Sets SBYCR.SSBY=1 and clears DPSBYCR.DPSBY=0 under PRC1 protection, then executes WAIT. On exit the MCU resumes at the instruction after WAIT (not the reset vector). RAM contents are retained.

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Returned from software standby
<code>k_rx_err_not_initialized</code>	rx_lpc_init() has not been called

Precondition

[rx_lpc_init\(\)](#) has been called

A wake source (NMI, IRQn, RTC, IWDG, LVD) is enabled in the ICU

Postcondition

SBYCR.SSBY == 1 on entry, hardware auto-clears on wake

`s_last_mode` == `k_lpc_mode_software_standby` (test-visible)

Note

Typical current draw ~3 uA at 3.3 V (RX72N datasheet Table 58.xx).

Since

Version 1.0.0

Enter Software Standby mode.

Configures SBYCR.SSBY=1 and DPSBYCR.DPSBY=0 under PRCR.PRC1 so that the upcoming WAIT instruction enters Software Standby (not Sleep, not Deep Standby). Most peripheral clocks are gated off; only configured wake sources (level-sensitive IRQ pins, RTC, watchdog) can resume execution. On the unit-test target the WAIT is skipped.

Note

Not thread-safe. Serialize all `rx_lpc_*` operations.

Definition at line 374 of file [rx_lpc.c](#).

```

00375 {
00376     if (s_initialized != k_lpc_initialized) {
00377         return k_rx_err_not_initialized;
00378     }
00379 }
00380 #ifdef __RX__

Here is the call graph for this function:

8.87.3.4 rx_lpc_get_wake_flags()

```

rx_err_t rx_lpc_get_wake_flags (
    uint32_t * flags) [nodiscard]

```

Read the deep-standby wake flags (DPSIFR0..DPSIFR3).

Returns a 32-bit bitmask describing which wake sources triggered the most recent deep-standby exit. The layout matches [rx_lpc_wake_flags_t](#). Reading does not clear the flags; the driver clears them in [rx_lpc_init\(\)](#).

Parameters

out	flags	Pointer to receive the wake-flag bitmask
-----	-------	--

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Flags read successfully
<code>k_rx_err_invalid_arg</code>	flags is NULL
<code>k_rx_err_not_initialized</code>	rx_lpc_init() has not been called

Precondition

[rx_lpc_init\(\)](#) has been called
 flags != NULL

Postcondition

*flags contains a bitwise OR of [rx_lpc_wake_flags_t](#) values

Since

Version 1.0.0

Read the deep-standby wake flags (DPSIFR0..DPSIFR3).

Copies the cached `s_latched_wake_flags` into the caller-supplied destination. The bitfield has one bit per wake source; the layout is defined by `rx_lpc_wake_t`. Useful after wake to determine which event resumed execution.

Note

Not safe from ISR (acquires no lock but reads driver state that could be torn during init).

Definition at line 503 of file [rx_lpc.c](#).

```
00504 {
00505     if (flags == NULL) {
00506         return k_rx_err_invalid_arg;
00507     }
00508     if (s_initialized != k_lpc_initialized) {
00509         return k_rx_err_not_initialized;
00510     }
00511
00512     *flags = s_latched_wake_flags;
00513     return k_rx_ok;
00514 }
```

References [k_lpc_initialized](#), [s_initialized](#), and [s_latched_wake_flags](#).

8.87.3.5 rx`lpc`init()

```
rx_err_t rx_lpc_init (
    void ) [nodiscard]
```

Initialize the Low Power Consumption driver.

Clears the driver's internal state, latches whether the most recent reset was a deep-standby wake-up (so application code can read it back via [rx_lpc_was_deep_standby_wake\(\)](#)), and pre-clears any pending deep-standby wake flags (DPSIFR0..DPSIFR3) that may have been set by the preceding deep-standby exit.

This function does not change the operating power mode; applications should call [rx_lpc_set_operating_power\(\)](#) separately if they want to switch away from the default high-speed mode.

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Driver initialized successfully
----------------------	---------------------------------

Precondition

May be called exactly once per reset
System clocks must already be configured

Postcondition

Driver state tracking is reset
Deep-standby wake flags are cleared

Note

Safe to call from single-threaded startup only.

Since

Version 1.0.0

Definition at line 242 of file [rx_lpc.c](#).

```

00243 {
00244     /* Latch whatever the boot path told us about the previous reset */

Here is the call graph for this function:

8.87.3.6 rx`lpc`set`operating`power()

```
rx_err_t rx_lpc_set_operating_power (
    rx_lpc_opcc_mode_t mode) [nodiscard]
```

Select the operating power control (OPCCR) mode.

Writes OPCCR.OPCM[2:0] under PRC1 protection and polls OPCCR.OPCMTSF=0 for transition completion (bounded retry).

Parameters

in	mode	Target operating power mode
----	------	-----------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Mode transition completed
k_rx_err_invalid_arg	mode not one of rx_lpc_opcc_mode_t
k_rx_err_not_initialized	rx_lpc_init() has not been called
k_rx_err_hw_timeout	OPCMTSF did not clear within bounded retries

Precondition

[rx_lpc_init\(\)](#) has been called

Clock tree pre-conditions for the target mode are satisfied by the caller

Postcondition

OPCCR.OPCM[2:0] reflects the requested mode

OPCCR.OPCMTSF == 0

Warning

Low-speed mode 2 requires the caller to stop HOCO first (RX72N Manual Section 11.4.4). Low-speed mode 1 requires PLL to be stopped.

Since

Version 1.0.0

Select the operating power control (OPCCR) mode.

Programs the OPCCR register with the OPCM bits derived from the requested mode (high-speed / middle-speed / low-power, etc.). Performs the standard PRCR.PRC1 unlock-write-lock dance, then bounded-polls the OPCMTSF transition-status flag for completion (max k_opcmtsfs_poll_max iterations). On the unit-test target the register write is skipped.

Note

Not thread-safe. Serialize all `rx_lpc_*` operations.

Definition at line 293 of file `rx_lpc.c`.

```

00294 {
00295     if (s_initialized != k_lpc_initialized) {
00296         return k_rx_err_not_initialized;
00297     }
00298

Here is the call graph for this function:

8.87.3.7 rx_lpc_was_deep_standby_wake()

```

bool rx_lpc_was_deep_standby_wake (
    void ) [nodiscard]

```

Query whether the last reset was caused by a deep-standby wake.

The information is latched by `rx_lpc_init()` from the internal state it inherits from the reset path. On real hardware the caller is expected to have inspected `RSTSR0/1/2` (see `rx_rstsr` accessors) and, if appropriate, to have called the test-only setter `rx_lpc_test_set_deep_standby_wake()` or equivalent boot-path bridge. The default for a cold power-on is false.

Returns

true if the most recent reset was a deep-standby wake-up
false otherwise

Precondition

[rx_lpc_init\(\)](#) has been called

Postcondition

Return value is stable until the next reset

Since

Version 1.0.0

Query whether the last reset was caused by a deep-standby wake.

Returns the cached `s_was_deep_standby_wake` flag latched at boot time. Allows application code to distinguish between a power-on reset and a resume from Deep Software Standby and take different paths (e.g., skip full re-initialization when waking).

Returns

true if the most recent reset was a Deep Software Standby wake; false otherwise (or before [rx_lpc_init\(\)](#) ran).

Precondition

None (function is safe to call at any time after init or before).

Postcondition

No state mutated.

Return value is stable across multiple calls in the same boot session.

Note

Safe from any context including ISR; pure read of static storage.

00001 /**
00002  * @file rx_lpc.h
00003  * @brief Low Power Consumption (LPC) HAL Driver for RX72N
00004  *
00005  * @details
00006  * **Hardware Abstraction Layer** for the RX72N Low Power Consumption subsystem.
00007  * Provides a small, auditable API for entering the three RX72N low-power modes
00008  * and for selecting the operating power control mode that governs active-run
00009  * current.
00010  *
00011  * ## Supported Modes (RX72N Manual Chapter 11)
00012  *
00013  * | Mode | CPU | Peripherals | RAM | Wake Latency | Exit Vector |
00014  * |-----|-----|-----|-----|-----|-----|
00015  * | Sleep | Stop | Run | Retained | ns | Continue next PC |
00016  * | Software Standby | Stop | Stop | Retained | us | Continue next PC |
00017  * | Deep Software Standby | Stop | Stop | Lost* | ms | Reset vector |
00018  *
00019  * @verbatim
00020  * * Deep Software Standby: On-chip RAM contents are lost, but the 32-byte
00021  * * Deep Standby Backup Register (DPSBKR) is retained. See rx72n_lpc_regs.h
00022  * * for the DPSBKR accessor.
00023  * @endverbatim
00024  *
00025  * ## Operating Power Control (OPCCR) Modes
00026  *
00027  * | Mode | ICLK max | Notes |
00028  * |-----|-----|-----|
00029  * | High-speed (default) | 240 MHz | Full performance |
00030  * | Low-speed 1 | 1 MHz | PLL/HOCO may be stopped |
00031  * | Low-speed 2 | 264 kHz | HOCO must be stopped (LOCO/Main only) |
00032  *
00033  * @note RX72N only implements three OPCCR modes (high-speed, low-speed 1,
00034  * low-speed 2). The "middle-speed" and "sub-oscillator-speed" modes
00035  * from the RX100/RX200 family (SOPCCR) are **not available** on RX72N
00036  * and therefore have no corresponding API enumerators in this driver.
00037  *
00038  * ## Wake Source Selection (Deep Software Standby)
00039  *
00040  * * Wake sources for deep software standby are specified as a 32-bit bitmask
00041  * * passed to rx_lpc_enter_deep_software_standby(). The bitmask layout mirrors
00042  * * DPSIER0..DPSIER3 as a single little-endian word:
00043  *
00044  * @verbatim
00045  * * bits [ 7: 0] - IRQ0-DS .. IRQ7-DS (DPSIER0)
00046  * * bits [15: 8] - IRQ8-DS .. IRQ15-DS (DPSIER1)
00047  * * bits [23:16] - LVD1/LVD2/RTC-P/RTC-A/NMI/IIC-SDA/IIC-SCL/USB (DPSIER2)
00048  * * bits [31:24] - CAN1-RX (bit 24 only) (DPSIER3)
00049  * @endverbatim
00050  *
00051  * * The same encoding is returned by rx_lpc_get_wake_flags() when reading the
00052  * * DPSIFRx flag registers after a deep-standby wake.
00053  *
00054  * ## Hardware Register References
00055  *
00056  * | Register | Address | Manual Section | Purpose |
00057  * |-----|-----|-----|-----|
00058  * | SBYCR | 0x0008000C | 11.2.1 (p.405) | Standby control (SSBY, OPE) |
00059  * | OPCCR | 0x000800A0 | 11.2.6 (p.414) | Operating power control |
00060  * | RSTCKCR | 0x000800A1 | 11.2.7 (p.417) | Sleep-mode return clock |
00061  * | DPSBYCR | 0x0008C280 | 11.2.8 (p.418) | Deep standby control |
00062  * | DPSIER0-3 | 0x0008C282 | 11.2.9-12 | Deep standby IRQ enable |
00063  * | DPSIFR0-3 | 0x0008C286 | 11.2.13-16 | Deep standby wake flags |
00064  * | DPSIEGR0-3 | 0x0008C28A | 11.2.17-20 | Deep standby edge select |
00065  * | DPSBKR | 0x0008C2A0 | 11.2.21 (p.433) | Deep standby backup RAM (32B) |
00066  *
00067  * ## Power Protection (PRCR)
00068  *
00069  * * All writes to SBYCR, OPCCR, RSTCKCR, and DPSBYCR require PRC1 to be
00070  * * unlocked via PRCR. This driver handles PRCR lock/unlock internally.
00071  *

Peripheral Select (PSEL) codes for common STAR project functions.

Functions

- `rx_err_t rx_mpc_set_gpio` (`rx_port_pin_t pin`)
Configure pin for GPIO (General Purpose I/O) function.
- `rx_err_t rx_mpc_set_peripheral` (`const rx_mpc_peripheral_config_t *config`)
Configure pin for peripheral function with specified PSEL code.
- `rx_err_t rx_mpc_set_mtu_pwm` (`rx_port_pin_t pin`)
Configure pin for MTU3a timer PWM output (MTIOC).
- `rx_err_t rx_mpc_set_mtu_encoder` (`rx_port_pin_t pin`)
Configure pin for MTU3a encoder/phase counter input (MTCLK).
- `rx_err_t rx_mpc_set_tpu_encoder` (`rx_port_pin_t pin`)
Configure pin for TPU encoder/phase counter input (TCLK).
- `rx_err_t rx_mpc_set_adc` (`rx_port_pin_t pin`)
Configure pin for ADC analog input.
- `rx_err_t rx_mpc_set_sci` (`rx_port_pin_t pin`)
Configure pin for SCI (Serial Communication Interface) UART function.
- `rx_err_t rx_mpc_set_riic` (`rx_port_pin_t pin`)
Configure pin for RIIC (I2C) bus function.
- `rx_err_t rx_mpc_set_rspi` (`rx_port_pin_t pin`)
Configure pin for RSPI (SPI) bus function.
- `rx_err_t rx_mpc_set_gptw` (`rx_port_pin_t pin`)
Configure pin for GPTW (General PWM Timer) complementary output.
- `rx_err_t rx_mpc_set_usb_vbus` (`rx_port_pin_t pin`)
Configure pin for USB VBUS detection function.
- `rx_err_t rx_mpc_set_irq` (`rx_port_pin_t pin`)
Configure pin for IRQ (external interrupt) function.

8.89.1 Detailed Description

Multi-Function Pin Controller (MPC) Driver API for RX72N.

High-level driver for configuring RX72N GPIO pin multiplexing. The MPC module controls which peripheral function is connected to each physical pin through Pin Function Select (PFS) registers.

System Architecture

```

* | Note: rx_mpc_set_irq() and rx_mpc_set_adc() bypass          |
* | rx_mpc_set_peripheral() and write ISEL/ASEL bits directly  |

Pin Configuration Flow

Pin Assignments

Application-level pin assignments are defined in `hardware_config.h`. This driver provides the MPC register interface for any valid pin/PSEL combination. See the RX72N Hardware Manual pin function tables for valid (pin, PSEL) pairs.

See also

`hardware_config.h` Application-level pin assignments

Hardware Requirements

Resource	Requirement	Notes
MPC Base	0x0008C100	Fixed hardware address
PCLKB	Active	Required for register access
MSTPCRA	Bit 9 = 0	MPC module stop cleared

Performance Characteristics

Operation	Typical Time	Notes
Pin config	~1 us	PWPR unlock/lock overhead
Bulk config (10 pins)	~10 us	Sequential calls

Memory Usage

Category	Size	Notes
Code	~800 bytes	All functions
Static data	4 bytes	Tag string only
Stack (per call)	16 bytes	Local variables

Thread Safety

Not thread-safe. The MPC PWPR unlock/lock sequence is non-atomic. If multiple threads call MPC functions concurrently, race conditions can occur where one thread's unlock is clobbered by another's lock. Use external mutex protection or configure all pins during single-threaded initialization before starting RTOS.

Initialization Order

MPC configuration should occur early in system initialization:

1. Clock configuration (PCLKB must be running)
2. Module stop clear (if MPC in module stop)
3. MPC pin configuration < This module
4. GPIO direction configuration (PMR, PDR registers)
5. Peripheral driver initialization

Usage Example

```

#include "rx_mpc.h"
#include "rx_port_constants.h"

void hardware_init_pins(void)
{
    rx_err_t err;

    // Configure motor PWM pins (GPTW channel 0)
    const rx_mpc_peripheral_config_t pwm_config = {
        .pin = k_port_e_pin_5, // PE5 = GPTW0A
        .psel = k_psel_gptw // GPTW function (0x1E)
    };
    err = rx_mpc_set_peripheral(&pwm_config);
    if (err != k_rx_ok) {
        // Handle error
    }

    // Configure encoder pins (MTU phase counting)
    err = rx_mpc_set_mtu_encoder(k_port_2_pin_4); // P24 = MTCLKA
    err = rx_mpc_set_mtu_encoder(k_port_2_pin_5); // P25 = MTCLKB

    // Configure debug UART (SCI9)
    err = rx_mpc_set_sci(k_port_b_pin_7); // PB7 = TXD9
    err = rx_mpc_set_sci(k_port_b_pin_6); // PB6 = RXD9

    // Configure SPI communication (RSPI0)
    err = rx_mpc_set_rspi(k_port_a_pin_0); // PA0 = COPI
    err = rx_mpc_set_rspi(k_port_a_pin_1); // PA1 = CIPO
    err = rx_mpc_set_rspi(k_port_a_pin_3); // PA3 = CLK
    err = rx_mpc_set_rspi(k_port_a_pin_4); // PA4 = SSL0
}

```

Error Handling Example

```

rx_err_t configure_pin_safe(rx_port_pin_t pin, uint8_t psel)
{
    // Validate PSEL range before calling
    if (psel > 0x1F) {
        rx_log_error("MPC", "PSEL exceeds 5-bit maximum");
        return k_rx_err_invalid_arg;
    }

    rx_mpc_peripheral_config_t config = {
        .pin = pin,
        .psel = psel
    };

    rx_err_t err = rx_mpc_set_peripheral(&config);
    if (err != k_rx_ok) {
        rx_log_error("MPC", "Pin configuration failed");
        // Configuration failed - pin remains in previous state
        return err;
    }

    // Remember: Also need to set PMR bit to enable peripheral mode!
    return k_rx_ok;
}

```

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, longjmp, or recursion
- Rule 2: [OK] All loops have fixed upper bounds (switch/case only)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] All functions < 60 lines
- Rule 5: [OK] Minimum 2 assertions per function (parameter validation)
- Rule 6: [OK] Variables declared at smallest scope
- Rule 7: [OK] All return values checked
- Rule 8: [OK] C23 typed enums for all constants, no magic numbers
- Rule 9: [WARN] Function pointers not used (simple direct calls)
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

SOLID Principles

- Single Responsibility: MPC driver handles only pin mux configuration
- Open/Closed: New peripherals added via [rx_mpc_set_peripheral\(\)](#) without modifying existing code
- Interface Segregation: Convenience functions (`set_sci`, `set_rspi`) separate from low-level `set_peripheral()`
- Dependency Inversion: Higher-level drivers depend on this abstraction, not on raw register writes

Module Dependencies

8.89.2 Data Structure Documentation

8.89.2.1 struct rx_mpc_peripheral_config_t

MPC peripheral configuration structure for pin function assignment.

This structure groups related parameters to prevent accidental parameter swapping when calling `rx_mpc_set_peripheral()`. Using a struct provides:

- Type safety (compiler catches wrong parameter types)
- Named parameters (self-documenting code)
- Extensibility (can add fields without changing function signature)

Memory Layout

Offset	Size	Field	Type	Alignment
0	2	pin	rx_port_pin_t (uint16_t)	2
2	1	psel	uint8_t	1
3	1	(padding)	-	-
Total	4 bytes			

Field Relationships

- `pin` determines which PFS register to modify
- `psel` determines what value to write to that register
- The (pin, psel) pair must be valid per RX72N hardware manual appendix

Usage Example - Basic Configuration

```
// Configure PE5 for GPTW0A (motor PWM output)
rx_mpc_peripheral_config_t pwm_config = {
    .pin = k_port_e_pin_5, // PE5
    .psel = k_psel_gptw    // GPTW function select (0x1E)
};
rx_err_t err = rx_mpc_set_peripheral(&pwm_config);
```

Usage Example - Multiple Pins

```
// Configure all SPI pins using array
const rx_mpc_peripheral_config_t spi_pins[] = {
    { .pin = k_port_a_pin_0, .psel = 0x0D }, // COPI
    { .pin = k_port_a_pin_1, .psel = 0x0D }, // CIP0
    { .pin = k_port_a_pin_3, .psel = 0x0D }, // CLK
    { .pin = k_port_a_pin_4, .psel = 0x0D }, // SSL0
};

for (uint8_t i = 0; i < 4; i++) {
    rx_err_t err = rx_mpc_set_peripheral(&spi_pins[i]);
    if (err != k_rx_ok) {
        // Handle error
    }
}
```

Invariant

pin must be a valid rx_port_pin_t value from rx_port_constants.h

psel must be in range [0, 31] (5-bit field)

(pin, psel) combination must be valid per hardware manual

Collaboration diagram for rx_mpc_peripheral_config_t:

Data Fields

rx_port_pin_t	pin	GPIO pin to configure for peripheral function. Encoded pin identifier from rx_port_constants.h combining port and pin number. Use the k_port_X_pin_Y constants for type safety. Valid Values Any valid rx_port_pin_t constant, e.g.: • k_port_a_pin_0 through k_port_a_pin_7 • k_port_b_pin_0 through k_port_b_pin_7 • k_port_e_pin_0 through k_port_e_pin_7 • etc. Note On 144-pin package, ports G, H are not available Warning Using invalid pin values returns k_rx_err_invalid_arg																											
uint8_t	psel	Peripheral function select code (PSEL field value). Value written to the PSEL[4:0] field of the PFS register. This determines which peripheral function the pin is connected to. Valid Range: [0, 31 (0x00 - 0x1F)] <table border="1"> <thead> <tr> <th>PSEL</th><th>Function</th><th>Typical Pins</th></tr> </thead> <tbody> <tr> <td>0x00</td><td>Hi-Z/GPIO</td><td>All</td></tr> <tr> <td>0x01</td><td>MTU I/O compare (MTIOC)</td><td>P14-P17, P24-P27</td></tr> <tr> <td>0x02</td><td>MTU clock input (MTCLK)</td><td>P24, P25, PC0, PC1</td></tr> <tr> <td>0x03</td><td>MTU phase counter</td><td>P24, P25</td></tr> <tr> <td>0x1E</td><td>GPTW output (GTIOC)</td><td>PE3, PE7, P23, P22, etc.</td></tr> <tr> <td>0x0A</td><td>SCI (TXD/RXD)</td><td>PB6, PB7</td></tr> <tr> <td>0x0D</td><td>RSPI (CLK/COPI/CIPO/↔SSL)</td><td>PA0-PA4</td></tr> <tr> <td>0x0F</td><td>RIIC (SCL/SDA)</td><td>P12, P13</td></tr> </tbody> </table> Common Values (varies by pin, check hardware manual): Warning Wrong PSEL value for a pin may cause hardware malfunction See also rx_pin_psel_t Predefined PSEL constants	PSEL	Function	Typical Pins	0x00	Hi-Z/GPIO	All	0x01	MTU I/O compare (MTIOC)	P14-P17, P24-P27	0x02	MTU clock input (MTCLK)	P24, P25, PC0, PC1	0x03	MTU phase counter	P24, P25	0x1E	GPTW output (GTIOC)	PE3, PE7, P23, P22, etc.	0x0A	SCI (TXD/RXD)	PB6, PB7	0x0D	RSPI (CLK/COPI/CIPO/↔SSL)	PA0-PA4	0x0F	RIIC (SCL/SDA)	P12, P13

8.89.3 Enumeration Type Documentation

8.89.3.1 rx_pin_function_t

enum [rx_pin_function_t](#) : uint8_t

High-level pin function mode selection.

Specifies whether a pin is configured for GPIO operation or peripheral function mode. This is a conceptual abstraction - the actual hardware configuration is done through PFS register PSEL field and PORT PMR bit.

Pin Configuration State Machine

Note

This enum is for documentation/API clarity. Actual hardware uses PSEL field values directly.

See also

[rx_mpc_set_gpio\(\)](#) Configure pin for GPIO mode

[rx_mpc_set_peripheral\(\)](#) Configure pin for peripheral mode

Since

Version 1.0.0

Enumerator

k_pin_function_gpio	GPIO mode - pin controlled by PORT registers. Pin is disconnected from all peripheral functions. Direction and data controlled by PORT PDR and PODR registers. This is the power-on default for all pins. PFS Register Value: 0x00 (PSEL=0, ISEL=0, ASEL=0)
k_pin_function_periph	Peripheral function mode - pin connected to peripheral. Pin is connected to a peripheral function as determined by the PSEL field. The PORT PMR bit must also be set to 1 to actually enable peripheral mode. PFS Register Value: PSEL field set to peripheral code Note This is a placeholder value; actual PSEL varies by function

Definition at line 382 of file [rx_mpc.h](#).

```

00382         : uint8_t {
00383     /**
00384     * @brief GPIO mode - pin controlled by PORT registers
00385     * @details
00386     * Pin is disconnected from all peripheral functions. Direction and
00387     * data controlled by PORT PDR and PODR registers. This is the
00388     * power-on default for all pins.
00389     * @par PFS Register Value: 0x00 (PSEL=0, ISEL=0, ASEL=0)
00390     */
00391     k_pin_function_gpio = 0x00,
00392
00393     /**

00398     * enable peripheral mode.
00399     * @par PFS Register Value: PSEL field set to peripheral code
00400     * @note This is a placeholder value; actual PSEL varies by function
00401     */
00402     k_pin_function_periph = 0x01,
00403 } rx_pin_function_t;

```

8.89.3.2 rx_pin_psel_t

```
enum rx_pin_psel_t : uint8_t
```

Peripheral Select (PSEL) codes for common STAR project functions.

These values are written to the PSEL[4:0] field of PFS registers to select which peripheral function a pin is connected to. Values are pin-specific - these constants represent the most common values used in the STAR project.

PSEL Field in PFS Register

```

* Bit:  7    6    5    4 3 2 1 0
*      +-----+-----+-----+-----+
*      | ASEL | ISEL | Rsvd |  PSEL[4:0]  |
*      +-----+-----+-----+-----+
*                               <-- These values -->
*

```

PSEL Values by Peripheral (STAR Project)

Peripheral	PSEL	Pins Used	Function
MTU3a MTIOC	0x01	P14-P17, P24-P27	PWM output
MTU3a MTCLK	0x02	P24, P25, PC0, PC1	Clock/encoder input
MTU3a Phase	0x03	P24, P25	Phase counting mode
GPTW GTIOC	0x1E	PE3, PE7, P23, P22, etc.	PWM output
SCI TXD/RXD	0x0A	PB6, PB7	UART data
RSPI signals	0x0D	PA0-PA4	SPI bus
RIIC SDA/SCL	0x0F	P12, P13	I2C bus

Warning

PSEL values are pin-specific! A value that works for one pin may select a completely different function on another pin. Always verify against the RX72N Hardware Manual pin function tables.

Usage Example

```

// Configure PB7 for SCI9 TXD
rx_mpc_peripheral_config_t config = {
    .pin = k_port_b_pin_7,
    .psel = k_psel_sci_tx // 0x0A
};
rx_mpc_set_peripheral(&config);

```

RX72N Hardware Manual, Appendix for complete pin function tables

Since

Version 1.0.0

Enumerator

k_psel_mtu_ioc	MTU I/O Compare/PWM output (MTIOC). Connects pin to MTU3a compare match output for PWM generation. Typical Pins: P14-P17 (MTU3), P24-P27 (MTU4) Application: Motor PWM outputs when using MTU3a timer
k_psel_mtu_clk	MTU clock input (MTCLKA/B/C/D). Connects pin to MTU3a external clock input. On RX72N, PSEL = 0x02 (0b000010) is the generic "MTCLK" function and is the same value whether the MTU is configured for normal external-clock counting or for phase counting (quadrature encoder) mode. The counting mode is selected by MTU.TMDR, not by PSEL – callers must not pick a different PSEL just because they want phase counting. Reference: RX72N Group Hardware Manual (R01UH0824EJ0111), chapter 23 "Multi-Function Pin Controller (MPC)". For the 144-pin LFQFP package: • Table 23.5 (P1x pins): row PSEL = 000010b -> MTCLKA on P14, MTCLKB on P15 • Table 23.6 (P2x pins): row PSEL = 000010b -> MTCLKC on P22, MTCLKD on P23, MTCLKA on P24, MTCLKB on P25 • Table 23.17 (PAx pins): row PSEL = 000010b -> MTCLKC on PA1, MTCLKD on PA3, MTCLKA on PA4, MTCLKB on PA6 • Table 23.19 (PCx pins): row PSEL = 000010b -> MTCLKC on PC4, MTCLKD on PC5, MTCLKA on PC6, MTCLKB on PC7 Every MTCLK pin on this package resolves to PSEL = 0b00'0010 = 0x02. Typical Pins: P24/P25 (MTCLKA/B), PA1/PC5 (MTCLKC/D) Application: Encoder pulse counting, quadrature phase counting

k_psel_mtu_phase	MTU encoder phase counting input (alias for k_psel_mtu_clk). Same PSEL value on RX72N as k_psel_mtu_clk – both MTU external clock counting and MTU phase counting route through PSEL=0x02, and the distinction is selected later via MTU.TMDR (phase counting mode bits). The split constants exist only so calling code reads clearly; do not assume they are different values. Typical Pins: P24/P25 pair, PA1/PC5 pair (same as k_psel_mtu_clk) Application: Quadrature encoder interface with direction detection Note Previously 0x03 – that was wrong and caused MTU encoders to stay at TCNT=0x0000 because PSEL=0x03 on MTU-candidate pins selects an unrelated function (TPU on Port C pins, or nothing elsewhere). See chapter 23 of the RX72N Group Hardware Manual (R01UH0824EJ0111), Tables 23.5, 23.6, 23.17, 23.19.
k_psel_tpu_clk_portc	TPU external clock input on Port C pins (TCLKA/B/C/D on PC0-PC3). RX72N assigns TPU external clock to alternate function PSEL=0x03 on Port C pins only. Non-Port-C candidates for the same TCLK signal use a different PSEL (see k_psel_tpu_clk_alt). Reference: RX72N Group Hardware Manual (R01UH0824EJ0111), chapter 23 "Multi-Function Pin Controller (MPC)", Table 23.19 (PCx pins). For the 144-pin LFQFP package the row PSEL = 000011b maps to: PC0 -> TCLKC, PC1 -> TCLKD, PC2 -> TCLKA, PC3 -> TCLKB All four TPU TCLK inputs on Port C resolve to PSEL = 0b00'0011 = 0x03. Typical Pins: PC2 (TCLKA), PC3 (TCLKB), PC0 (TCLKC), PC1 (TCLKD) Application: Rear-wheel quadrature encoder Phase A inputs on Port C Note rx_mpc_set_tpu_encoder() picks between this and k_psel_tpu_clk_alt automatically based on the port number of the pin argument.

k_psel_tpu_clk_alt	TPU external clock input on non-Port-C pins (TCLKA/B/C/D). RX72N assigns TPU external clock to alternate function PSEL=0x04 on Port 1, Port A, and Port B candidates for the TCLK signals. This differs from the Port C candidates (k_psel_tpu_clk_portc = 0x03) and the difference is silicon-level – the same TCLK signal is routed through different PFS alternate-function slots on different ports. Reference: RX72N Group Hardware Manual (R01UH0824EJ0111), chapter 23 "Multi-Function Pin Controller (MPC)". For the 144-pin LFQFP package the row PSEL = 000100b maps to: • Table 23.5 (P1x pins): P14 -> TCLKA, P15 -> TCLKB, P16 -> TCLKC, P17 -> TCLKD • Table 23.17 (PAx pins): PA3 -> TCLKB • Table 23.18 (PBx pins): PB2 -> TCLKC, PB3 -> TCLKD All non-Port-C TPU TCLK inputs resolve to PSEL = 0b00'0100 = 0x04. Typical Pins: PA3 (TCLKB), PB3 (TCLKD) – STAR rear-wheel Phase B Application: Rear-wheel quadrature encoder Phase B inputs Note Before this split, rx_mpc_set_tpu_encoder() used PSEL=0x03 for every TPU pin, which silently misconfigured PA3/PB3 (the two non-Port-C pins on rear wheels) so one half of each rear-wheel encoder never incremented.
k_psel_sci_tx	SCI transmit data output (TXD). Connects pin to SCI channel transmit data output. Typical Pins: PB7 (SCI9-TXD for debug UART) Application: UART transmit, debug console output Note Same PSEL value used for both TX and RX on SCI pins

k_psel_sci_rx	SCI receive data input (RXD). Connects pin to SCI channel receive data input. Typical Pins: PB6 (SCI9-RXD for debug UART) Application: UART receive, debug console input Note Same PSEL value as TX (pin determines actual function)
k_psel_riic_scl	RIIC clock line (SCL). Connects pin to RIIC (I2C) clock line with open-drain output. Typical Pins: P12 (RIIC0-SCL) Application: I2C bus clock for sensors/peripherals Note RIIC automatically configures open-drain when enabled
k_psel_riic_sda	RIIC data line (SDA). Connects pin to RIIC (I2C) data line with open-drain output. Typical Pins: P13 (RIIC0-SDA) Application: I2C bus data for sensors/peripherals Note Same PSEL value as SCL (pin determines actual function)
k_psel_rspi_clk	RSPI clock (RSPCK). Connects pin to RSPI serial clock output (controller mode) or input (peripheral mode). Typical Pins: PA5 (RSPI0-RSPCKA); see RX72N HW manual R01UH0824EJ0111 Ch 23 Application: SPI bus clock for RPi5 communication

k_psel_rspi_copi	RSPI Controller Out Peripheral In (COPI, formerly MOSI). Connects pin to RSPI data output line in controller mode. Typical Pins: PA6 (RSPI0-MOSIA / COPI); see RX72N HW manual R01UH0824EJ0111 0 Application: SPI transmit data to peripherals Note Uses OSHWA-approved inclusive terminology
k_psel_rspi_cipo	RSPI Controller In Peripheral Out (CIPO, formerly MISO). Connects pin to RSPI data input line in controller mode. Typical Pins: PA7 (RSPI0-MISOA / CIPO); see RX72N HW manual R01UH0824EJ0111 0 Application: SPI receive data from peripherals Note Uses OSHWA-approved inclusive terminology
k_psel_adc	ADC analog input mode. Disables digital input buffer for analog signal measurement. Actually sets ASEL bit in PFS, not PSEL field. Typical Pins: P40-P47 (AN000-AN007) Application: Motor current sensing, analog input measurement Note Use rx_mpc_set_adc() for proper configuration (sets ASEL bit)

k_psel_usb_vbus	USB VBUS detection input. Connects pin to USB VBUS detection for 5V presence sensing. Required for USB enumeration and power monitoring. Typical Pins: P1.6 (USB0_VBUS on RX72N) Application: USB CDC debug interface, RPi5 communication Note Active-high: pin reads 1 when 5V present on USB bus Requires additional USB PHY and controller configuration Since Version 1.0.0
k_psel_gptw	GPTW complementary PWM output (GTIOC). Connects pin to GPTW (General PWM Timer) complementary PWM output with dead-time insertion for motor control. GPTW provides 4 channels (GPTW0-GPTW3) with phase-staggered PWM outputs. Typical Pins: • P2.3, P1.7 (GPTW0 - Motor 0 IN2/IN1) • P2.2, PC.3 (GPTW1 - Motor 1 IN2/IN1) • PE.3, P8.6 (GPTW2 - Motor 2 IN2/IN1) • PE.7, PC.6 (GPTW3 - Motor 3 IN2/IN1) Application: Motor control with direction/PWM signals for DRV8263H Feature: 90-degree phase staggering reduces peak current draw Since Version 1.0.0

8.89.4 Function Documentation

8.89.4.1 rx_mpc_set_adc()

```

rx_err_t rx_mpc_set_adc (
    const rx_port_pin_t pin) [nodiscard]

```

Configure pin for ADC analog input.

Configures a pin for analog-to-digital converter input by setting the ASEL bit in the PFS register. This disables the digital input buffer to prevent noise and current leakage during analog measurement.

ADC Pin Configuration

```

*   PFS Register for ADC:
*   +-----+-----+-----+-----+
*   | ASEL | ISEL | Rsvd | PSEL[4:0] |
*   |  1  |  0  |  0  |   0x00   |
*   +-----+-----+-----+-----+
*   ^
*   +-- Set to 1 for analog input
*

```

Common ADC Pins (STAR Project)

Pin	ADC Channel	Typical Use
P40	AN000	Motor 0 current sense
P41	AN001	Motor 1 current sense
P42	AN002	Motor 2 current sense
P43	AN003	Motor 3 current sense
P44	AN004	Analog input (unused)
P45	AN005	Temperature sensor

Parameters

in	pin	GPIO pin identifier for ADC input
		• Must be a pin connected to ADC channel • Typically P40-P47 for AN000-AN007

Returns

Error code indicating success or failure

Return values

k_rx_ok	Pin successfully configured for ADC input
k_rx_err_invalid_arg	Invalid port or pin number

Precondition

Pin must be connected to ADC channel (not all pins support ADC)

PCLKB clock must be running

Postcondition

PFS register has ASEL = 1 (digital buffer disabled)

Pin ready for analog signal input

Note

Digital input buffer disabled - do not use as GPIO input

Also requires S12ADC configuration for actual conversion

Warning

Using a non-ADC pin with this function sets ASEL but has no effect on analog capability (pin hardware determines ADC availability)

Example - Current Sensing Setup

```
// Configure ADC pins for motor current sensing
rx_mpc_set_adc(k_port_4_pin_0); // AN000 = Motor 0 current
rx_mpc_set_adc(k_port_4_pin_1); // AN001 = Motor 1 current
rx_mpc_set_adc(k_port_4_pin_2); // AN002 = Motor 2 current
rx_mpc_set_adc(k_port_4_pin_3); // AN003 = Motor 3 current

// Now configure S12ADC for conversion
// (see adc.h)
```

See also

[rx72n_adc_regs.h](#) ADC register definitions

Since

Version 1.0.0

Configures a pin for analog-to-digital conversion by setting the ASEL bit in the PFS register. This disables the digital input buffer to prevent noise during analog measurement.

Precondition

PCLKB clock must be running, MPC not in module stop
pin must encode a valid port/pin combination with analog capability

Postcondition

PFS register contains k_pfs_asel (0x80) for the specified pin
PWPR locked after operation

Note

Thread safety: Not thread-safe
Sets ASEL bit (0x80) rather than PSEL field
Also configure S12ADC for actual conversion

```
// Configure P40 (AN000) for ADC analog input
rx_err_t err = rx_mpc_set_adc(RX_PORT_PIN(4, 0));
if (err != k_rx_ok) {
    // handle error
}
```

01022   * Common ADC pins: P40-P47 (AN000-AN007)
01023   */
01024  return internal_write_pfs(port, pin_num, k_pfs_asel);
01025 }

```

References [internal_write_pfs\(\)](#), [k_mpc_max_pin](#), [k_mpc_port_j](#), [k_pfs_asel](#), and [s_tag](#).

Here is the call graph for this function:

8.89.4.2 rx_mpc_set_gpio()

```

rx_err_t rx_mpc_set_gpio (
    const rx_port_pin_t pin) [nodiscard]

```

Configure pin for GPIO (General Purpose I/O) function.

Sets the pin to GPIO mode by writing 0x00 to its PFS register (PSEL=0, ISEL=0, ASEL=0). This disconnects the pin from all peripheral functions and allows it to be controlled by PORT PDR/PODR registers.

Algorithm Steps

1. Extract port number and pin number from encoded pin parameter
2. Validate port is in valid range [0, J]
3. Validate pin number is in valid range [0, 7]
4. Calculate PFS register address for this pin
5. Unlock PWPR write protection (B0WI=0, PFSWE=1)
6. Write 0x00 to PFS register (GPIO mode)
7. Lock PWPR write protection (PFSWE=0, B0WI=1)
8. Return success

Parameters

in	pin	GPIO pin identifier (<code>rx_port_pin_t</code> from <code>rx_port_constants.h</code>) - Encodes both port (A-J) and pin number (0-7) - Use <code>k_port_X_pin_Y</code> constants for type safety - Example: <code>k_port_e_pin_5</code> for PE5
----	-----	--

Returns

Error code indicating success or failure

Return values

<code>k_rx_ok</code>	Pin successfully configured for GPIO mode
<code>k_rx_err_invalid_arg</code>	Port number exceeds valid range (> Port J); Pin number exceeds 7; Port not available on package (G/H on 144-pin)

Precondition

PCLKB clock must be running (MPC register access requires it)

MPC module stop bit must be cleared (`MSTPCRA.MSTPA9 = 0`)

Postcondition

PFS register for specified pin contains 0x00

Pin is disconnected from all peripheral functions

PWPR is locked (`B0WI=1`) after operation

Invariant

MPC base address 0x0008C100 remains constant

Other pins' PFS registers are not modified

Note

Not thread-safe. Use mutex protection if calling from multiple threads.

This only sets PFS register. To complete GPIO setup, also configure PORT PMR (peripheral mode = 0) and PDR (direction) registers.

Warning

Calling on a pin that doesn't exist on the package returns error but does not cause hardware fault.

Performance

- Execution time: ~1 us @ 240 MHz (PWPR unlock/lock overhead)
- No loops or blocking operations

Thread Safety

Not thread-safe. The PWPR unlock/lock sequence is non-atomic.

Example - Single Pin

```
#include "rx_mpc.h"
#include "rx_port_constants.h"

// Configure PE5 for GPIO (was previously PWM output)
rx_err_t err = rx_mpc_set_gpio(k_port_e_pin_5);
if (err != k_rx_ok) {
    rx_log_error("INIT", "Failed to set PE5 to GPIO mode");
    return err;
}

// Now configure PORT registers for GPIO operation
// (set PMR=0, configure PDR for direction, etc.)
```

Example - Error Handling

```
// Attempt to configure invalid pin
rx_err_t err = rx_mpc_set_gpio(k_port_g_pin_0); // Port G not on 144-pin
if (err == k_rx_err_invalid_arg) {
    rx_log_warn("MPC", "Pin not available on this package");
}
```

Since

Version 1.0.0

NASA Power of 10 Compliance

- Rule 5: [OK] 2 preconditions (clock, module stop), 3 postconditions
- Rule 7: [OK] All internal function returns checked

Sets the specified pin to GPIO mode by writing 0x00 to its PFS register. This disconnects the pin from all peripheral functions and allows it to be controlled by the PORT registers (PDR, PODR, PIDR).

Implementation Details

1. Extract port and pin number from encoded rx_port_pin_t
2. Validate port is in range [0, J]
3. Validate pin is in range [0, 7]
4. Write 0x00 to PFS register (via internal_write_pfs)

Precondition

PCLKB clock running, MPC not in module stop
pin must be a valid rx_port_pin_t constant

Postcondition

PFS register = 0x00 (GPIO mode)
PWPR locked after operation

Note

Thread safety: Not thread-safe
Also set PORT PMR bit to 0 for complete GPIO configuration

```
// Configure P30 (port 3, pin 0) for GPIO use
rx_err_t err = rx_mpc_set_gpio(RX_PORT_PIN(3, 0));
if (err != k_rx_ok) {
    // handle error
}
```

Here is the call graph for this function:

8.89.4.3 rx`mpc`set`gptw()

```
rx_err_t rx_mpc_set_gptw (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for GPTW (General PWM Timer) complementary output.

Configures a pin for GPTW operation by setting PSEL = 0x1E. GPTW provides complementary PWM output with dead-time insertion for motor control applications.

GPTW channels support:

- 20 kHz PWM frequency (ultrasonic, inaudible)
- 1 us dead-time (prevents DRV8263H shoot-through)
- 90-degree phase staggering (reduces peak current)
- IN2/IN1 mode (direction and PWM signals per DRV8263H)

STAR Project GPTW Pin Allocation

Pin	GPTW Ch	Signal	Motor	Description
P2.3	GPTW0	GTIOC0A	0	Motor 0 Direction (IN2)
P1.7	GPTW0	GTIOC0B	0	Motor 0 PWM (IN1)
P2.2	GPTW1	GTIOC1A	1	Motor 1 Direction (IN2)
PC. ↔ 3	GPTW1	GTETRGC	1	Motor 1 PWM (IN1) - GTETRGC at 0x1E on PC3 per Table 23.19
PE. ↔ 3	GPTW2	GTIOC2A	2	Motor 2 Direction (IN2)
P8.6	GPTW2	GTIOC2B	2	Motor 2 PWM (IN1)
PE. ↔ 7	GPTW3	GTIOC3A	3	Motor 3 Direction (IN2)
PC. ↔ 6	GPTW3	GTIOC3A	3	Motor 3 PWM (IN1) - GTIOC3A at 0x1E on PC6 per Table 23.19

Parameters

in	pin	GPIO pin identifier for GPTW function Must be a pin that supports GPTW output (see manual)
----	-----	--

Returns

Error code indicating success or failure

Return values

k_rx_ok	Pin successfully configured for GPTW
k_rx_err_null_ptr	Config pointer is NULL (should never happen)
k_rx_err_invalid_arg	Invalid port or pin number (≥ 16)
k_rx_err_hw_error	PWPR write-protect unlock failed

Precondition

Pin must support GPTW function (check RX72N hardware manual)

PCLKB clock must be running (MPC registers require clock)

Must be called during single-threaded initialization

Postcondition

PFS register configured with PSEL = 0x1E

PWPR register locked (write protection re-enabled)

Pin configured for GPTW PSEL; caller MUST subsequently set the corresponding PORTn.PMR bit (this function does NOT touch PMR) before GPTW can drive the pin.

Note

Thread Safety: Not thread-safe. Call during initialization only.

Configure both direction (A/IN2) and PWM (B/IN1) pins for each motor

GPTW channel configuration required for actual PWM operation

Warning

Motor safety: Configure pins before enabling GPTW channels

Example - Configure All Motor PWM Pins

```
// Configure 8 GPTW pins (4 motors x 2 pins = IN2 + IN1)
const rx_port_pin_t gptw_pins[] = {
    k_rx_p2_3, k_rx_p1_7, // Motor 0 IN2/IN1
    k_rx_p2_2, k_rx_pc_3, // Motor 1 IN2/IN1
    k_rx_pe_3, k_rx_p8_6, // Motor 2 IN2/IN1
    k_rx_pe_7, k_rx_pc_6  // Motor 3 IN2/IN1
};

for (uint8_t i = 0; i < 8; i++) {
    rx_err_t err = rx_mpc_set_gptw(gptw_pins[i]);
    if (err != k_rx_ok) {
        rx_log_error("GPIO", "GPTW pin config failed");
        return err;
    }
}

// Now safe to initialize GPTW channels
rx_gptw_init_all_staggered(&config);
```

 RX72N Manual Chapter 23 - Multi-Function Pin Controller
 RX72N Manual Chapter 29 - General PWM Timer

Since

Version 1.0.0

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, recursion (delegates to rx_mpc_set_peripheral)
- Rule 3: [OK] No dynamic allocation (stack-only config struct)
- Rule 4: [OK] Function is 6 lines (well under 60 line limit)
- Rule 7: [OK] Return value from rx_mpc_set_peripheral checked by caller

Configure pin for GPTW (General PWM Timer) complementary output.

Convenience wrapper that configures a pin for GPTW operation using PSEL = k_psel_gptw (0x1E). GPTW provides complementary PWM output with dead-time insertion for motor control.

Precondition

PCLKB clock must be running, MPC not in module stop
 pin must encode a valid port/pin combination with GPTW multiplexing

Postcondition

PFS register contains k_psel_gptw (0x1E) for the specified pin
 PWPR locked after operation

Note

Thread safety: Not thread-safe
 Used for 4 GPTW channels (0-3) with 8 total pins (IN2 + IN1 per motor)
 Phase staggering configured separately via rx_gptw driver

```
// Configure motor 2 GPTW IN2 and IN1 pins (Port E)
rx_err_t err = rx_mpc_set_gptw(RX_PORT_PIN(0xE, 3)); // PE3 GTIOC2A (IN2)
if (err == k_rx_ok) {
    err = rx_mpc_set_gptw(RX_PORT_PIN(8, 6)); // P8.6 GTIOC2B (IN1)
}
```

Since

Version 1.0.0

Definition at line 1234 of file rx_mpc.c.

```
01235 {
01236     /* GPTW pins use PSEL = 0x1E
01237      * Supports 4 GPTW channels (0-3) for motor IN2/IN1 control */
01238     const rx_mpc_peripheral_config_t config = {
01239         .pin = pin,
01240         .psel = k_psel_gptw /* 0x1E - defined in rx_pin_psel_t enum */
01241     };
01242
01243     return rx_mpc_set_peripheral(&config);
01244 }
```

References [k_psel_gptw](#), and [rx_mpc_set_peripheral\(\)](#).

Here is the call graph for this function:

8.89.4.4 rx_mpc_set_irq()

```
rx_err_t rx_mpc_set_irq (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for IRQ (external interrupt) function.

Sets pin function to IRQ mode via MPC (Multi-Function Pin Controller). This enables hardware edge detection on IRQ0-IRQ15 pins for use with the Interrupt Controller Unit (ICU).

PFS Register for IRQ Function:

- IRQ pins: ISEL bit (bit 6) = 0x40 written directly to PFS register
- This is NOT a PSEL value; [rx_mpc_set_peripheral\(\)](#) is NOT used
- Verify in RX72N Manual Section 20.3 (MPC), PFS register layout

Supported Pins:

- P00-P07: IRQ8-IRQ15
- Other IRQ pins per RX72N Manual Table 20.7

STAR Project IRQ Usage (HC-SR04 Ultrasonic Sensors)

Pin	IRQ Number	Sensor	Location
P03	IRQ11	Sonar 0	Front-Left
P02	IRQ10	Sonar 1	Front-Right
P01	IRQ9	Sonar 2	Back-Left
P00	IRQ8	Sonar 3	Back-Right

Parameters

in	pin	GPIO pin identifier (must support IRQ function) Use k_rx_p0_X constants for IRQ8-15
----	-----	---

Returns

rx_err_t Error code

Return values

k_rx_ok	Pin configured for IRQ function
k_rx_err_invalid_arg	Invalid port or pin number (propagated from internal_write_pfs())

Note

[internal_mpc_unlock\(\)](#) and [internal_mpc_lock\(\)](#) do not propagate errors; only [internal_write_pfs\(\)](#) can return k_rx_err_invalid_arg on invalid port/pin values.

Precondition

Pin must have IRQ multiplexing capability (P00-P07 for IRQ8-15)
PCLKB running (MPC requires clock)
Must be called during single-threaded initialization

Postcondition

Pin ISEL bit set (0x40) in PFS register (IRQ input mode)
PSEL field remains 0 (no conflicting peripheral function)
PWPR register locked
Pin ready for ICU edge detection configuration

Note

Thread Safety: Not thread-safe. Call during initialization only.
Call this BEFORE enabling ICU interrupt

Warning

Does NOT configure ICU registers (edge detect, priority, etc.)
 Configure ICU separately for edge detection and priority as required

Example - IRQ Pin Setup

```
// Configure P03 for IRQ11 (external interrupt input)
rx_err_t err = rx_mpc_set_irq(k_rx_p0_3);
if (err != k_rx_ok) {
    rx_log_error("IRQ", "IRQ pin configuration failed");
    return err;
}

// Now configure ICU for edge detection (caller-specific step)
```

Invariant

MPC base address remains constant throughout operation
 Only target pin's PFS register is modified (other pins' PFS unchanged)

See also

[rx_mpc_set_gpio\(\)](#) Set pin back to GPIO mode
 RX72N Manual Section 20.3 (MPC), PFS register bit definitions
 RX72N Manual Chapter 15 (ICU - Interrupt Controller Unit)

Since

Version 1.0.0

NASA Power of 10 Compliance

- Rule 5: [OK] 3 preconditions, 4 postconditions
- Rule 7: [OK] Caller checks return value ([[nodiscard]])
- Rule 8: [OK] k_pfs_isel from [pfs_bits_t](#) enum (no magic numbers)

Sets pin function to IRQ mode by writing the ISEL bit (bit 6, value 0x40) directly to the PFS register via [internal_write_pfs\(\)](#). This bypasses [rx_mpc_set_peripheral\(\)](#) because ISEL=0x40 exceeds the 5-bit PSEL field maximum (k_mpc_psel_max = 31).

Mirrors the approach used by [rx_mpc_set_adc\(\)](#) for ASEL (bit 7): both functions write their respective bit directly rather than going through the PSEL validation path.

Algorithm Steps:

1. Extract port number and pin number from encoded pin parameter
2. Validate port in range [0, J]
3. Validate pin in range [0, 7]
4. Write ISEL bit (0x40) to PFS register via [internal_write_pfs\(\)](#)

Precondition

Pin must have IRQ multiplexing capability (P00-P07 for IRQ8-15)
PCLKB clock must be running

Postcondition

Pin ISEL bit (0x40) set in PFS register
PSEL field remains 0 (no peripheral function conflict)

Note

Thread safety: Not thread-safe
Typical pins: P00-P07 for IRQ8-IRQ15 on RX72N
Used by HC-SR04 ultrasonic sensors for echo pulse measurement

```
// Configure P00 for IRQ8 (HC-SR04 echo input)
rx_err_t err = rx_mpc_set_irq(RX_PORT_PIN(0, 0));
if (err != k_rx_ok) {
    // handle error
}
// Then configure ICU for rising/falling edge detection
```

01337 {
01338     /* Extract port and pin number from type-safe enum */
01339     const uint8_t port = rx_port_from_pin(pin);
01340     const uint8_t pin_num = rx_pin_from_pin(pin);
01341
01342     /* Validate the decoded port and pin are in valid range */
01343     if (port > k_mpc_port_j || pin_num > k_mpc_max_pin) {
01344         rx_log_error(s_tag, "Invalid port or pin number for IRQ function");
01345         return k_rx_err_invalid_arg;
01346     }
01347
01348     /* IRQ mode: Set ISEL = 1 (bit 6) to enable IRQ input function.
01349     * This is NOT a PSEL value; k_pfs_isel is 0x40 which exceeds the 5-bit
01350     * PSEL field. Write directly like rx_mpc_set_adc() does for ASEL.
01351     * Typical IRQ pins: P00-P07 (IRQ8-IRQ15) for HC-SR04 echo measurement. */
01352     return internal_write_pfs(port, pin_num, k_pfs_isel);
01353 }
```

References [internal_write_pfs\(\)](#), [k_mpc_max_pin](#), [k_mpc_port_j](#), [k_pfs_isel](#), and [s_tag](#).

Here is the call graph for this function:

8.89.4.5 rx_mpc_set_mtu_encoder()

```
rx_err_t rx_mpc_set_mtu_encoder (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for MTU3a encoder/phase counter input (MTCLK).

Configures a pin for MTU3a phase counting mode input, used with quadrature encoders. Sets PSEL = k_psel_mtu_phase (0x03) for phase counting with direction detection.

Quadrature Encoder Interface

```
* Encoder Output      MTU3a Phase Counting
* +-----+          +-----+
* | Phase A |----->| MTCLKA (Count Up) |
* | Phase B |----->| MTCLKB (Count Down) |
* | (Index Z) |----->| (Optional reset) |
* +-----+          +-----+
*                               Counter increments/decrements
*                               based on phase relationship
*
```

Common Encoder Pins (STAR Project)

Pin Pair	MTU Input	Encoder
P24/P25	MTCLKA/MTCLKB	Motor 0
PC0/PC1	MTCLKC/MTCLKD	Motor 1

Parameters

in	pin	GPIO pin identifier for encoder input
		- Must be a pin that supports MTCLK function - Configure in pairs (A+B) for quadrature

Returns

Error code indicating success or failure

Return values

k_rx_ok	Pin successfully configured for encoder input
k_rx_err_invalid_arg	Invalid port or pin number

Precondition

Pin must support MTU clock/phase function

PCLKB clock must be running

Postcondition

PFS register contains PSEL = 0x03 (MTU phase)

Pin ready for quadrature encoder input

Note

Configure both Phase A and Phase B pins for proper operation

Also requires MTU3a timer configuration in phase counting mode

Example - Quadrature Encoder Setup

```
// Configure encoder pins for Motor 0
rx_err_t err;

err = rx_mpc_set_mtu_encoder(k_port_2_pin_4); // P24 = Phase A
if (err != k_rx_ok) return err;

err = rx_mpc_set_mtu_encoder(k_port_2_pin_5); // P25 = Phase B
if (err != k_rx_ok) return err;

// Now configure MTU1 for phase counting mode
// (see rx_mtu_encoder.h)
```

See also

[rx_mpc_set_peripheral\(\)](#) Underlying implementation

[rx_mtu_encoder.h](#) Encoder driver using MTU phase counting

Since

Version 1.0.0

Convenience wrapper that configures a pin for MTU external clock / phase counting mode using PSEL = k_psel_mtu_phase (0x02). Used for quadrature encoders on pins that expose MTCLKA/B/C/D.

Precondition

PCLKB clock must be running, MPC not in module stop

pin must encode a valid port/pin combination supported by MTCLK input

Postcondition

PFS register contains k_psel_mtu_phase (0x02) for the specified pin

WPWR locked after operation

Note

Thread safety: Not thread-safe

Configure both Phase A and Phase B pins for proper operation

```
// Configure P24 and P25 for MTU phase counting (MTCLKA/B)
rx_err_t err = rx_mpc_set_mtu_encoder(RX_PORT_PIN(2, 4));
if (err == k_rx_ok) {
    err = rx_mpc_set_mtu_encoder(RX_PORT_PIN(2, 5));
}
```

00918     * PA1/PC5 (Motor 1 front-left MTCLKC/D)
00919     */
00920     const rx_mpc_peripheral_config_t config = {.pin = pin, .psel = k_psel_mtu_phase};
00921
00922     return rx_mpc_set_peripheral(&config);
00923 }

```

References [k_psel_mtu_phase](#), and [rx_mpc_set_peripheral\(\)](#).

Here is the call graph for this function:

8.89.4.6 rx_mpc_set_mtu_pwm()

```

rx_err_t rx_mpc_set_mtu_pwm (
    const rx_port_pin_t pin)    [nodiscard]

```

Configure pin for MTU3a timer PWM output (MTIOC).

Convenience function that configures a pin for MTU3a I/O compare output, used for PWM generation. Internally calls [rx_mpc_set_peripheral\(\)](#) with PSEL = k_psel_mtu_ioc (0x01).

Common MTU PWM Pins

Pin	MTU Channel	Output	Typical Use
P14	MTU3	MTIOC3A	Motor 0 Phase A
P15	MTU3	MTIOC3B	Motor 0 Phase B
P16	MTU3	MTIOC3C	Motor 0 Phase C

Pin	MTU Channel	Output	Typical Use
P17	MTU3	MTIOC3D	Motor 0 Phase D
P24	MTU4	MTIOC4A	Motor 1 Phase A
P25	MTU4	MTIOC4B	Motor 1 Phase B
P26	MTU4	MTIOC4C	Motor 1 Phase C
P27	MTU4	MTIOC4D	Motor 1 Phase D

Parameters

in	pin	GPIO pin identifier for MTU PWM output - Must be a pin that supports MTIOC function - Use k_port_X_pin_Y constants
----	-----	---

Returns

Error code indicating success or failure

Return values

k_rx_ok	Pin successfully configured for MTU PWM
k_rx_err_invalid_arg	Invalid port or pin number

Precondition

Pin must support MTU I/O compare function (check hardware manual)

PCLKB clock must be running

Postcondition

PFS register contains PSEL = 0x01 (MTU IOC)

Pin ready for MTU3a compare match output

Note

Also requires MTU3a timer configuration and PORT PMR=1

STAR project uses GPTW for motor PWM; see [rx_mpc_set_gptw\(\)](#) which uses PSEL = k_psel_gptw (0x1E)

Example

```
// Configure P14-P17 for MTU3 PWM outputs
rx_mpc_set_mtu_pwm(k_port_1_pin_4); // MTIOC3A
rx_mpc_set_mtu_pwm(k_port_1_pin_5); // MTIOC3B
rx_mpc_set_mtu_pwm(k_port_1_pin_6); // MTIOC3C
rx_mpc_set_mtu_pwm(k_port_1_pin_7); // MTIOC3D
```

See also

[rx_mpc_set_peripheral\(\)](#) Underlying implementation
[rx_mtu.h](#) MTU timer driver

Since

Version 1.0.0

Convenience wrapper that configures a pin for MTU I/O compare output using PSEL = k_psel_mtu_ioc (0x01). Commonly used for motor PWM.

Precondition

PCLKB clock must be running, MPC not in module stop
 pin must encode a valid port/pin combination supported by MTU MTIOC

Postcondition

PFS register contains k_psel_mtu_ioc (0x01) for the specified pin
 PWPR locked after operation

Note

Thread safety: Not thread-safe

STAR project uses GPTW for motor PWM (see [rx_mpc_set_gptw\(\)](#), PSEL = k_psel_gptw (0x1E)), not MTU

```
// Configure P14 for MTU3 PWM output (MTIOCA)
rx_err_t err = rx_mpc_set_mtu_pwm(RX_PORT_PIN(1, 4));
if (err != k_rx_ok) {
    // handle error
}
```

See also

[rx_mpc.h](#) Full API documentation

Since

Version 1.0.0

Definition at line 863 of file [rx_mpc.c](#).

```
00864 {
00865     /* MTU PWM (MTIOC) pins typically use PSEL = 0x01
00866     * Common pins:
00867     * - P14-P17: MTU3 MTIOCA/B/C/D
00868     * - P24-P27: MTU4 MTIOCA/B/C/D
00869     */
00870     const rx_mpc_peripheral_config_t config = {.pin = pin, .psel = k_psel_mtu_ioc};
00871
00872     return rx_mpc_set_peripheral(&config);
00873 }
```

References [k_psel_mtu_ioc](#), and [rx_mpc_set_peripheral\(\)](#).

Here is the call graph for this function:

8.89.4.7 rx_mpc_set_peripheral()

```
rx_err_t rx_mpc_set_peripheral (
    const rx_mpc_peripheral_config_t * config) [nodiscard]
```

Configure pin for peripheral function with specified PSEL code.

Core function for pin multiplexer configuration. Writes the specified PSEL value to the pin's PFS register, connecting the pin to a peripheral function. Uses a configuration structure to prevent parameter swapping.

Algorithm Steps

1. Validate config pointer is not nullptr
2. Validate PSEL value is in range [0, 31]
3. Extract port number and pin number from config->pin
4. Validate extracted port and pin are in valid ranges
5. Calculate PFS register address for this pin
6. Unlock PWPR write protection (B0WI=0, PFSWE=1)
7. Write config->psel to PFS register
8. Lock PWPR write protection (PFSWE=0, B0WI=1)
9. Return success

Parameters

in	config	Pointer to MPC peripheral configuration structure • config->pin: Target pin (rx_port_pin_t constant) • config->psel: PSEL value to write (0-31) • Must not be nullptr • Must remain valid only during function call
----	--------	--

Returns

Error code indicating success or failure

Return values

k_rx_ok	Pin successfully configured for peripheral function
k_rx_err_invalid_arg	config pointer is nullptr; config->psel exceeds 31 (5-bit field max); Port number exceeds valid range; Pin number exceeds 7; Port not available on package

Precondition

config pointer must be non-NULL
 config->psel must be in range [0, 31]
 config->pin must be a valid rx_port_pin_t value
 PCLKB clock must be running

Postcondition

PFS register for specified pin contains config->psel value
 Pin is connected to peripheral function specified by PSEL
 PWPR is locked (B0WI=1) after operation

Invariant

config structure is not modified (const pointer)
 Other pins' PFS registers are not modified

Note

Not thread-safe. Use mutex protection if calling from multiple threads.
 This only sets PFS register. For peripheral operation, also set PORT PMR bit to 1 to enable peripheral mode.
 PSEL values are pin-specific. Verify correct value in hardware manual.

Warning

Wrong PSEL value may connect pin to unexpected peripheral!
 Not all PSEL values are valid for all pins.

Performance

- Execution time: ~1 us @ 240 MHz
- No loops or blocking operations

Thread Safety

Not thread-safe. The PWPR unlock/lock sequence is non-atomic.

Example - Motor PWM Configuration

```
#include "rx_mpc.h"
#include "rx_port_constants.h"

// Configure PE5 for GPTW0A (Motor 0 PWM Phase+)
rx_mpc_peripheral_config_t pwm_config = {
    .pin = k_port_e_pin_5, // PE5
    .psel = k_psel_gptw // GPTW function (0x1E)
};

rx_err_t err = rx_mpc_set_peripheral(&pwm_config);
if (err != k_rx_ok) {
    rx_log_error("MOTOR", "PWM pin configuration failed");
    return err;
}

// Don't forget: Set PORT PMR bit to enable peripheral mode!
```

Example - Batch Configuration

```
// Configure multiple pins in a loop
const rx_mpc_peripheral_config_t pins[] = {
    { k_port_e_pin_5, k_psel_gptw }, // GPTW0A (0x1E)
    { k_port_e_pin_4, k_psel_gptw }, // GPTW0B (0x1E)
    { k_port_2_pin_4, 0x02 }, // MTCLKA
    { k_port_2_pin_5, 0x02 }, // MTCLKB
};

for (size_t i = 0; i < sizeof(pins)/sizeof(pins[0]); i++) {
    rx_err_t err = rx_mpc_set_peripheral(&pins[i]);
    if (err != k_rx_ok) {
        rx_log_error("MPC", "Pin config failed");
        return err;
    }
}
```

Since

Version 1.0.0

NASA Power of 10 Compliance

- Rule 5: [OK] 4 preconditions, 3 postconditions
- Rule 7: [OK] All return values checked

Core function for peripheral pin configuration. Writes the specified PSEL value to the pin's PFS register, connecting it to a peripheral.

Implementation Details

1. Validate config pointer is not nullptr
2. Validate PSEL value is in range [0, 31]
3. Extract port and pin from config->pin
4. Validate extracted values
5. Write PSEL to PFS register (via internal_write_pfs)

Precondition

config must be non-NULL with valid fields
PCLKB clock running

Postcondition

PFS register contains config->psel
PWPR locked after operation

Note

Thread safety: Not thread-safe
Also set PORT PMR bit to 1 for peripheral mode

```
// Configure PA0 for RSPI clock (PSEL = 0x0D)
const rx_mpc_peripheral_config_t cfg = {
    .pin = RX_PORT_PIN(0xA, 0),
    .psel = 0x0D,
};
rx_err_t err = rx_mpc_set_peripheral(&cfg);
if (err != k_rx_ok) {
    // handle error
}
```

8.89.4.8 rx_mpc_set_riic()

```
rx_err_t rx_mpc_set_riic (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for RIIC (I2C) bus function.

Configures a pin for RIIC (Renesas I2C) operation by setting PSEL = 0x0F. Works for both SCL (clock) and SDA (data) pins. RIIC hardware automatically configures the open-drain output when the channel is enabled.

I2C Bus Pins

Pin	RIIC Channel	Function	Notes
P12	RIIC0	SCL0	Clock line
P13	RIIC0	SDA0	Data line

Parameters

in	pin	GPIO pin identifier for RIIC function
		Must be a pin that supports RIIC SCL/SDA

Returns

Error code indicating success or failure

Return values

k_rx_ok	Pin successfully configured for RIIC I2C
k_rx_err_invalid_arg	Invalid port or pin number

Precondition

Pin must support RIIC function
PCLKB clock must be running

Postcondition

PFS register contains PSEL = 0x0F
Pin ready for I2C operation

Note

Configure both SCL and SDA pins
External pull-up resistors required (typically 4.7kOhm)
Also requires RIIC channel configuration

Example - I2C Bus Setup

```
// Configure I2C pins (RIIC0)
rx_mpc_set_riic(k_port_1_pin_2); // P12 = SCL0
rx_mpc_set_riic(k_port_1_pin_3); // P13 = SDA0

// Now configure RIIC0
// (see riic.h)
```

See also

[rx72n_riic_regs.h](#) RIIC register definitions

Since

Version 1.0.0

Convenience wrapper that configures a pin for RIIC operation using PSEL = k_psel_riic_scl (0x0F). Works for both SCL and SDA pins.

Unlike [rx_mpc_set_gptw\(\)](#), this function also sets PORT.PMR=1 for the pin before returning – RIIC cannot drive SDA/SCL while PMR=0 and the immediate-vs-deferred PMR trade-off differs from the motor-PWM case:

Peripheral	When to raise PMR	Reason
GPTW/PWM	AFTER timer is running	Push-pull drive: an un-
	(rx_gptw_init_pwm handles	initialized output could
	this after rx_gptw_start)	momentarily glitch
		DRV8263H H-bridge inputs
		to Vm/2 during the
		GTIOR reset state window.
RIIC/I2C	IMMEDIATELY after PFS	Open-drain + external
	(here, inside this wrapper)	pull-ups: idle bus is
		both lines high (3.3V);
		routing an un-initialized
		RIIC just leaves the
		pull-ups floating the
		lines high. No hazard.

Without PMR=1 on the RIIC pins, rx72n peripheral bits still toggle internally but the pad stays disconnected from RIIC; every Start condition times out with k_rx_err_timeout (0x108) at the first [riic_write\(\)](#)/[riic_read\(\)](#) call. Discovered 2026-04-22: production imu_task saw tight "[ERROR] [RIIC] Start condition timeout" loops while imu_test/main.c (which sets PMR=1 at line 227 before calling its own [riic_init\(\)](#)) talked to BNO055 + BMP280 cleanly on the same board.

Precondition

PCLKB clock must be running, MPC not in module stop

pin must encode a valid port/pin combination with RIIC multiplexing

Postcondition

PFS register contains `k_psel_riic_scl` (0x0F) for the specified pin
 PORT.PMR bit for the pin is set (pin routed to RIIC peripheral)
 PWPR locked after operation

Note

Thread safety: Not thread-safe
 Configure both SCL and SDA pins; external pull-ups required

```
// Configure P12 (SCL) and P13 (SDA) for RIIC0
rx_err_t err = rx_mpc_set_riic(RX_PORT_PIN(1, 2));
if (err == k_rx_ok) {
    err = rx_mpc_set_riic(RX_PORT_PIN(1, 3));
}
```

8.89.4.9 rx'mpc'set'rspi()

```
rx_err_t rx_mpc_set_rspi (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for RSPI (SPI) bus function.

Configures a pin for RSPI (Renesas SPI) operation by setting PSEL = 0x0D. Works for all SPI signals: RSPCK (clock), COPI (data out), CIPO (data in), and SSLn (chip select).

STAR Project SPI Configuration (RPi5 Communication)

Note: RSPI0 Signal names (MOSIA/MISOA) are RX72N datasheet hardware names. Function names (COPI/CIPO) are project terminology per OSHWA standards.

Pin	RSPI0 Signal	Function	Description
PA0	MOSIA	COPI	Controller Out, Peripheral In
PA1	MISOA	CIPO	Controller In, Peripheral Out
PA3	RSPCKA	CLK	SPI clock
PA4	SSLA0	CS	Chip select (active low)

SPI Bus Topology

```

*   RX72N (Controller)           RPi5 (Controller)
*   +-----+                   +-----+
*   | RSPi0      |             | SPI      |
*   | PA0 (COPI)  <-----+-----> CIPO    |
*   | PA1 (CIPO)  <-----+-----> COPI    |
*   | PA3 (CLK)   <-----+-----> CLK     |
*   | PA4 (CS)    <-----+-----> CS      |
*   +-----+                   +-----+
*   Note: RX72N is SPI peripheral, RPi5 is controller
*

```

Parameters

in	pin	GPIO pin identifier for RSPi function
		Must be a pin that supports RSPi signals

Returns

Error code indicating success or failure

Return values

k_rx_ok	Pin successfully configured for RSPi SPI
k_rx_err_invalid_arg	Invalid port or pin number

Precondition

Pin must support RSPi function

PCLKB clock must be running

Postcondition

PFS register contains PSEL = 0x0D

Pin ready for SPI operation

Note

Configure all 4 SPI pins (CLK, COPI, CIPO, CS)

Also requires RSPi channel configuration

Uses OSHWA-approved inclusive terminology (COPI/CIPO)

Example - SPI Bus Setup

```

// Configure SPI pins for RPi5 communication (RSPi0)
rx_mpc_set_rspi(k_port_a_pin_0); // PA0 = COPI
rx_mpc_set_rspi(k_port_a_pin_1); // PA1 = CIPO
rx_mpc_set_rspi(k_port_a_pin_3); // PA3 = CLK
rx_mpc_set_rspi(k_port_a_pin_4); // PA4 = CS (CS)

// Now configure RSPi0
// (see rspi.h)

```

8.89.4.10 rx_mpc_set_sci()

```
rx_err_t rx_mpc_set_sci (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for SCI (Serial Communication Interface) UART function.

Configures a pin for SCI UART operation by setting PSEL = 0x0A. Works for both TXD (transmit) and RXD (receive) pins - the same PSEL value is used, with the specific function determined by the pin's hardware connection.

STAR Project UART Configuration (Debug Console)

Pin	SCI Channel	Function	Notes
PB7	SCI9	TXD9	Debug output
PB6	SCI9	RXD9	Debug input

Parameters

in	pin	GPIO pin identifier for SCI function
		Must be a pin that supports SCI TXD/RXD

Returns

Error code indicating success or failure

Return values

k_rx_ok	Pin successfully configured for SCI UART
k_rx_err_invalid_arg	Invalid port or pin number

Precondition

Pin must support SCI function (check hardware manual)

PCLKB clock must be running

Postcondition

PFS register contains PSEL = 0x0A

Pin ready for UART operation

Note

Configure both TXD and RXD pins for bidirectional UART

Also requires SCI channel configuration and PORT PMR=1

Example - Debug UART Setup

```
// Configure debug UART pins (SCI9)
rx_mpc_set_sci(k_port_b_pin_7); // PB7 = TXD9
rx_mpc_set_sci(k_port_b_pin_6); // PB6 = RXD9

// Now configure SCI9 for UART mode
// (see uart.h)
```

See also

[rx72n_sci_regs.h](#) SCI register definitions

Since

Version 1.0.0

Convenience wrapper that configures a pin for SCI UART operation using PSEL = k_psel_sci_tx (0x0A). Works for both TXD and RXD pins.

Precondition

PCLKB clock must be running, MPC not in module stop
pin must encode a valid port/pin combination with SCI multiplexing

Postcondition

PFS register contains k_psel_sci_tx (0x0A) for the specified pin
PWPR locked after operation

Note

Thread safety: Not thread-safe
Configure both TXD and RXD pins for bidirectional UART

```
// Configure PB7 for SCI9 TXD
rx_err_t err = rx_mpc_set_sci(RX_PORT_PIN(0xB, 7));
if (err != k_rx_ok) {
    // handle error
}
```

8.89.4.11 `rx_mpc_set_tpu_encoder()`

```
rx_err_t rx_mpc_set_tpu_encoder (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for TPU encoder/phase counter input (TCLK).

Configures a pin for TPU phase counting mode input, used with quadrature encoders on the rear wheels. Sets PSEL = `k_psel_mtu_phase` (0x03), which is the generic "timer phase counting input" function on the RX72N. The routing to TPU (vs MTU) depends on which timer module has phase counting mode enabled.

This function exists as a separate API from `rx_mpc_set_mtu_encoder()` for documentation clarity, even though both write the same PSEL value.

TPU Encoder Pins (STAR Project - Rear Wheels)

Pin Pair	TPU Input	Encoder
PC2/PA3	TCLKA/TCLKB	Motor 2 (Rear Left)
PC0/PB3	TCLKC/TCLKD	Motor 3 (Rear Right)

Parameters

in	pin	GPIO pin identifier for TPU encoder input
		- Must be a pin that supports TCLK function - Configure in pairs (A+B) for quadrature

Returns

Error code indicating success or failure

Return values

k_rx_ok	Pin successfully configured for TPU encoder input
k_rx_err_invalid_arg	Invalid port or pin number

Precondition

Pin must support TPU clock/phase function
PCLKB clock must be running

Postcondition

PFS register contains PSEL = 0x03 (timer phase counting)
Pin ready for quadrature encoder input via TPU

Note

Configure both Phase A and Phase B pins for proper operation
Also requires TPU timer configuration in phase counting mode

Example - Rear Wheel Encoder Setup

```
rx_err_t err;

// Motor 2 (Rear Left) - TPU1
err = rx_mpc_set_tpu_encoder(k_rx_pc_2); // PC2 = TCLKA (Phase A)
if (err != k_rx_ok) return err;
err = rx_mpc_set_tpu_encoder(k_rx_pa_3); // PA3 = TCLKB (Phase B)
if (err != k_rx_ok) return err;

// Motor 3 (Rear Right) - TPU2
err = rx_mpc_set_tpu_encoder(k_rx_pc_0); // PC0 = TCLKC (Phase A)
if (err != k_rx_ok) return err;
err = rx_mpc_set_tpu_encoder(k_rx_pb_3); // PB3 = TCLKD (Phase B)
if (err != k_rx_ok) return err;
```

See also

[rx_mpc_set_mtu_encoder\(\)](#) Front wheel encoder pin configuration
[rx_mpc_set_peripheral\(\)](#) Underlying implementation
[rx_encoder_tpu.h](#) TPU encoder driver using phase counting

Since

Version 1.0.0

Convenience wrapper that configures a pin for TPU external clock input (TCLKA/B/C/D). Picks the correct PSEL value based on which port the pin is on, because RX72N uses two different alternate-function slots for the SAME TCLK signal depending on candidate:

- Port C pins (PC0/PC1/PC2/PC3) use PSEL = 0x03 (`k_psel_tpu_clk_portc`)
- Port 1 / Port A / Port B pins use PSEL = 0x04 (`k_psel_tpu_clk_alt`)

Reference: RX72N Group Hardware Manual (R01UH0824EJ0111), chapter 23 "Multi-Function Pin Controller (MPC)". TCLK rows in Table 23.19 (Port C) use PSEL = 000011b, while TCLK rows in Tables 23.5 (P1x), 23.17 (PAx), and 23.18 (PBx) use PSEL = 000100b. Before this split, every TPU pin was configured with PSEL=0x03, which silently misconfigured the non-Port-C halves of STAR's rear-wheel encoders (PA3 for Motor 2 Phase B, PB3 for Motor 3 Phase B) so those edges were never counted.

Precondition

PCLKB clock must be running, MPC not in module stop
 pin must encode a valid port/pin combination supported by TCLK input

Postcondition

PFS register contains the correct TPU-TCLK PSEL for that pin's port
 PWPR locked after operation

Note

Thread safety: Not thread-safe
 Configure both Phase A and Phase B pins for proper operation

```
// Configure PC2 (TCLKA) and PA3 (TCLKB) for Motor 2 rear-left encoder
rx_err_t err = rx_mpc_set_tpu_encoder(RX_PORT_PIN(0xC, 2)); // -> 0x03
if (err == k_rx_ok) {
    err = rx_mpc_set_tpu_encoder(RX_PORT_PIN(0xA, 3));      // -> 0x04
}
```

Here is the call graph for this function:

8.89.4.12 rx_mpc_set_usb_vbus()

```
rx_err_t rx_mpc_set_usb_vbus (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for USB VBUS detection function.

Configures a pin for USB VBUS detection by setting PSEL = 0x11. VBUS detection is used for USB enumeration and power presence sensing.

The VBUS detect pin monitors the 5V power rail on the USB bus:

- Pin reads HIGH (1) when USB cable connected and 5V present
- Pin reads LOW (0) when USB cable disconnected or unpowered

Required for USB CDC communication with RPi5 host.

STAR Project USB Configuration

Pin	Function	Description
P1.↔ 6	USB0_VBUS	VBUS detect (5V presence)

Parameters

in	pin	GPIO pin identifier for USB VBUS detect Typically P1.6 for USB0_VBUS on RX72N
----	-----	---

Returns

Error code indicating success or failure

Return values

k_rx_ok	Pin successfully configured for USB VBUS
k_rx_err_null_ptr	Config pointer is NULL (should never happen)
k_rx_err_invalid_arg	Invalid port or pin number
k_rx_err_hw_error	PWPR write-protect unlock failed

Precondition

Pin must support USB VBUS function (P1.6 on RX72N)

PCLKB clock must be running

Must be called during single-threaded initialization

Postcondition

PFS register configured with PSEL = 0x11

PWPR register locked

Pin configured for USB VBUS PSEL; caller MUST subsequently set the corresponding PORTn.
PMR bit (this function does NOT touch PMR) before the USB peripheral sees the VBUS signal.

Note

Thread Safety: Not thread-safe. Call during initialization only.

Active-high detection (pin = 1 when 5V present)

Also requires USB PHY and USB0 controller configuration

Example - USB VBUS Setup

```
// Configure USB VBUS detect pin (P1.6)
rx_err_t err = rx_mpc_set_usb_vbus(k_rx_p1_6);
if (err != k_rx_ok) {
    rx_log_error("USB", "VBUS pin configuration failed");
    return err;
}

// Now configure USB0 controller
err = usb_init(USB_MODE_CDC);
```

Definition at line 1278 of file [rx_mpc.c](#).

```
01279 {
01280     /* USB VBUS detect uses PSEL = 0x11
01281      * Typical pin: P1.6 for USB0_VBUS on RX72N */
01282     const rx_mpc_peripheral_config_t config = {
01283         .pin = pin,
01284         .psel = k_psel_usb_vbus /* 0x11 - defined in rx_pin_psel_t enum */
01285     };
01286
01287     return rx_mpc_set_peripheral(&config);
01288 }
```

References [k_psel_usb_vbus](#), and [rx_mpc_set_peripheral\(\)](#).

Here is the call graph for this function:

```

00083 * | MPC Base | 0x0008C100 | Fixed hardware address |
00084 * | PCLKB | Active | Required for register access |
00085 * | MSTPCRA | Bit 9 = 0 | MPC module stop cleared |
00086 *
00087 * @par Performance Characteristics
00088 * | Operation | Typical Time | Notes |
00089 * |-----|-----|-----|
00090 * | Pin config | ~1 us | PWPR unlock/lock overhead |
00091 * | Bulk config (10 pins) | ~10 us | Sequential calls |
00092 *
00093 * @par Memory Usage
00094 * | Category | Size | Notes |
00095 * |-----|-----|-----|
00096 * | Code | ~800 bytes | All functions |
00097 * | Static data | 4 bytes | Tag string only |
00098 * | Stack (per call) | 16 bytes | Local variables |
00099 *
00100 * @par Thread Safety
00101 * **Not thread-safe.** The MPC PWPR unlock/lock sequence is non-atomic.
00102 * If multiple threads call MPC functions concurrently, race conditions can
00103 * occur where one thread's unlock is clobbered by another's lock. Use
00104 * external mutex protection or configure all pins during single-threaded
00105 * initialization before starting RTOS.
00106 *
00107 * @par Initialization Order
00108 * MPC configuration should occur early in system initialization:
00109 * 1. Clock configuration (PCLKB must be running)
00110 * 2. Module stop clear (if MPC in module stop)
00111 * 3. **MPC pin configuration** < This module
00112 * 4. GPIO direction configuration (PMR, PDR registers)
00113 * 5. Peripheral driver initialization
00114 *
00115 * @par Usage Example
00116 * @code{.c}
00117 * #include "rx_mpc.h"
00118 * #include "rx_port_constants.h"
00119 *
00120 * void hardware_init_pins(void)
00121 * {
00122 *     rx_err_t err;
00123 *
00124 *     // Configure motor PWM pins (GPTW channel 0)
00125 *     const rx_mpc_peripheral_config_t pwm_config = {
00126 *         .pin = k_port_e_pin_5, // PE5 = GPTW0A
00127 *         .psel = k_psel_gptw // GPTW function (0x1E)
00128 *     };
00129 *     err = rx_mpc_set_peripheral(&pwm_config);
00130 *     if (err != k_rx_ok) {
00131 *         // Handle error
00132 *     }
00133 *
00134 *     // Configure encoder pins (MTU phase counting)
00135 *     err = rx_mpc_set_mtu_encoder(k_port_2_pin_4); // P24 = MTCLKA
00136 *     err = rx_mpc_set_mtu_encoder(k_port_2_pin_5); // P25 = MTCLKB
00137 *
00138 *     // Configure debug UART (SCI9)
00139 *     err = rx_mpc_set_sci(k_port_b_pin_7); // PB7 = TXD9
00140 *     err = rx_mpc_set_sci(k_port_b_pin_6); // PB6 = RXD9
00141 *
00142 *     // Configure SPI communication (RSPI0)

00176 *
00177 * @par NASA Power of 10 Compliance
00178 * - **Rule 1**: [OK] No goto, setjmp, longjmp, or recursion
00179 * - **Rule 2**: [OK] All loops have fixed upper bounds (switch/case only)
00180 * - **Rule 3**: [OK] No dynamic memory allocation
00181 * - **Rule 4**: [OK] All functions < 60 lines
00182 * - **Rule 5**: [OK] Minimum 2 assertions per function (parameter validation)
00183 * - **Rule 6**: [OK] Variables declared at smallest scope
00184 * - **Rule 7**: [OK] All return values checked
00185 * - **Rule 8**: [OK] C23 typed enums for all constants, no magic numbers
00186 * - **Rule 9**: [WARN] Function pointers not used (simple direct calls)
00187 * - **Rule 10**: [OK] Compiles with -Wall -Wextra -Werror
00188 *
00189 * @par SOLID Principles
00190 * - **Single Responsibility**: MPC driver handles only pin mux configuration
00191 * - **Open/Closed**: New peripherals added via rx_mpc_set_peripheral() without
00192 *   modifying existing code
00193 * - **Interface Segregation**: Convenience functions (set_sci, set_rspi) separate
00194 *   from low-level set_peripheral()
00195 * - **Dependency Inversion**: Higher-level drivers depend on this abstraction,
00196 *   not on raw register writes
00197 *

00242 * Configuration Structures
00243 *
=====
*/
00244
00245 /**
00246 * @struct rx_mpc_peripheral_config_t
00247 * @brief MPC peripheral configuration structure for pin function assignment
00248 *
00249 * @details
00250 * This structure groups related parameters to prevent accidental parameter
00251 * swapping when calling rx_mpc_set_peripheral(). Using a struct provides:
00252 * - Type safety (compiler catches wrong parameter types)
00253 * - Named parameters (self-documenting code)

```

```

00255 * - Extensibility (can add fields without changing function signature)
00256 *
00257 * @par Memory Layout
00258 * | Offset | Size | Field | Type | Alignment |
00259 * |-----|-----|-----|-----|-----|
00260 * | 0 | 2 | pin | rx_port_pin_t (uint16_t) | 2 |
00261 * | 2 | 1 | psel | uint8_t | 1 |
00262 * | 3 | 1 | (padding) | - | - |
00263 * | **Total** | **4 bytes** | | | |
00264 *
00265 * @par Field Relationships
00266 * - `pin` determines which PFS register to modify
00267 * - `psel` determines what value to write to that register
00268 * - The (pin, psel) pair must be valid per RX72N hardware manual appendix
00269 *
00270 * @par Usage Example - Basic Configuration
00271 * @code{.c}
00272 * // Configure PE5 for GPTW0A (motor PWM output)
00273 * rx_mpc_peripheral_config_t pwm_config = {
00274 *     .pin = k_port_e_pin_5, // PE5
00275 *     .psel = k_psel_gptw // GPTW function select (0x1E)
00276 * };
00277 * rx_err_t err = rx_mpc_set_peripheral(&pwm_config);
00278 * @endcode
00279 *
00280 * @par Usage Example - Multiple Pins
00281 * @code{.c}
00282 * // Configure all SPI pins using array
00283 * const rx_mpc_peripheral_config_t spi_pins[] = {
00284 *     { .pin = k_port_a_pin_0, .psel = 0x0D }, // COPI
00285 *     { .pin = k_port_a_pin_1, .psel = 0x0D }, // CIPO
00286 *     { .pin = k_port_a_pin_3, .psel = 0x0D }, // CLK
00287 *     { .pin = k_port_a_pin_4, .psel = 0x0D }, // SSL0
00288 * };
00289 *
00290 * for (uint8_t i = 0; i < 4; i++) {
00291 *     rx_err_t err = rx_mpc_set_peripheral(&spi_pins[i]);
00292 *     if (err != k_rx_ok) {
00293 *         // Handle error
00294 *     }
00295 * }
00296 * @endcode
00297 *
00298 * @invariant pin must be a valid rx_port_pin_t value from rx_port_constants.h
00299 * @invariant psel must be in range [0, 31] (5-bit field)
00300 * @invariant (pin, psel) combination must be valid per hardware manual
00301 *
00302 * @see rx_mpc_set_peripheral() Function that uses this structure

Functions

- `rx_err_t rx_mtu_init_pwm` (`rx_mtu_channel_t` channel, `const rx_mtu_config_t *config`)
Initialize MTU channel for PWM output.
- `rx_err_t rx_mtu_set_duty` (`rx_mtu_channel_t` channel, `rx_mtu_output_t` output, `float duty_percent`)
Set PWM duty cycle.
- `rx_err_t rx_mtu_set_duty_raw` (`rx_mtu_channel_t` channel, `rx_mtu_output_t` output, `uint16_t duty_count`)
Set PWM duty cycle (raw count value).
- `rx_err_t rx_mtu_get_duty` (`rx_mtu_channel_t` channel, `rx_mtu_output_t` output, `float *duty_percent`)
Get current duty cycle.
- `rx_err_t rx_mtu_get_period` (`rx_mtu_channel_t` channel, `uint16_t *period_count`)
Get PWM period count.
- `rx_err_t rx_mtu_enable_output` (`rx_mtu_channel_t` channel, `rx_mtu_output_t` output, `bool enable`)
Enable or disable PWM output.
- `rx_err_t rx_mtu_start` (`rx_mtu_channel_t` channel)
Start MTU timer.
- `rx_err_t rx_mtu_stop` (`rx_mtu_channel_t` channel)
Stop MTU timer.
- `rx_err_t rx_mtu_deinit` (`rx_mtu_channel_t` channel)
Deinitialize MTU channel.

8.91.1 Detailed Description

MTU PWM Driver for RX72N Multi-Function Timer Unit.

Production-grade PWM driver for the RX72N Multi-Function Timer Unit (MTU3) peripheral. This module provides 16-bit PWM generation for motor control, quadrature encoder input, and general-purpose timing applications.

8.91.1.1 Purpose and Design Rationale

The MTU (Multi-Function Timer Unit) is a versatile timer peripheral that complements the GPTW module:

Feature	MTU3	GPTW
Counter Width	16-bit	32-bit
Channels	8 (MTU0-4, MTU6-7)	4 (GPTW0-3)
Outputs per Channel	Up to 4 (A/B/C/D)	2 (A/B)
Phase Counting	Yes (encoder input)	Limited
Complementary PWM	Yes (with deadtime)	Yes
Primary Use	Encoders, PWM	Motor PWM

STAR Project Usage:

- MTU1/MTU2: Quadrature encoder input (see `rx_mtu_encoder.h`)
- GPTW0-3: Motor PWM output (see [rx_gptw.h](#)) - recommended for motors

8.91.1.2 Key Features

PWM Generation:

- 8 timer channels with independent configuration
- PWM mode 1: Center-aligned (triangle wave) for symmetric current ripple
- PWM mode 2: Edge-aligned (sawtooth wave) for simple applications
- Complementary outputs with configurable deadtime
- Up to 4 outputs per channel (A/B/C/D) on some channels

Encoder Interface (MTU1/MTU2):

- Phase counting mode for quadrature encoders
- 16-bit pulse count with overflow detection
- See `rx_mtu_encoder.h` for encoder-specific functions

Timing Features:

- Input capture for pulse width measurement
- Output compare for waveform generation
- Cascade operation for extended range

8.91.1.3 Hardware Architecture

Register Base Addresses:

Channel	Base Address	Outputs	Notes
MTU0	0x000C1300	A,B,C,D	4 outputs
MTU1	0x000C1380	A,B	Encoder input
MTU2	0x000C1400	A,B	Encoder input
MTU3	0x000C1200	A,B,C,D	4 outputs, pairs with MTU4
MTU4	0x000C1201	A,B,C,D	4 outputs, pairs with MTU3
MTU6	0x000C1A00	A,B,C,D	4 outputs, pairs with MTU7
MTU7	0x000C1A01	A,B,C,D	4 outputs, pairs with MTU6

Note: MTU5 (U/V/W sub-channels at 0x000C1C80/90/A0) is not supported by this HAL.

Clock Configuration:

Parameter	Value	Notes
Clock Source	PCLKA	Peripheral Clock A
Clock Frequency	120 MHz	After system clock configuration
Counter Resolution	8.33 ns	1/120MHz
Max Period (16-bit)	546 us	65535 counts at 120 MHz
Min PWM Frequency	1831 Hz	1 / 546 us

8.91.1.4 PWM Modes

PWM Mode 1 (Center-Aligned):

- Counter counts up to period, then down to 0
- Symmetric current ripple (better for motors)
- Effective PWM frequency = $PCLKA / (2 \times \text{period})$

PWM Mode 2 (Edge-Aligned):

- Counter counts up to period, then resets
- Asymmetric ripple
- Effective PWM frequency = $PCLKA / \text{period}$

PWM Frequency Calculation:

For center-aligned (PWM mode 1):

$$f_{PWM} = \frac{f_{PCLKA}}{2 \times (TGRA + 1)}$$

For edge-aligned (PWM mode 2):

$$f_{PWM} = \frac{f_{PCLKA}}{TGRA + 1}$$

8.91.1.5 Performance Characteristics

Operation	Execution Time	Memory Usage	Notes
rx_mtu_init_pwm()	~50 us	0 heap	One-time setup
rx_mtu_set_duty()	~5 us	0	Float calculation
rx_mtu_set_duty_raw()	~1 us	0	Direct register write
rx_mtu_enable_output()	~1 us	0	Single register write

Memory Footprint:

- Static variables: ~32 bytes (initialization flags)
- Code size: ~1.5 KB (all functions)
- Stack usage: < 48 bytes (deepest call)
- Heap usage: 0 bytes (zero dynamic allocation)

Hardware Requirements:

Component	Requirement	Notes
MCU	Renesas RX72N	MTU3 peripheral required
Clock	PCLKA @ 120 MHz	System clock configuration
Power	3.3V I/O	LVC MOS compatible

Module Dependencies:

This module depends on:

- [rx_err.h](#) - Error code definitions
- [rx72n_mtu_regs.h](#) - MTU register definitions

This module is used by:

- [rx_mtu_encoder.c](#) - Encoder interface (MTU1/MTU2)
- Application code for auxiliary PWM outputs

NASA Power of 10 Compliance:

Rule	Status	Implementation
1. Simple control flow	↔ [OK]↔	No goto/setjmp/recursion
2. Fixed loop bounds	↔ [OK]↔	Loops bounded by channel count (8 max)
3. No dynamic allocation	↔ [OK]↔	Zero malloc/free, all static
4. Small functions	↔ [OK]↔	All functions < 60 lines
5. Assertions (>=2 per function)	↔ [OK]↔	Minimum 2 validation checks per function
6. Narrow scope	↔ [OK]↔	File-scope statics, minimal globals
7. Check return values	↔ [OK]↔	All functions return rx_err_t
8. Limited preprocessor	↔ [OK]↔	C23 typed enums, minimal macros
9. Pointer restrictions	↔ [OK]↔	Single-level pointers only

Rule	Status	Implementation
10. Compiler warnings	↔ [OK]↔	Compiles with -Wall -Wextra -Werror

SOLID Principles:

Single Responsibility (S):

- This module handles ONLY MTU PWM configuration
- Encoder functions are in rx_mtu_encoder.h

Open/Closed (O):

- Extensible via [rx_mtu_config_t](#) structure
- New modes can be added without modifying existing code

Liskov Substitution (L):

- All functions return rx_err_t with consistent semantics
- Channel and output parameters are validated uniformly

Interface Segregation (I):

- PWM functions separate from encoder functions
- Float and raw duty cycle APIs separate

Dependency Inversion (D):

- Depends on abstract error codes
- Can be mocked for unit testing

8.91.2.1 struct rx`mtu`config`t

MTU PWM Configuration Structure.

Contains all configuration parameters for initializing an MTU channel for PWM output. This structure is passed to `rx_mtu_init_pwm()` to configure the timer.

8.91.2.2 Configuration Guidelines

Frequency Limits (16-bit counter at 120 MHz):

- Maximum frequency: ~ 1.83 MHz (period = 65 counts)
- Minimum frequency: ~ 1831 Hz (period = 65535 counts)
- Recommended for motors: 15-25 kHz

Resolution Trade-off: Higher frequency $\rightarrow$ lower resolution (fewer counts per period)

- 20 kHz: 6000 counts $\rightarrow$ 0.017% resolution
- 100 kHz: 1200 counts $\rightarrow$ 0.083% resolution

Configuration Parameter Table:

Parameter	Min	Max	Default	Unit	Notes
frequency_hz	1831	1830000	20000	Hz	16-bit limit
deadtime_ns	0	65535	1000	ns	0 disables
enable_complementary	false	true	true	bool	A/B pairs
invert_polarity	false	true	false	bool	Active-low

Memory Layout:

Offset	Size	Field	Type	Alignment
0	4	frequency_hz	uint32_t	4
4	2	deadtime_ns	uint16_t	2
6	1	enable_complementary	bool	1

Offset	Size	Field	Type	Alignment
7	1	invert_polarity	bool	1
Total	8	-	-	4

Usage Example:

```
// Standard PWM configuration for auxiliary output
rx_mtu_config_t config = {
    .frequency_hz = 10000,           // 10 kHz
    .deadtime_ns = 500,             // 500 ns deadtime
    .enable_complementary = true,    // A/B complementary
    .invert_polarity = false        // Active-high
};

rx_err_t err = rx_mtu_init_pwm(k_mtu_channel_0, &config);
if (err != k_rx_ok) {
    rx_log_error("MTU", "Init failed: %d", err);
}
```

Invariant

frequency_hz must produce period ≤ 65535 counts
 Structure is copied during init (no need to keep alive)

Note

For motor control, prefer [rx_gptw.h](#) with 32-bit resolution

Warning

Invalid configurations rejected with k_rx_err_invalid_arg

See also

[rx_mtu_init_pwm\(\)](#) Channel initialization function
[rx_gptw_config_t](#) GPTW config (32-bit, recommended for motors)

Since

Version 1.0.0

Definition at line 404 of file [rx_mtu.h](#).

Collaboration diagram for rx_mtu_config_t:

Data Fields

uint16_t	deadtime_ns	Deadtime in nanoseconds. Deadtime inserted between complementary output transitions. Prevents shoot-through in H-bridge configurations. Set to 0 to disable deadtime insertion. Valid Range: [0, 65535 ns] Recommended: 500-1000 ns
bool	enable_complementary	Enable complementary outputs. When true, output pairs (A/B and C/D) are complementary: • Output B = inverted Output A (with deadtime) • Output D = inverted Output C (with deadtime) Required for H-bridge motor control applications.
uint32_t	frequency_hz	PWM frequency in Hz. Sets the PWM switching frequency. Limited by 16-bit counter: • Min: 1831 Hz (period = 65535 at 120 MHz) • Max: ~1.83 MHz (period = 65 at 120 MHz) Valid Range: [1831, 1830000 Hz] Recommended: 10000-20000 Hz for PWM applications
bool	invert_polarity	Invert PWM polarity. When true, inverts the PWM output polarity: • false: HIGH during duty cycle (active-high) • true: LOW during duty cycle (active-low)

8.91.3 Enumeration Type Documentation

8.91.3.1 rx_mtu_channel_t

```
enum rx_mtu_channel_t : uint8_t
```

MTU Channel Identifiers.

Identifies the MTU timer channels available on the RX72N. Note that MTU5 does not exist in this MCU family. Channels are grouped for specific functions:

8.91.3.2 Channel Groups and Functions

General Purpose PWM (MTU0, MTU3, MTU4, MTU6, MTU7):

- Up to 4 outputs per channel (A, B, C, D)
- Complementary PWM with deadtime
- MTU3+MTU4 and MTU6+MTU7 can be paired for synchronized operation

Encoder Input (MTU1, MTU2):

- Phase counting mode for quadrature encoders
- 16-bit pulse count with direction detection
- Used by rx_mtu_encoder.h for motor position feedback

Channel Specifications:

Channel	Base Address	Outputs	Phase Count	Paired With
MTU0	0x000C1300	A,B,C,D	No	-
MTU1	0x000C1380	A,B	Yes	MTU2
MTU2	0x000C1400	A,B	Yes	MTU1
MTU3	0x000C1200	A,B,C,D	No	MTU4
MTU4	0x000C1201	A,B,C,D	No	MTU3
MTU6	0x000C1A00	A,B,C,D	No	MTU7
MTU7	0x000C1A01	A,B,C,D	No	MTU6

STAR Project Usage:

Channel	Application	Configuration
MTU1	Encoder 0-1 (Motor 0, Motor 1)	Phase counting mode
MTU2	Encoder 2-3 (Motor 2, Motor 3)	Phase counting mode
MTU0,3,4,6,7	Available	General purpose PWM

Usage Example:

```
// Initialize MTU0 for PWM output
rx_mtu_config_t config = {
    .frequency_hz = 10000,
    .deadtime_ns = 500,
    .enable_complementary = true,
    .invert_polarity = false
};

rx_err_t err = rx_mtu_init_pwm(k_mtu_channel_0, &config);
if (err != k_rx_ok) {
    rx_log_error("MTU", "Init failed: %d", err);
}
```

Invariant

Channel 5 is not defined (MTU5 hardware exists but is not supported by this HAL)
 Channel values match hardware register offsets

Note

C23 typed enum with uint8_t underlying type
 Value 5 is intentionally skipped (MTU5 U/V/W sub-channels not supported by this HAL)

k_mtu_channel_7	MTU7: General purpose timer. 4 outputs (A,B,C,D). Base: 0x000C1A01. Pairs with MTU6

Definition at line 262 of file [rx_mtu.h](#).

```

00262         : uint8_t {
00263     k_mtu_channel_0 =
00264         0, /**< MTU0: General purpose timer. 4 outputs (A,B,C,D). Base: 0x000C1300. Standalone operation */
00265     k_mtu_channel_1 =
00266         1, /**< MTU1: Encoder input channel. 2 outputs (A,B). Base: 0x000C1380. Phase counting with MTU2 */
00267     k_mtu_channel_2 =
00268         2, /**< MTU2: Encoder input channel. 2 outputs (A,B). Base: 0x000C1400. Phase counting with MTU1 */
00269     k_mtu_channel_3 =
00270         3, /**< MTU3: General purpose timer. 4 outputs (A,B,C,D). Base: 0x000C1200. Pairs with MTU4 */
00271     k_mtu_channel_4 =
00272         4, /**< MTU4: General purpose timer. 4 outputs (A,B,C,D). Base: 0x000C1201. Pairs with MTU3 */
00273     k_mtu_channel_6 =
00274         6, /**< MTU6: General purpose timer. 4 outputs (A,B,C,D). Base: 0x000C1A00. Pairs with MTU7 */
00275     k_mtu_channel_7 =
00276         7, /**< MTU7: General purpose timer. 4 outputs (A,B,C,D). Base: 0x000C1A01. Pairs with MTU6 */
00277 } rx_mtu_channel_t;
```

8.91.3.3 rx_mtu_output_t

enum `rx_mtu_output_t` : `uint8_t`

MTU Output Channel Selection.

Selects which output pin to configure for PWM or compare match output. MTU channels can have 2 or 4 outputs depending on the channel.

8.91.3.4 Output Availability by Channel

Channel	Output A	Output B	Output C	Output D
MTU0	↔ [OK]↔	↔ [OK]↔	↔ [OK]↔	↔ [OK]↔
MTU1	↔ [OK]↔	↔ [OK]↔	-	-
MTU2	↔ [OK]↔	↔ [OK]↔	-	-
MTU3	↔ [OK]↔	↔ [OK]↔	↔ [OK]↔	↔ [OK]↔
MTU4	↔ [OK]↔	↔ [OK]↔	↔ [OK]↔	↔ [OK]↔
MTU6	↔ [OK]↔	↔ [OK]↔	↔ [OK]↔	↔ [OK]↔
MTU7	↔ [OK]↔	↔ [OK]↔	↔ [OK]↔	↔ [OK]↔

8.91.3.5 Complementary Pairs

When complementary output is enabled:

- A and B form a complementary pair
- C and D form a complementary pair (on channels with 4 outputs)
- Deadtime is inserted between transitions

Usage Example:

```
// Set 50% duty on output A of MTU0
rx_mtu_set_duty(k_mtu_channel_0, k_mtu_output_a, 50.0f);

// In complementary mode, output B is automatically inverted
// with deadtime inserted between transitions
```

Invariant

Output C and D only valid for channels with 4 outputs
 Output values are 0-3 (4 possible outputs)

Note

C23 typed enum with `uint8_t` underlying type

Warning

Using output C/D on MTU1/MTU2 will return `k_rx_err_invalid_arg`

```

8.91.4 Function Documentation

8.91.4.1 rx`mtu`deinit()

```

rx_err_t rx_mtu_deinit (
    const rx\_mtu\_channel\_t channel) [nodiscard]
```

Deinitialize MTU channel.

Stops timer, disables outputs, and releases resources.

Parameters

in	channel	MTU channel (0-4, 6-7)
----	---------	------------------------

Returns

`k_rx_ok` on success

`k_rx_err_invalid_arg` if channel is invalid

Deinitialize MTU channel.

Performs an orderly shutdown of the specified MTU channel:

1. Stop the timer counter ([rx_mtu_stop\(\)](#))
2. Disable all four outputs (A, B, C, D) via [rx_mtu_enable_output\(\)](#)
3. Clear the cached period to 0
4. Clear the initialized flag

After this call the channel may be safely re-initialized with different parameters via [rx_mtu_init_pwm\(\)](#).

Precondition

Motor or load driven by this channel must be stopped externally before call
channel must be a valid MTU channel (0-4, 6-7)

Postcondition

Timer stopped and outputs disabled
`s_mtu_initialized[channel] == false`
`s_mtu_period[channel] == k_mtu_period_zero`

Note

Not thread-safe: do not call while another task is accessing this channel
Idempotent with respect to re-initialization (can call init again after)

Warning

Ensure motor is at rest before calling to avoid abrupt stop

```
rx_err_t err = rx_mtu_deinit(k_mtu_channel_0);
```

See also

[rx_mtu_init_pwm\(\)](#) Re-initialize after deinit

Since

Version 1.0.0

Definition at line 1087 of file [rx_mtu.c](#).

```

01088 {
01089     if (!internal_is_valid_channel(channel)) {
01090         return k_rx_err_invalid_arg;
01091     }
01092
01093     /* Stop timer */
01094     rx_err_t err = rx_mtu_stop(channel);
01095     if (err != k_rx_ok) {
01096         return err;
01097     }
01098
01099     /* Disable all outputs */
01100     err = rx_mtu_enable_output(channel, k_mtu_output_a, false);
01101     if (err != k_rx_ok) {
01102         return err;
01103     }
01104     err = rx_mtu_enable_output(channel, k_mtu_output_b, false);
01105     if (err != k_rx_ok) {
01106         return err;
01107     }
01108     err = rx_mtu_enable_output(channel, k_mtu_output_c, false);
01109     if (err != k_rx_ok) {
01110         return err;
01111     }
01112     err = rx_mtu_enable_output(channel, k_mtu_output_d, false);
01113     if (err != k_rx_ok) {
01114         return err;
01115     }
01116
01117     /* Mark as uninitialized */
01118     s_mtu_initialized[channel] = false;
01119     s_mtu_period[channel] = k_mtu_period_zero;
01120
01121     rx_log_info(s_tag, "MTU channel deinitialized");
01122
01123     return k_rx_ok;
01124 }

```

References [internal_is_valid_channel\(\)](#), [k_mtu_output_a](#), [k_mtu_output_b](#), [k_mtu_output_c](#), [k_mtu_output_d](#), [k_mtu_period_zero](#), [rx_mtu_enable_output\(\)](#), [rx_mtu_stop\(\)](#), [s_mtu_initialized](#), [s_mtu_period](#), and [s_tag](#).

Here is the call graph for this function:

8.91.4.2 rx_mtu_enable_output()

```
rx_err_t rx_mtu_enable_output (
    const rx_mtu_channel_t channel,
    rx_mtu_output_t output,
    const bool enable)  [nodiscard]
```

Enable or disable PWM output.

Parameters

in	channel	MTU channel (0-4, 6-7)
in	output	Output channel (A/B/C/D)
in	enable	True to enable output, false to disable

Returns

k_rx_ok on success
k_rx_err_invalid_arg if channel or output is invalid
k_rx_err_invalid_state if channel not initialized

Enable or disable PWM output.

Controls whether the MTIOCA/B/C/D pin actively drives the PWM waveform or is held in its initial state (off). Modifies the TIORH or TIORL register nibble corresponding to the requested output without disturbing other outputs.

Output	Register	Nibble
A	TIORH	Low (bits 3:0)
B	TIORH	High (bits 7:4)
C	TIORL	Low (bits 3:0)
D	TIORL	High (bits 7:4)

Precondition

Channel must be initialized via [rx_mtu_init_pwm\(\)](#)
output must be a valid [rx_mtu_output_t](#) enum value

Postcondition

TIORH or TIORL nibble updated; timer continues running
Other outputs on the same channel are unchanged

Note

Not thread-safe: caller must prevent concurrent register access
Timer keeps running; only output pin drive changes

Warning

Outputs may remain HIGH when disabled, depending on last compare state

```
rx_mtu_enable_output(k_mtu_channel_0, k_mtu_output_a, false); // disable
```

Here is the call graph for this function:

Here is the caller graph for this function:

8.91.4.3 rx_mtu_get_duty()

```

rx_err_t rx_mtu_get_duty (
    const rx_mtu_channel_t channel,
    const rx_mtu_output_t output,
    float * duty_percent) [nodiscard]
  
```

Get current duty cycle.

Parameters

in	channel	MTU channel (0-4, 6-7)
in	output	Output channel (A/B/C/D)
out	duty_percent	Pointer to store duty cycle in percent

Returns

k_rx_ok on success
 k_rx_err_null_ptr if duty_percent is nullptr
 k_rx_err_invalid_arg if channel or output is invalid
 k_rx_err_invalid_state if channel not initialized

Get current duty cycle.

Reads the TGR register for the specified output and converts the raw count to a percentage using the cached period value.

$$\text{duty_percent} = \frac{\text{duty_count} \times 100}{\text{period}}$$

Precondition

Channel must be initialized via [rx_mtu_init_pwm\(\)](#)
 duty_percent must point to valid float storage

Postcondition

*duty_percent contains duty cycle in [0.0, 100.0] on success
 Hardware TGR register unchanged

Note

Not thread-safe: concurrent `set_duty` calls may cause torn reads

```
float duty;
rx_err_t err = rx_mtu_get_duty(k_mtu_channel_0, k_mtu_output_b, &duty);
```

```

References [internal_get_mtu_base\(\)](#), [internal_get_tgr_register\(\)](#), [k_mtu_duty_max](#), [s_mtu_initialized](#), [s_mtu_period](#), and [s_tag](#).

Here is the call graph for this function:

8.91.4.4 rx_mtu_get_period()

```
rx_err_t rx_mtu_get_period (
    const rx_mtu_channel_t channel,
    uint16_t * period_count)  [nodiscard]
```

Get PWM period count.

Returns the period register value (useful for raw duty cycle calculations).

Parameters

in	channel	MTU channel (0-4, 6-7)
out	period_count	Pointer to store period count

Returns

- k_rx_ok on success
- k_rx_err_null_ptr if period_count is nullptr
- k_rx_err_invalid_arg if channel is invalid
- k_rx_err_invalid_state if channel not initialized

Get PWM period count.

Returns the cached period value (TGRA) from initialization. Useful for calculating raw duty counts from percentages without floating-point.

Precondition

- Channel must be initialized via [rx_mtu_init_pwm\(\)](#)
- period_count must point to valid uint16_t storage

Postcondition

- *period_count contains the TGRA register value on success
- Hardware registers unchanged

Note

- Thread-safe: reads from static cache, no hardware access

```
uint16_t period;
rx_err_t err = rx_mtu_get_period(k_mtu_channel_0, &period);
if (err == k_rx_ok) {
    uint16_t half_duty = period / 2U; // 50%
    rx_mtu_set_duty_raw(k_mtu_channel_0, k_mtu_output_b, half_duty);
}
```

Here is the call graph for this function:

8.91.4.5 rx`mtu`init`pwm()

```
rx_err_t rx_mtu_init_pwm (
    const rx_mtu_channel_t channel,
    const rx_mtu_config_t * config) [nodiscard]
```

Initialize MTU channel for PWM output.

Configures MTU channel for PWM mode 1 (center-aligned, triangle wave). Enables timer and starts PWM generation at 0% duty cycle.

Parameters

in	channel	MTU channel (0-4, 6-7)
in	config	PWM configuration

Returns

k_rx_ok on success
 k_rx_err_invalid_arg if channel or config is invalid
 k_rx_err_invalid_state if MTU module not enabled

Initialize MTU channel for PWM output.

Configures an MTU channel for PWM Mode 1 (triangle wave, center-aligned) operation. Performs complete hardware setup including module clock enable, timer configuration, and automatic start.

8.91.4.6 Initialization Sequence

1. Validate config pointer
2. Get channel register base address
3. Calculate period from frequency
4. Enable MTU module clock (clear MSTPA bit)
5. Stop timer if running
6. Configure TCR (clock source, clear condition)
7. Configure TMDR (PWM Mode 1)
8. Configure TIORH/TIOLR (output behavior)
9. Set TGRA (period), clear TGRB/TGRC/TGRD (duty = 0)
10. Clear TCNT counter
11. Store period and set initialized flag
12. Start timer

8.91.4.7 PWM Mode 1 Configuration

Register	Value	Effect
TCR	TPSC=1, CCLR=TGRA	PCLKA/1, clear on TGRA match
TMDR	MD=PWM1	Triangle wave mode
TIORH/ L	Init low	Outputs toggle on compare match

Precondition

System clock configured (PCLKA = 120 MHz)
config pointer valid with valid frequency

Postcondition

MTU channel configured and timer running
All duty cycles initialized to 0%
s_mtu_initialized[channel] = true

Note

Timer starts automatically
Call once during system initialization

Warning

Not thread-safe: Configure before starting motor tasks

Example:

```
rx_mtu_config_t config = {
    .frequency_hz = 20000 // 20 kHz
};
rx_err_t err = rx_mtu_init_pwm(k_mtu_channel_0, &config);
```

Here is the call graph for this function:

8.91.4.8 rx_mtu_set_duty()

```

rx_err_t rx_mtu_set_duty (
    const rx_mtu_channel_t channel,
    rx_mtu_output_t output,
    const float duty_percent) [nodiscard]

```

Set PWM duty cycle.

Updates duty cycle for specified output channel. Change takes effect on next PWM period for glitch-free operation.

Parameters

in	channel	MTU channel (0-4, 6-7)
in	output	Output channel (A/B/C/D)
in	duty_percent	Duty cycle in percent (0.0 - 100.0)

Returns

`k_rx_ok` on success
`k_rx_err_invalid_arg` if channel, output, or duty is invalid
`k_rx_err_invalid_state` if channel not initialized

Set PWM duty cycle.

Converts a percentage value to raw timer counts using the cached period and writes it to the appropriate TGR register. The update is buffered and takes effect at the next PWM period boundary (glitch-free).

Algorithm:

1. Validate channel and initialization state
2. Validate `duty_percent` in range [0.0, 100.0]
3. Retrieve cached period from `s_mtu_period[channel]`
4. Compute `duty_count = (duty_percent * period) / 100`
5. Write `duty_count` to TGR register via [internal_set_duty_raw_mtu\(\)](#)

Precondition

Channel must be initialized via [rx_mtu_init_pwm\(\)](#)
`duty_percent` must be in [0.0, 100.0]

Postcondition

TGR register updated with new duty count
Change takes effect at next PWM period boundary

Note

Not thread-safe: caller must prevent concurrent access

```
rx_err_t err = rx_mtu_set_duty(k_mtu_channel_0, k_mtu_output_b, 50.0f);
```

00677         rx_log_error(s_tag, "Invalid duty cycle");
00678         return k_rx_err_invalid_arg;
00679     }
00680     /* Convert percentage to count value */
00681     const uint16_t period = s_mtu_period[channel];
00682     const uint16_t duty_count = (uint16_t)((duty_percent * period) / (float)k_mtu_duty_divisor);
00683     return internal_set_duty_raw_mtu(mtu, output, duty_count);
00684 }

```

References [internal_get_mtu_base\(\)](#), [internal_set_duty_raw_mtu\(\)](#), [k_mtu_duty_divisor](#), [k_mtu_duty_max](#), [k_mtu_duty_min](#), [s_mtu_initialized](#), [s_mtu_period](#), and [s_tag](#).

Here is the call graph for this function:

8.91.4.9 rx_mtu_set_duty_raw()

```

rx_err_t rx_mtu_set_duty_raw (
    const rx_mtu_channel_t channel,
    rx_mtu_output_t output,
    uint16_t duty_count) [nodiscard]

```

Set PWM duty cycle (raw count value).

Updates duty cycle using raw counter value for efficiency. Useful in tight control loops where floating-point calculation overhead should be avoided.

Parameters

in	channel	MTU channel (0-4, 6-7)
in	output	Output channel (A/B/C/D)
in	duty_count	Duty cycle count (0 - period_count)

Returns

[k_rx_ok](#) on success
[k_rx_err_invalid_arg](#) if channel, output, or count is invalid
[k_rx_err_invalid_state](#) if channel not initialized

Set PWM duty cycle (raw count value).

Directly sets the compare register (TGR) for the specified output to `duty_count` timer ticks. Values larger than the channel period are clamped to the period value (100% duty). The update is buffered.

Use this function when the caller has already converted a duty percentage to counts (e.g. via [rx_mtu_get_period\(\)](#)) to avoid redundant floating-point multiplication.

Precondition

Channel must be initialized via [rx_mtu_init_pwm\(\)](#)
`duty_count` should be in `[0, period]`; values above period are clamped

Postcondition

TGR register written with (possibly clamped) `duty_count`
 Change takes effect at next PWM period boundary

Note

Not thread-safe: caller must prevent concurrent access

```
uint16_t period;
rx_mtu_get_period(k_mtu_channel_0, &period);
rx_mtu_set_duty_raw(k_mtu_channel_0, k_mtu_output_b, period / 2U); // 50%
```

8.91.4.10 rx'mtu'start()

```
rx_err_t rx_mtu_start (
    const rx_mtu_channel_t channel) [nodiscard]
```

Start MTU timer.

Starts the timer counter for PWM generation. Timer is automatically started during init, but can be stopped/restarted.

Parameters

in	channel	MTU channel (0-4, 6-7)
----	---------	------------------------

Returns

k_rx_ok on success
k_rx_err_invalid_arg if channel is invalid

Start MTU timer.

Sets the Count Start (CSTn) bit in the appropriate TSTR register to begin counter operation. Channels 0-4 use TSTRA, channels 6-7 use TSTRB.

8.91.4.11 TSTR Bit Mapping

Channel	Register	Bit
MTU0	TSTRA	CST0
MTU1	TSTRA	CST1
MTU2	TSTRA	CST2
MTU3	TSTRA	CST3
MTU4	TSTRA	CST4
MTU6	TSTRB	CST6
MTU7	TSTRB	CST7

Precondition

Channel initialized via [rx_mtu_init_pwm\(\)](#)

Postcondition

Timer counting, PWM output active

Note

Timer automatically started during init

Idempotent: Safe to call when already running

8.91.4.12 rx_mtu_stop()

```
rx_err_t rx_mtu_stop (
    const rx_mtu_channel_t channel) [nodiscard]
```

Stop MTU timer.

Stops the timer counter. PWM outputs will hold their last state.

Parameters

in	channel	MTU channel (0-4, 6-7)
----	---------	------------------------

Returns

k_rx_ok on success

k_rx_err_invalid_arg if channel is invalid

Stop MTU timer.

Clears the Count Start (CSTn) bit in the appropriate TSTR register to halt counter operation. Counter value and output state are preserved.

Precondition

None (can be called on uninitialized channel)

Postcondition

Timer stopped, counter preserved

Output pins hold current state

Note

Does NOT check initialization flag (safe for use during init)

Idempotent: Safe to call when already stopped

Warning

Outputs may remain HIGH - disable outputs for safe state

See also

00002  * @file rx_mtu.h
00003  * @brief MTU PWM Driver for RX72N Multi-Function Timer Unit
00004  *
00005  * @details
00006  * **Production-grade PWM driver** for the RX72N Multi-Function Timer Unit (MTU3)
00007  * peripheral. This module provides 16-bit PWM generation for motor control,
00008  * quadrature encoder input, and general-purpose timing applications.
00009  *
00010  * ## Purpose and Design Rationale
00011  *
00012  * The MTU (Multi-Function Timer Unit) is a versatile timer peripheral that
00013  * complements the GPTW module:
00014  *
00015  * | Feature | MTU3 | GPTW |
00016  * |-----|-----|-----|
00017  * | Counter Width | 16-bit | 32-bit |
00018  * | Channels | 8 (MTU0-4, MTU6-7) | 4 (GPTW0-3) |
00019  * | Outputs per Channel | Up to 4 (A/B/C/D) | 2 (A/B) |
00020  * | Phase Counting | Yes (encoder input) | Limited |
00021  * | Complementary PWM | Yes (with deadtime) | Yes |
00022  * | Primary Use | Encoders, PWM | Motor PWM |
00023  *
00024  * **STAR Project Usage**:
00025  * - MTU1/MTU2: Quadrature encoder input (see rx_mtu_encoder.h)
00026  * - GPTW0-3: Motor PWM output (see rx_gptw.h) - **recommended for motors**
00027  *
00028  * ## Key Features
00029  *
00030  * **PWM Generation**:
00031  * - 8 timer channels with independent configuration
00032  * - PWM mode 1: Center-aligned (triangle wave) for symmetric current ripple
00033  * - PWM mode 2: Edge-aligned (sawtooth wave) for simple applications
00034  * - Complementary outputs with configurable deadtime
00035  * - Up to 4 outputs per channel (A/B/C/D) on some channels
00036  *
00037  * **Encoder Interface** (MTU1/MTU2):
00038  * - Phase counting mode for quadrature encoders
00039  * - 16-bit pulse count with overflow detection
00040  * - See rx_mtu_encoder.h for encoder-specific functions
00041  *
00042  * **Timing Features**:
00043  * - Input capture for pulse width measurement
00044  * - Output compare for waveform generation
00045  * - Cascade operation for extended range
00046  *
00047  * ## Hardware Architecture
00048  *

```

```

00049 * @par Register Base Addresses:
00050 *
00051 * | Channel | Base Address | Outputs | Notes |
00052 * |-----|-----|-----|-----|
00053 * | MTU0 | 0x000C1300 | A,B,C,D | 4 outputs |
00054 * | MTU1 | 0x000C1380 | A,B | Encoder input |
00055 * | MTU2 | 0x000C1400 | A,B | Encoder input |
00056 * | MTU3 | 0x000C1200 | A,B,C,D | 4 outputs, pairs with MTU4 |
00057 * | MTU4 | 0x000C1201 | A,B,C,D | 4 outputs, pairs with MTU3 |
00058 * | MTU6 | 0x000C1A00 | A,B,C,D | 4 outputs, pairs with MTU7 |
00059 * | MTU7 | 0x000C1A01 | A,B,C,D | 4 outputs, pairs with MTU6 |
00060 *
00061 * Note: MTU5 (U/V/W sub-channels at 0x000C1C80/90/A0) is not supported by this HAL.
00062 *
00063 * @par Clock Configuration:
00064 *
00065 * | Parameter | Value | Notes |
00066 * |-----|-----|-----|
00067 * | Clock Source | PCLKA | Peripheral Clock A |
00068 * | Clock Frequency | 120 MHz | After system clock configuration |
00069 * | Counter Resolution | 8.33 ns | 1/120MHz |
00070 * | Max Period (16-bit) | 546 us | 65535 counts at 120 MHz |
00071 * | Min PWM Frequency | 1831 Hz | 1 / 546 us |
00072 *
00073 * ## PWM Modes
00074 *
00075 * **PWM Mode 1 (Center-Aligned)**:
00076 * - Counter counts up to period, then down to 0
00077 * - Symmetric current ripple (better for motors)
00078 * - Effective PWM frequency = PCLKA / (2 x period)
00079 *
00080 * **PWM Mode 2 (Edge-Aligned)**:
00081 * - Counter counts up to period, then resets
00082 * - Asymmetric ripple
00083 * - Effective PWM frequency = PCLKA / period
00084 *
00085 * @par PWM Frequency Calculation:
00086 *
00087 * For center-aligned (PWM mode 1):
00088 * @f[
00089 *  $f_{\text{PWM}} = \frac{f_{\text{PCLKA}}}{2 \times (\text{TGRA} + 1)}$ 
00090 * @f]
00091 *
00092 * For edge-aligned (PWM mode 2):
00093 * @f[
00094 *  $f_{\text{PWM}} = \frac{f_{\text{PCLKA}}}{\text{TGRA} + 1}$ 
00095 * @f]
00096 *
00097 * ## Performance Characteristics
00098 *
00099 * | Operation | Execution Time | Memory Usage | Notes |
00100 * |-----|-----|-----|-----|
00101 * | rx_mtu_init_pwm() | ~50 us | 0 heap | One-time setup |
00102 * | rx_mtu_set_duty() | ~5 us | 0 | Float calculation |
00103 * | rx_mtu_set_duty_raw() | ~1 us | 0 | Direct register write |
00104 * | rx_mtu_enable_output() | ~1 us | 0 | Single register write |
00105 *
00106 * **Memory Footprint**:
00107 * - Static variables: ~32 bytes (initialization flags)
00108 * - Code size: ~1.5 KB (all functions)
00109 * - Stack usage: < 48 bytes (deepest call)
00110 * - Heap usage: 0 bytes (zero dynamic allocation)
00111 *
00112 * @par Hardware Requirements:
00113 *
00114 * | Component | Requirement | Notes |
00115 * |-----|-----|-----|
00116 * | MCU | Renesas RX72N | MTU3 peripheral required |
00117 * | Clock | PCLKA @ 120 MHz | System clock configuration |
00118 * | Power | 3.3V I/O | LVCMOS compatible |
00119 *
00120 * @par Module Dependencies:
00121 *
00122 * **This module depends on**:
00123 * - `rx_err.h` - Error code definitions
00124 * - `rx72n_mtu_regs.h` - MTU register definitions
00125 *
00126 * **This module is used by**:
00127 * - `rx_mtu_encoder.c` - Encoder interface (MTU1/MTU2)
00128 * - Application code for auxiliary PWM outputs
00129 *
00130 * @par NASA Power of 10 Compliance:
00131 *
00132 * | Rule | Status | Implementation |
00133 * |-----|-----|-----|
00134 * | 1. Simple control flow | [OK] | No goto/setjmp/recursion |
00135 * | 2. Fixed loop bounds | [OK] | Loops bounded by channel count (8 max) |

```

```

00136 * | 3. No dynamic allocation | [OK] | Zero malloc/free, all static |
00137 * | 4. Small functions | [OK] | All functions < 60 lines |
00138 * | 5. Assertions (>=2 per function) | [OK] | Minimum 2 validation checks per function |
00139 * | 6. Narrow scope | [OK] | File-scope statics, minimal globals |
00140 * | 7. Check return values | [OK] | All functions return rx_err_t |
00141 * | 8. Limited preprocessor | [OK] | C23 typed enums, minimal macros |
00142 * | 9. Pointer restrictions | [OK] | Single-level pointers only |
00143 * | 10. Compiler warnings | [OK] | Compiles with -Wall -Wextra -Werror |
00144 *
00145 * @par SOLID Principles:
00146 *
00147 * **Single Responsibility (S)**:
00148 * - This module handles ONLY MTU PWM configuration
00149 * - Encoder functions are in rx_mtu_encoder.h
00150 *
00151 * **Open/Closed (O)**:
00152 * - Extensible via rx_mtu_config_t structure
00153 * - New modes can be added without modifying existing code
00154 *
00155 * **Liskov Substitution (L)**:
00156 * - All functions return rx_err_t with consistent semantics
00157 * - Channel and output parameters are validated uniformly
00158 *
00159 * **Interface Segregation (I)**:
00160 * - PWM functions separate from encoder functions
00161 * - Float and raw duty cycle APIs separate
00162 *
00163 * **Dependency Inversion (D)**:
00164 * - Depends on abstract error codes
00165 * - Can be mocked for unit testing
00166 *
00167 * @see rx_gptw.h GPTW driver (preferred for motor PWM)
00168 * @see rx_mtu_encoder.h Encoder interface using MTU phase counting
00169 * @see rx72n_mtu_regs.h Register definitions
00170 * @see RX72N Hardware Manual Section 24 - Multi-Function Timer Unit 3

00196 * @enum rx_mtu_channel_t
00197 * @brief MTU Channel Identifiers
00198 *
00199 * @details
00200 * Identifies the MTU timer channels available on the RX72N. Note that MTU5
00201 * does not exist in this MCU family. Channels are grouped for specific functions:
00202 *
00203 * ## Channel Groups and Functions
00204 *
00205 * **General Purpose PWM** (MTU0, MTU3, MTU4, MTU6, MTU7):
00206 * - Up to 4 outputs per channel (A, B, C, D)
00207 * - Complementary PWM with deadline
00208 * - MTU3+MTU4 and MTU6+MTU7 can be paired for synchronized operation
00209 *
00210 * **Encoder Input** (MTU1, MTU2):
00211 * - Phase counting mode for quadrature encoders
00212 * - 16-bit pulse count with direction detection
00213 * - Used by rx_mtu_encoder.h for motor position feedback
00214 *
00215 * @par Channel Specifications:
00216 *
00217 * | Channel | Base Address | Outputs | Phase Count | Paired With |
00218 * |-----|-----|-----|-----|-----|
00219 * | MTU0 | 0x000C1300 | A,B,C,D | No | - |
00220 * | MTU1 | 0x000C1380 | A,B | Yes | MTU2 |

```

```

00221 * | MTU2 | 0x000C1400 | A,B | Yes | MTU1 |
00222 * | MTU3 | 0x000C1200 | A,B,C,D | No | MTU4 |
00223 * | MTU4 | 0x000C1201 | A,B,C,D | No | MTU3 |
00224 * | MTU6 | 0x000C1A00 | A,B,C,D | No | MTU7 |
00225 * | MTU7 | 0x000C1A01 | A,B,C,D | No | MTU6 |
00226 *
00227 * @par STAR Project Usage:
00228 *
00229 * | Channel | Application | Configuration |
00230 * |-----|-----|-----|
00231 * | MTU1 | Encoder 0-1 (Motor 0, Motor 1) | Phase counting mode |
00232 * | MTU2 | Encoder 2-3 (Motor 2, Motor 3) | Phase counting mode |
00233 * | MTU0,3,4,6,7 | Available | General purpose PWM |
00234 *
00235 * @par Usage Example:
00236 * @code{.c}
00237 * // Initialize MTU0 for PWM output
00238 * rx_mtu_config_t config = {
00239 *     .frequency_hz = 10000,
00240 *     .deadtime_ns = 500,
00241 *     .enable_complementary = true,
00242 *     .invert_polarity = false
00243 * };
00244 *
00245 * rx_err_t err = rx_mtu_init_pwm(k_mtu_channel_0, &config);
00246 * if (err != k_rx_ok) {
00247 *     rx_log_error("MTU", "Init failed: %d", err);
00248 * }
00249 * @endcode
00250 *
00251 * @invariant Channel 5 is not defined (MTU5 hardware exists but is not supported by this HAL)
00252 * @invariant Channel values match hardware register offsets
00253 *
00254 * @note C23 typed enum with uint8_t underlying type
00255 * @note Value 5 is intentionally skipped (MTU5 U/V/W sub-channels not supported by this HAL)
00256 *
00257 * @see rx_mtu_encoder.h Encoder functions using MTU1/MTU2
00258 * @see RX72N Hardware Manual Section 24 - MTU3 channels
00259 *
00260 * @since Version 1.0.0
00261 */

00275     k_mtu_channel_7 =
00276         7, /**< MTU7: General purpose timer. 4 outputs (A,B,C,D). Base: 0x000C1A01. Pairs with MTU6 */
00277 } rx_mtu_channel_t;
00278
00279 /**
00280 * @enum rx_mtu_output_t
00281 * @brief MTU Output Channel Selection
00282 *
00283 * @details
00284 * Selects which output pin to configure for PWM or compare match output.
00285 * MTU channels can have 2 or 4 outputs depending on the channel.
00286 *
00287 * ## Output Availability by Channel
00288 *
00289 * | Channel | Output A | Output B | Output C | Output D |
00290 * |-----|-----|-----|-----|-----|
00291 * | MTU0 | [OK] | [OK] | [OK] | [OK] |
00292 * | MTU1 | [OK] | [OK] | - | - |
00293 * | MTU2 | [OK] | [OK] | - | - |
00294 * | MTU3 | [OK] | [OK] | [OK] | [OK] |
00295 * | MTU4 | [OK] | [OK] | [OK] | [OK] |
00296 * | MTU6 | [OK] | [OK] | [OK] | [OK] |
00297 * | MTU7 | [OK] | [OK] | [OK] | [OK] |
00298 *
00299 * ## Complementary Pairs
00300 *
00301 * When complementary output is enabled:
00302 * - A and B form a complementary pair
00303 * - C and D form a complementary pair (on channels with 4 outputs)
00304 * - Deadtime is inserted between transitions
00305 *
00306 * @par Usage Example:
00307 * @code{.c}

```

```

00308 * // Set 50% duty on output A of MTU0
00309 * rx_mtu_set_duty(k_mtu_channel_0, k_mtu_output_a, 50.0f);
00310 *
00311 * // In complementary mode, output B is automatically inverted
00312 * // with deadtime inserted between transitions
00313 * @endcode
00314 *
00315 * @invariant Output C and D only valid for channels with 4 outputs
00316 * @invariant Output values are 0-3 (4 possible outputs)
00317 *
00318 * @note C23 typed enum with uint8_t underlying type
00319 * @warning Using output C/D on MTU1/MTU2 will return k_rx_err_invalid_arg
00320 *
00321 * @see rx_mtu_channel_t Channel selection
00322 * @see rx_mtu_set_duty() Set duty cycle on specific output
00323 *
00324 * @since Version 1.0.0
00325 */
00326 typedef enum : uint8_t {
00327     k_mtu_output_a =
00328         0, /**< MTIOCA output pin. Available on all channels. Compare register: TGRA. Primary PWM output */
00329     k_mtu_output_b =
00330         1, /**< MTIOCB output pin. Available on all channels. Compare register: TGRB. Complementary to A when enabled */

00338 * @struct rx_mtu_config_t
00339 * @brief MTU PWM Configuration Structure
00340 *
00341 * @details
00342 * Contains all configuration parameters for initializing an MTU channel
00343 * for PWM output. This structure is passed to rx_mtu_init_pwm() to
00344 * configure the timer.
00345 *
00346 * ## Configuration Guidelines
00347 *
00348 * **Frequency Limits** (16-bit counter at 120 MHz):
00349 * - Maximum frequency: ~1.83 MHz (period = 65 counts)
00350 * - Minimum frequency: ~1831 Hz (period = 65535 counts)
00351 * - Recommended for motors: 15-25 kHz
00352 *
00353 * **Resolution Trade-off**:
00354 * Higher frequency -> lower resolution (fewer counts per period)
00355 * - 20 kHz: 6000 counts -> 0.017% resolution
00356 * - 100 kHz: 1200 counts -> 0.083% resolution
00357 *
00358 * @par Configuration Parameter Table:
00359 *
00360 * | Parameter | Min | Max | Default | Unit | Notes |
00361 * |-----|-----|-----|-----|-----|-----|
00362 * | frequency_hz | 1831 | 1830000 | 20000 | Hz | 16-bit limit |
00363 * | deadtime_ns | 0 | 65535 | 1000 | ns | 0 disables |
00364 * | enable_complementary | false | true | true | bool | A/B pairs |
00365 * | invert_polarity | false | true | false | bool | Active-low |
00366 *
00367 * @par Memory Layout:
00368 *
00369 * | Offset | Size | Field | Type | Alignment |
00370 * |-----|-----|-----|-----|-----|
00371 * | 0 | 4 | frequency_hz | uint32_t | 4 |
00372 * | 4 | 2 | deadtime_ns | uint16_t | 2 |
00373 * | 6 | 1 | enable_complementary | bool | 1 |
00374 * | 7 | 1 | invert_polarity | bool | 1 |
00375 * | **Total** | **8** | - | - | **4** |
00376 *
00377 * @par Usage Example:
00378 * @code{.c}
00379 * // Standard PWM configuration for auxiliary output
00380 * rx_mtu_config_t config = {
00381 *     .frequency_hz = 10000, // 10 kHz
00382 *     .deadtime_ns = 500, // 500 ns deadtime
00383 *     .enable_complementary = true, // A/B complementary
00384 *     .invert_polarity = false // Active-high
00385 * };
00386 *

POEG Motor Fault Protection Driver API.

```
#include <stdint.h>
```

```
#include "rx_err.h"
```

Include dependency graph for rx_poeg.h:

This graph shows which files directly or indirectly include this file:

Enumerations

- enum `rx_poeg_motor_count_t` : `uint8_t` { `k_poeg_motor_count` = 4 }
Number of motors with POEG fault protection.
- enum `rx_poeg_isr_priority_t` : `uint8_t` { `k_poeg_isr_priority` = 14 }
ICU priority for POEG fault interrupts.

Functions

- `rx_err_t rx_poeg_init` (void)
Initialize POEG fault protection for all 4 motor channels.
- `rx_err_t rx_poeg_get_fault_status` (`uint8_t` motor_index, `bool *fault_active`)
Check if a motor has an active POEG fault.
- `rx_err_t rx_poeg_clear_fault` (`uint8_t` motor_index)
Clear POEG fault and re-enable motor output.
- `rx_err_t rx_poeg_software_stop` (`uint8_t` motor_index)
Trigger software emergency stop on a specific motor.
- `rx_err_t rx_poeg_clear_software_stop` (`uint8_t` motor_index)
Release software emergency stop on a specific motor.

8.93.1 Detailed Description

POEG Motor Fault Protection Driver API.

Provides hardware-level emergency PWM output disable via the POEG module. When a DRV8263H motor driver asserts its nFAULT output (active low), the corresponding GTETRGR pin triggers POEG to immediately disable GPTW PWM outputs, placing the H-bridge in a safe Hi-Z state.

System Architecture

```

* DRV8263H nFAULT (active low)
*   |
*   v
* GTETRGR pin --> POEG (PIDF flag) --> GPTW output disable (Hi-Z)
*   |                               |
*   v                               v
* ICU interrupt --> ISR --> shared_data fault flags
*

```

Motor-to-POEG Group Mapping

Motor	nFAULT Pin	GTETRGR	POEG Group	Vector
0	P15	A	A	188
1	PA6	B	B	189
2	PC4	C	C	190
3	P14	D	D	191

Two-Layer Protection

1. Hardware (automatic): POEG disables GPTW outputs within nanoseconds of nFAULT assertion. No firmware intervention required for the stop.
2. Firmware (ISR): POEG interrupt logs fault, sets `shared_data` flags, and prevents motor re-enable until fault is resolved.

8.93.2 Enumeration Type Documentation

8.93.2.1 `rx_poeg_isr_priority_t`

enum [rx_poeg_isr_priority_t](#) : `uint8_t`

ICU priority for POEG fault interrupts.

Priority 14 (near-maximum) ensures motor faults are handled immediately. Only NMI (level 15) has higher priority.

Since

Version 1.0.0

Enumerator

k_poeg_isr_priority	High priority for safety-critical fault ISR
---------------------	---

Definition at line 81 of file [rx_poeg.h](#).

```
00081      : uint8_t {
00082  k_poeg_isr_priority = 14, /**< High priority for safety-critical fault ISR */
00083 } rx_poeg_isr_priority_t;
```

8.93.2.2 rx_poeg_motor_count_t

```
enum rx_poeg_motor_count_t : uint8_t
```

Number of motors with POEG fault protection.

Since

Version 1.0.0

Enumerator

k_poeg_motor_count	4 motors, one POEG group each (A-D)
--------------------	-------------------------------------

Definition at line 67 of file [rx_poeg.h](#).

```
00067      : uint8_t {
00068  k_poeg_motor_count = 4, /**< 4 motors, one POEG group each (A-D) */
00069 } rx_poeg_motor_count_t;
```

8.93.3 Function Documentation

8.93.3.1 rx_poeg_clear_fault()

```
rx_err_t rx_poeg_clear_fault (
    uint8_t motor_index)
```

Clear POEG fault and re-enable motor output.

Attempts to clear the PIDF flag for the specified motor's POEG group. The flag can only be cleared when the underlying fault condition has been resolved (i.e., DRV8263H nFAULT deasserted / GTETRQ pin high).

After clearing, GPTW output re-enables at the end of the next GPTW counting cycle (delay of up to 1 PWM period, typically 50us at 20kHz).

Parameters

in	motor_index	Motor index (0-3)
----	-------------	-------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Fault cleared successfully
k_rx_err_invalid_arg	motor_index >= 4
k_rx_err_busy	Fault condition still active (nFAULT still asserted)

Precondition

Underlying fault resolved (DRV8263H nFAULT deasserted)

Postcondition

If successful, PIDF flag cleared and GPTW output will re-enable
shared_data fault_flags[motor_index] cleared

Warning

Returns k_rx_err_busy if fault source is still active

Note

Motor control task should verify estop is cleared before resuming PWM

Since

Version 1.0.0

Clear POEG fault and re-enable motor output.

Reads POEGGn, masks off the PIDF / IOCF / OSTPF latched-fault bits, and writes the result back. Refuses to clear (returns k_rx_err_busy) while the underlying nFAULT pin is still active (POEGGn.ST==0 indicates nFAULT still asserted under INV=1). After a successful clear, also clears any driver-fault E-Stop in shared_data when applicable, so the system can resume motor control if the underlying physical fault has been cleared.

Note

Not thread-safe with concurrent access to shared_data E-Stop fields. Typically called from the safety supervisor task.

Definition at line 327 of file rx_poeg.c.

```
00328 {
00329     if (motor_index >= k_poeg_motor_count) {
00330         return k_rx_err_invalid_arg;
00331     }
00332
00333     volatile rx_poegg_regs_t* poeg = s_poeg_groups[motor_index];
00334
00335     /* Check if fault source is still active (ST bit shows pin state) */
00336     /* With INV=1, ST=0 means nFAULT is still asserted (fault active) */
```

```

00337 if ((poeg->poeggn & k_poeg_st_high) == 0) {
00338     rx_log_warn_val(s_tag, "Cannot clear: nFAULT still active motor", (uint32_t)motor_index);
00339     return k_rx_err_busy;
00340 }
00341
00342 /* Clear PIDF and IOCF flags by writing 0 to them */
00343 uint32_t reg_val = poeg->poeggn;
00344 reg_val &= ~(k_poeg_pidf_detected | k_poeg_iocf_detected | k_poeg_ostpf_detected);
00345 poeg->poeggn = reg_val;
00346
00347 /* Clear e-stop if this was the cause */
00348 if (shared_data_get_estop_reason() == k_estop_reason_driver_fault) {
00349     (void)shared_data_clear_estop();
00350 }
00351
00352 rx_log_info_val(s_tag, "Fault cleared motor", (uint32_t)motor_index);
00353 return k_rx_ok;
00354 }

```

8.93.3.2 rx_poeg_clear_software_stop()

```

rx_err_t rx_poeg_clear_software_stop (
    uint8_t motor_index)

```

Release software emergency stop on a specific motor.

Clears the SSF (Software Stop Flag) in the POEGGn register. GPTW output re-enables at end of next counting cycle if no other fault flags (PIDF, IOCF, OSTPF) are active.

Parameters

in	motor_index	Motor index (0-3)
----	-------------	-------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Software stop released
k_rx_err_invalid_arg	motor_index >= 4

Postcondition

SSF flag cleared in POEGGn register

See also

[rx_poeg_software_stop\(\)](#) Activate software stop

Since

Version 1.0.0

Release software emergency stop on a specific motor.

Reads POEGGn, clears the SSF bit, and writes the result back. This re-enables the GPTW outputs of the targeted motor (subject to any hardware-latched fault flags still being cleared first).

Note

Safe from any context including ISR; single read-modify-write.

Definition at line 388 of file [rx_poeg.c](#).

```
00389 {
00390     if (motor_index >= k_poeg_motor_count) {
00391         return k_rx_err_invalid_arg;
00392     }
00393
00394     uint32_t reg_val = s_poeg_groups[motor_index]->poeggn;
00395     reg_val &= ~k_poeg_ssf_stop;
00396     s_poeg_groups[motor_index]->poeggn = reg_val;
00397     return k_rx_ok;
00398 }
```

References [k_poeg_motor_count](#), [k_poeg_ssf_stop](#), and [s_poeg_groups](#).

8.93.3.3 rx_poeg_get_fault_status()

```
rx_err_t rx_poeg_get_fault_status (
    uint8_t motor_index,
    bool * fault_active)
```

Check if a motor has an active POEG fault.

Reads the POEGGn register for the specified motor's POEG group and returns whether the PIDF (port input detection flag) is set.

Parameters

in	motor_index	Motor index (0-3)
out	fault_active	true if POEG fault is active

Returns

rx_err_t Error code

Return values

k_rx_ok	Status read successfully
k_rx_err_null_ptr	fault_active is nullptr
k_rx_err_invalid_arg	motor_index >= 4

Precondition

POEG initialized via [rx_poeg_init\(\)](#)

Postcondition

No side effects on hardware state

Note

Thread Safety: Safe to call from any context (read-only register access)

Since

Version 1.0.0

Check if a motor has an active POEG fault.

Reads POEGn for the specified motor's POEG group and checks the OR of the three fault-source bits: PIDF (port input fault), IOCF (output comparator fault), and OSTPF (over-stop signal fault). Reports whether any of them are currently latched.

Note

Safe from any context including ISR; single register read.

Definition at line 297 of file [rx_poeg.c](#).

```
00298 {
00299   RX_CHECK_NULL_PTR(fault_active, s_tag, "fault_active is nullptr");
00300
00301   if (motor_index >= k_poeg_motor_count) {

00303   }
00304
00305   const uint32_t status = s_poeg_groups[motor_index]->poeggn;
00306   *fault_active =
00307       ((status & (k_poeg_pidf_detected | k_poeg_iocf_detected | k_poeg_ostpf_detected)) != 0);
00308
00309   return k_rx_ok;
00310 }
```

References [k_poeg_iocf_detected](#), [k_poeg_motor_count](#), [k_poeg_ostpf_detected](#), [k_poeg_pidf_detected](#), [s_poeg_groups](#), and [s_tag](#).

8.93.3.4 rx_poeg_init()

```
rx_err_t rx_poeg_init (
    void )
```

Initialize POEG fault protection for all 4 motor channels.

Configures POEG Groups A-D for hardware motor fault protection:

1. Enables external pin detection (PIDE) on each group
2. Enables noise filter (NFEN) with PCLKB/8 sampling (~400ns)
3. Inverts input (INV) since DRV8263H nFAULT is active-low

4. Links each GPTW channel to its POEG group via GTINTAD
5. Configures ICU interrupts for vectors 188-191 at priority 14

After initialization, a DRV8263H fault will:

- Immediately disable GPTW PWM output (hardware, ~nanoseconds)
- Fire POEG ISR which sets fault flags in `shared_data`

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	All 4 POEG groups initialized successfully
<code>k_rx_err_hw_init_failed</code>	POEG register write verification failed

Precondition

GPTW module enabled (`MSTPCRA.MSTPA7 = 0`)
GTETRGR pins configured via MPC: `PDR=0` (input), `PSEL=0x1E` (GTETRGR function select)
`shared_data` initialized

Postcondition

POEG Groups A-D enabled with pin detection + noise filter
GPTW0-3 GTINTAD linked to POEG Groups A-D respectively
ICU vectors 188-191 enabled at priority 14
Any existing `nFAULT` assertion will trigger immediately

Note

Thread Safety: Call once during `hardware_init`, before motor tasks start

Warning

PIDE enable bit is write-once after reset – cannot be disabled

NASA Power of 10 Compliance:

- Rule 1: No goto, setjmp, recursion
- Rule 2: Loop bounded by `k_poeg_motor_count` (4)
- Rule 3: No dynamic allocation
- Rule 5: 3 preconditions, 4 postconditions
- Rule 7: Return value checked
- Rule 8: All constants as C23 typed enums

Here is the call graph for this function:

8.93.3.5 rx_poeg_software_stop()

```

rx_err_t rx_poeg_software_stop (
    uint8_t motor_index)

```

Trigger software emergency stop on a specific motor.

Sets the SSF (Software Stop Flag) in the POEGGn register, immediately disabling GPTW PWM output for the specified motor. This provides a firmware-controlled emergency stop independent of hardware faults.

Parameters

in	motor_index	Motor index (0-3)
----	-------------	-------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Software stop activated
k_rx_err_invalid_arg	motor_index >= 4

Postcondition

GPTW output immediately disabled for specified motor
SSF flag set in POEGGn register

See also

[rx_poeg_clear_software_stop\(\)](#) Release software stop

Since

Version 1.0.0

Trigger software emergency stop on a specific motor.

Sets POEGGn.SSF=1, force-disabling the GPTW outputs of the targeted motor as if a hardware fault had occurred. Does not touch the latched fault flags; once a Software Stop is set, the user must call [rx_poeg_clear_software_stop\(\)](#) to release.

Note

Safe from any context including ISR; single register write. Used by the safety supervisor for software-initiated E-Stop.

8.95 libs/rx_hal/inc/rx_port_utils.h File Reference

PORT utility functions for RX72N GPIO register access.

```

#include <stdint.h>
#include "rx72n_port_regs.h"
#include "rx_port_constants.h"

```

Include dependency graph for rx_port_utils.h:

This graph shows which files directly or indirectly include this file:

Functions

- static volatile `rx_port_regs_t * rx_port_get_base (uint8_t port)`
Map RX72N port number to PORT register base address.

8.95.1 Detailed Description

PORT utility functions for RX72N GPIO register access.

This file provides centralized utility functions for working with RX72N PORT (GPIO) registers. The primary function is mapping port numbers to register base addresses, which is critical for all GPIO operations in the STAR system.

8.95.1.1 Purpose and Design Rationale

The RX72N PORT peripheral has a unique type-grouped register layout where all PDR (direction) registers are contiguous, all PODR (output) registers are contiguous, etc. This differs from traditional MCUs where each port's registers are grouped together. These utilities abstract this complexity.

Key design decisions:

- Single source of truth: Port-to-address mapping centralized here
- Inline functions: Zero runtime overhead, optimized to direct register access
- Type safety: Uses C23 typed enums from `rx_port_constants.h`
- Package-specific: Only supports ports available on 144-pin LFQFP package

8.95.1.2 System Architecture Context

PORT utilities are foundational infrastructure used throughout the system:

```
Application Layer (hardware_pinout.h)
    v uses port constants
HAL Layer (rx_gpio.c, rx_mtu_encoder.c)
    v uses rx_port_get_base()
PORT Utils (THIS FILE - rx_port_utils.h)
    v maps to
Hardware Registers (rx72n_port_regs.h)
```

All GPIO configuration and motor control initialization depends on this mapping to access the correct hardware registers.

8.95.1.3 Hardware Requirements

Requirement	Specification
MCU	Renesas RX72N
Package	144-pin LFQFP
Available Ports	0-9, A-F, J (see rx_port_constants.h for per-port pin counts)
CPU Frequency	240 MHz
Memory Access	Direct register I/O

8.95.1.4 Performance Characteristics

- Execution time: 1-2 CPU cycles (inlined switch statement)
- Memory usage: Zero runtime overhead (compile-time constant folding)
- Code size: Minimal (optimized to direct address loading)
- Stack usage: Zero (inline function)

8.95.1.5 Usage Example

```
#include "rx_port_utils.h"
#include "rx_port_constants.h"

// Configure PORT D pin 0 as output (LED)
volatile rx_port_regs_t* port_d = rx_port_get_base(k_rx_port_d);
if (port_d != nullptr) {
    port_d->pmr &= ~(1 << 0); // GPIO mode
    port_d->pdr |= (1 << 0); // Output direction
    port_d->podr |= (1 << 0); // Set high
}

// Read PORT A pin 0 state (button input)
volatile rx_port_regs_t* port_a = rx_port_get_base(k_rx_port_a);
if (port_a != nullptr) {
    uint8_t button_state = (port_a->pdr >> 0) & 0x01;
}
```

NASA Power of 10 Compliance

Rule	Compliance	Details
1	↔ [OK]↔	No goto, setjmp, recursion - simple switch statement
2	↔ [OK]↔	No loops (switch is O(1) jump table)
3	↔ [OK]↔	No dynamic allocation (inline function)
4	↔ [OK]↔	Function is 43 lines (under 60 line limit)
5	↔ [OK]↔	Implicit validation: returns NULL for invalid port
6	↔ [OK]↔	Minimal scope (single parameter, local to function)
7	↔ [OK]↔	Return value must be checked (NULL validation required)
8	↔ [OK]↔	Uses C23 typed enums (k_rx_port_*), no magic numbers
9	↔ [OK]↔	Single level of dereferencing for register access
10	↔ [OK]↔	Compiles with -Wall -Wextra -Werror

SOLID Principles

Single Responsibility: This utility has one job - map port numbers to register base addresses. It does not configure pins, read/write values, or manage pin modes. Those responsibilities belong to higher-level modules.

Open/Closed: Extensible for new package sizes (144-pin, 176-pin) by adding new case statements without modifying existing mappings. Closed to modification of existing port addresses (hardware-defined).

Liskov Substitution: All port register pointers are identical types (rx_port_regs_t*), ensuring consistent register access patterns across all ports.

Interface Segregation: Provides minimal interface - single function for single purpose. Callers only depend on what they need (port-to-address).

Dependency Inversion: High-level GPIO drivers depend on this abstraction, not on hardcoded addresses. Easy to mock for unit testing.

8.95.2 Function Documentation

8.95.2.1 `rx_port_get_base()`

```
volatile rx\_port\_regs\_t * rx_port_get_base (  
    uint8_t port) [inline], [static]
```

Map RX72N port number to PORT register base address.

Converts a port number constant (`k_rx_port_*`) to the corresponding volatile PORT register structure pointer for hardware access. This is the single source of truth for port-to-address mapping in the entire STAR firmware.

Algorithm steps:

1. Receive port number as input parameter
2. Switch on port number (compiler optimizes to jump table)
3. For valid port: call corresponding `portX()` inline accessor
4. For invalid port: return NULL to signal error
5. Caller must validate non-NULL before dereferencing

Implementation details:

- Each case calls an inline accessor (`port0()`, `porta()`, etc.) defined in [rx72n_port_regs.h](#) which returns the typed register base address
- Compiler optimizes switch to direct jump table (O(1) lookup)
- Function is inline, so entire call optimizes to direct address load

- Invalid port numbers safely return NULL instead of accessing garbage memory

Package-specific behavior: Supports all ports physically available on 144-pin LQFP package:

- PORT0-9: Available (see rx_port_constants.h for per-port pin counts)
- PORTA-F: Available (PORTF has PF5 only)
- PORTJ: Available (PJ3, PJ5)
- Ports G-I, K-Q: Not available on 144-pin, will return nullptr

Control flow:

Parameters

in	port	Port number constant from <code>rx_port_constants.h</code> • Type: <code>uint8_t</code> (C23 typed enum <code>rx_port_num_t</code>) • Valid range: <code>k_rx_port_0</code> through <code>k_rx_port_j</code> • Units: N/A (enumerated constant) • Constraints: Must use <code>k_rx_port_*</code> constants, not raw integers • Invalid values: Any value not in <code>[0-5, 0x0A-0x0E, 0x13]</code> returns <code>nullptr</code>
----	------	--

Returns

Pointer to PORT register base structure, or `nullptr` if port invalid

Return values

Non-NULL	Valid port - pointer to volatile <code>rx_port_regs_t</code> structure with PDR, PODR, PIDR, PMR, etc. registers
NULL	Invalid port number - port not available on 144-pin LFQFP package, or invalid parameter value

Return Value Details:

Port Input	Return Value	Condition
<code>k_rx_port_0</code>	<code>&PORT0</code> registers	Port 0 (P00-P03, P05, P07)
<code>k_rx_port_1</code>	<code>&PORT1</code> registers	Port 1 (P12-P17)
<code>k_rx_port_2</code>	<code>&PORT2</code> registers	Port 2 (P20-P27)
<code>k_rx_port_3</code>	<code>&PORT3</code> registers	Port 3 (P30-P37)
<code>k_rx_port_4</code>	<code>&PORT4</code> registers	Port 4 (P40-P47)
<code>k_rx_port_5</code>	<code>&PORT5</code> registers	Port 5 (P50-P56)
<code>k_rx_port_6</code>	<code>&PORT6</code> registers	Port 6 (P60-P67)
<code>k_rx_port_7</code>	<code>&PORT7</code> registers	Port 7 (P70-P77)
<code>k_rx_port_8</code>	<code>&PORT8</code> registers	Port 8 (P80-P83, P86-P87)

Port Input	Return Value	Condition
<code>k_rx_port_9</code>	<code>&PORT9</code> registers	Port 9 (P90-P93)
<code>k_rx_port_a</code>	<code>&PORTA</code> registers	Port A (PA0-PA7)
<code>k_rx_port_b</code>	<code>&PORTB</code> registers	Port B (PB0-PB7)
<code>k_rx_port_c</code>	<code>&PORTC</code> registers	Port C (PC0-PC7)
<code>k_rx_port_d</code>	<code>&PORTD</code> registers	Port D (PD0-PD7)
<code>k_rx_port_e</code>	<code>&PORTE</code> registers	Port E (PE0-PE7)
<code>k_rx_port_f</code>	<code>&PORTF</code> registers	Port F (PF5 only)
<code>k_rx_port_j</code>	<code>&PORTJ</code> registers	Port J (PJ3, PJ5)
Any other value	NULL	Port not on 144-pin package

Precondition

None - function is always safe to call

Parameter should use `k_rx_port_*` constants (not validated at runtime)

Postcondition

If return value is non-NULL, pointer is valid volatile register address

If return value is nullptr, caller must not dereference (validation required)

No hardware state modified (read-only address calculation)

Invariant

Return value is either NULL or valid PORT register base address

Function has no side effects (pure address mapping)

Note

Thread Safety: Fully thread-safe and reentrant. No shared state, no hardware access, pure computation. Multiple threads can call simultaneously without synchronization.

Re-entrancy: Fully reentrant. No static variables, no globals. Safe for use in interrupt handlers and multi-threaded contexts.

Performance: Optimizes to 1-2 CPU cycles when inlined. Switch compiles to jump table (O(1) lookup). At 240 MHz: ~4-8 nanoseconds.

Memory: Zero stack usage (inlined). Zero heap usage. Zero static storage. Entire function optimizes to immediate address load.

Warning

NULL validation required: Caller MUST check return value before dereferencing. Failing to validate will cause nullptr fault if invalid port number is passed.

Attention

Package-specific: Only supports 144-pin LFQFP. Porting to 176-pin packages requires adding additional case statements for ports G-I, K-Q.

Example - Basic Usage:

```
#include "rx_port_utils.h"
#include "rx_port_constants.h"

// Configure PORT D as output
volatile rx_port_regs_t* port_d = rx_port_get_base(k_rx_port_d);
if (port_d != nullptr) {
    port_d->pdr = 0xFF; // All pins output
    port_d->podr = 0x00; // All pins low
}
```

Example - Error Handling:

```
// Attempt to access unavailable port (returns NULL)
volatile rx_port_regs_t* port_g = rx_port_get_base(0x10); // Port G
if (port_g == nullptr) {
    // Handle error - port not available on 144-pin package
    rx_log_error("GPIO", "Port G not available on this package");
    return k_rx_err_invalid_arg;
}
```

Example - Motor Control Initialization:

```
// Initialize motor driver enable pins (PORT E)
volatile rx_port_regs_t* port_e = rx_port_get_base(k_rx_port_e);
if (port_e != nullptr) {
    port_e->pmr &= ~0x0F; // Pins 0-3 GPIO mode
    port_e->pdr |= 0x0F; // Pins 0-3 output
    port_e->podr &= ~0x0F; // Motors disabled (active high)
}
```

Example - LED Status Indicator:

```
// Toggle status LED on PORT D pin 0
volatile rx_port_regs_t* port_d = rx_port_get_base(k_rx_port_d);
if (port_d != nullptr) {
    port_d->podr ^= (1 << 0); // Toggle PD0
}
```

NASA Power of 10 Compliance

- Rule 1 [OK] Simple control flow (switch only, no goto/recursion)
- Rule 2 [OK] No loops (O(1) switch statement)
- Rule 3 [OK] No dynamic allocation
- Rule 4 [OK] Function is 43 lines (under 60 line limit)
- Rule 5 [OK] Implicit validation: NULL return signals invalid input
- Rule 6 [OK] Minimal scope (single parameter, local to function)
- Rule 7 [OK] Return value MUST be validated by caller
- Rule 8 [OK] Uses C23 typed enums (k_rx_port_*), zero magic numbers
- Rule 9 [OK] Single level of pointer dereferencing for register access
- Rule 10 [OK] Compiles clean with -Wall -Wextra -Werror

00001 /**
00002  * @file rx_port_utils.h
00003  * @brief PORT utility functions for RX72N GPIO register access
00004  *
00005  * @details
00006  * This file provides centralized utility functions for working with RX72N PORT
00007  * (GPIO) registers. The primary function is mapping port numbers to register
00008  * base addresses, which is critical for all GPIO operations in the STAR system.
00009  *
00010  * ## Purpose and Design Rationale
00011  *
00012  * The RX72N PORT peripheral has a unique type-grouped register layout where
00013  * all PDR (direction) registers are contiguous, all PODR (output) registers
00014  * are contiguous, etc. This differs from traditional MCUs where each port's
00015  * registers are grouped together. These utilities abstract this complexity.
00016  *
00017  * Key design decisions:
00018  * - **Single source of truth**: Port-to-address mapping centralized here
00019  * - **Inline functions**: Zero runtime overhead, optimized to direct register access
00020  * - **Type safety**: Uses C23 typed enums from rx_port_constants.h
00021  * - **Package-specific**: Only supports ports available on 144-pin LFQFP package
00022  *
00023  * ## System Architecture Context
00024  *
00025  * PORT utilities are foundational infrastructure used throughout the system:
00026  * ```
00027  * Application Layer (hardware_pinout.h)
00028  *   v uses port constants
00029  * HAL Layer (rx_gpio.c, rx_mtu_encoder.c)
00030  *   v uses rx_port_get_base()
00031  * PORT Utils (THIS FILE - rx_port_utils.h)
00032  *   v maps to
00033  * Hardware Registers (rx72n_port_regs.h)
00034  * ```
00035  */

```

```

00036 * All GPIO configuration and motor control initialization depends on this
00037 * mapping to access the correct hardware registers.
00038 *
00039 * ## Hardware Requirements
00040 *
00041 * | Requirement          | Specification          |
00042 * |-----|-----|
00043 * | **MCU**              | Renesas RX72N          |
00044 * | **Package**          | 144-pin LFQFP          |
00045 * | **Available Ports**  | 0-9, A-F, J (see rx_port_constants.h for per-port pin counts) |
00046 * | **CPU Frequency**    | 240 MHz                |
00047 * | **Memory Access**    | Direct register I/O    |
00048 *
00049 * ## Performance Characteristics
00050 *
00051 * - **Execution time**: 1-2 CPU cycles (inlined switch statement)
00052 * - **Memory usage**: Zero runtime overhead (compile-time constant folding)
00053 * - **Code size**: Minimal (optimized to direct address loading)
00054 * - **Stack usage**: Zero (inline function)
00055 *
00056 * ## Usage Example
00057 *
00058 * @code
00059 * #include "rx_port_utils.h"
00060 * #include "rx_port_constants.h"
00061 *
00062 * // Configure PORT D pin 0 as output (LED)
00063 * volatile rx_port_regs_t* port_d = rx_port_get_base(k_rx_port_d);
00064 * if (port_d != nullptr) {
00065 *     port_d->pmr &= ~(1 << 0); // GPIO mode
00066 *     port_d->pdr |= (1 << 0); // Output direction
00067 *     port_d->podr |= (1 << 0); // Set high
00068 * }
00069 *
00070 * // Read PORT A pin 0 state (button input)
00071 * volatile rx_port_regs_t* port_a = rx_port_get_base(k_rx_port_a);
00072 * if (port_a != nullptr) {
00073 *     uint8_t button_state = (port_a->pdr >> 0) & 0x01;
00074 * }
00075 * @endcode
00076 *
00077 * @par Module Dependencies
00078 * - rx72n_port_regs.h: PORT register structure definitions
00079 * - rx_port_constants.h: Port number constants (k_rx_port_*)
00080 *
00081 * @par NASA Power of 10 Compliance
00082 *
00083 * | Rule | Compliance | Details |
00084 * |-----|-----|
00085 * | 1 | [OK] | No goto, setjmp, recursion - simple switch statement |
00086 * | 2 | [OK] | No loops (switch is O(1) jump table) |
00087 * | 3 | [OK] | No dynamic allocation (inline function) |
00088 * | 4 | [OK] | Function is 43 lines (under 60 line limit) |
00089 * | 5 | [OK] | Implicit validation: returns NULL for invalid port |
00090 * | 6 | [OK] | Minimal scope (single parameter, local to function) |
00091 * | 7 | [OK] | Return value must be checked (NULL validation required) |
00092 * | 8 | [OK] | Uses C23 typed enums (k_rx_port_*), no magic numbers |
00093 * | 9 | [OK] | Single level of dereferencing for register access |
00094 * | 10 | [OK] | Compiles with -Wall -Wextra -Werror |
00095 *
00096 * @par SOLID Principles
00097 *
00098 * **Single Responsibility**: This utility has one job - map port numbers to
00099 * register base addresses. It does not configure pins, read/write values, or
00100 * manage pin modes. Those responsibilities belong to higher-level modules.
00101 *
00102 * **Open/Closed**: Extensible for new package sizes (144-pin, 176-pin) by
00103 * adding new case statements without modifying existing mappings. Closed to
00104 * modification of existing port addresses (hardware-defined).
00105 *
00106 * **Liskov Substitution**: All port register pointers are identical types
00107 * (rx_port_regs_t*), ensuring consistent register access patterns across
00108 * all ports.
00109 *
00110 * **Interface Segregation**: Provides minimal interface - single function for
00111 * single purpose. Callers only depend on what they need (port-to-address).
00112 *
00113 * **Dependency Inversion**: High-level GPIO drivers depend on this abstraction,
00114 * not on hardcoded addresses. Easy to mock for unit testing.
00115 *
00116 * @see docs/sections/03_hardware_pinout.tex Complete GPIO pin assignments
00117 * @see rx72n_port_regs.h PORT register structure and memory map
00118 * @see rx_port_constants.h Port number constant definitions
00119 *
00120 * @author Locked, Inc.

00127
00128 #include <stdint.h>
00129
00130 #include "rx72n_port_regs.h"
00131 #include "rx_port_constants.h"
00132
00133 #ifdef __cplusplus
00134 extern "C" {
00135 #endif
00136
00137 /**
00138  * @brief Map RX72N port number to PORT register base address
00139  *
00140  * @details
00141  * Converts a port number constant (k_rx_port_*) to the corresponding volatile
00142  * PORT register structure pointer for hardware access. This is the **single
00143  * source of truth** for port-to-address mapping in the entire STAR firmware.
00144  *
00145  * **Algorithm steps**:
00146  * 1. Receive port number as input parameter
00147  * 2. Switch on port number (compiler optimizes to jump table)
00148  * 3. For valid port: call corresponding portX() inline accessor
00149  * 4. For invalid port: return NULL to signal error
00150  * 5. Caller must validate non-NULL before dereferencing
00151  *
00152  * **Implementation details**:
00153  * - Each case calls an inline accessor (port0(), porta(), etc.) defined in
00154  *   rx72n_port_regs.h which returns the typed register base address
00155  * - Compiler optimizes switch to direct jump table (O(1) lookup)
00156  * - Function is inline, so entire call optimizes to direct address load
00157  * - Invalid port numbers safely return NULL instead of accessing garbage memory
00158  *
00159  * **Package-specific behavior**:
00160  * Supports all ports physically available on 144-pin LFQFP package:
00161  * - PORT0-9: Available (see rx_port_constants.h for per-port pin counts)
00162  * - PORTA-F: Available (PORTF has PF5 only)
00163  * - PORTJ: Available (PJ3, PJ5)
00164  * - Ports G-I, K-Q: Not available on 144-pin, will return nullptr
00165  *
00166  * **Control flow**:

00224 *
00225 * @pre None - function is always safe to call
00226 * @pre Parameter should use k_rx_port_* constants (not validated at runtime)
00227 *
00228 * @post If return value is non-NULL, pointer is valid volatile register address
00229 * @post If return value is nullptr, caller must not dereference (validation required)
00230 * @post No hardware state modified (read-only address calculation)
00231 *
00232 * @invariant Return value is either NULL or valid PORT register base address
00233 * @invariant Function has no side effects (pure address mapping)
00234 *
00235 * @note **Thread Safety**: Fully thread-safe and reentrant. No shared state,
00236 * no hardware access, pure computation. Multiple threads can call
00237 * simultaneously without synchronization.
00238 *
00239 * @note **Re-entrancy**: Fully reentrant. No static variables, no globals.
00240 * Safe for use in interrupt handlers and multi-threaded contexts.
00241 *
00242 * @note **Performance**: Optimizes to 1-2 CPU cycles when inlined. Switch
00243 * compiles to jump table (O(1) lookup). At 240 MHz: ~4-8 nanoseconds.
00244 *
00245 * @note **Memory**: Zero stack usage (inlined). Zero heap usage. Zero static
00246 * storage. Entire function optimizes to immediate address load.
00247 *
00248 * @warning **NULL validation required**: Caller MUST check return value before
00249 * dereferencing. Failing to validate will cause nullptr fault if
00250 * invalid port number is passed.
00251 *
00252 * @attention **Package-specific**: Only supports 144-pin LQFP. Porting to
00253 * 176-pin packages requires adding additional case statements
00254 * for ports G-I, K-Q.
00255 *
00256 * @par Example - Basic Usage:
00257 * @code
00258 * #include "rx_port_utils.h"
00259 * #include "rx_port_constants.h"
00260 *
00261 * // Configure PORT D as output

TMR interrupt source bitmask (may be OR-combined).

Functions

- `rx_err_t rx_tmr_init` (`const rx_tmr_config_t *config`)
Initialise a TMR channel (or cascaded pair).
- `rx_err_t rx_tmr_start` (`rx_tmr_channel_t channel`)
Start counting on a TMR channel.
- `rx_err_t rx_tmr_stop` (`rx_tmr_channel_t channel`)
Stop a TMR channel counter.
- `rx_err_t rx_tmr_read` (`rx_tmr_channel_t channel`, `uint16_t *value`)
Read the current TMR counter value.
- `rx_err_t rx_tmr_set_period_us` (`rx_tmr_channel_t channel`, `uint32_t period_us`)
Set the compare-match period in microseconds.
- `rx_err_t rx_tmr_register_compare_match_isr` (`rx_tmr_channel_t channel`, `rx_tmr_isr_callback_t callback`)
Register an interrupt callback for compare-match / overflow events.
- `rx_err_t rx_tmr_deinit` (`rx_tmr_channel_t channel`)
Deinitialise a TMR channel.

8.97.1 Detailed Description

TMR HAL Driver for RX72N 8-Bit Timer (TMRb).

Hardware abstraction layer for the RX72N TMR peripheral, providing four 8-bit timers (TMR0..TMR3) organized as two units of two channels. Each unit can be used either as two independent 8-bit timers or as a single 16-bit cascaded timer (TMR01 or TMR23).

8.97.1.1 Architecture

Application Layer: periodic tasks, soft PWM, low-speed triggers
 HAL Layer: rx_tmr.h/c (THIS MODULE - **register** access)
 Register Layer: rx72n_tmr_regs.h (memory-mapped I/O)

8.97.1.2 Unit and Cascade Layout

Unit	Channels	Module Stop	Cascade Name
0	TMR0, TMR1	MSTPCRA.MSTPA5	TMR01
1	TMR2, TMR3	MSTPCRA.MSTPA4	TMR23

In a cascaded pair, the even channel (TMR0/TMR2) holds the upper 8 bits and the odd channel (TMR1/TMR3) holds the lower 8 bits.

8.97.1.3 Clock Sources

The TMR counts on either an external signal at the TMCI pin or an internal PCLK-divided signal:

Source	Divider	Tick @ PCLKB=60 MHz	8-bit max period
Internal	PCLK/1	16.67 ns	4.27 us
Internal	PCLK/2	33.33 ns	8.53 us
Internal	PCLK/8	133.3 ns	34.13 us
Internal	PCLK/32	533.3 ns	136.5 us
Internal	PCLK/64	1.067 us	273.1 us
Internal	PCLK/1024	17.07 us	4.369 ms
Internal	PCLK/8192	136.5 us	34.95 ms
External	rising	external	external
External	falling	external	external
External	both	external	external

16-bit cascaded mode extends the max period by 256x.

8.97.1.4 Interrupts

TMR compare-match A/B and overflow interrupts are routed via the ICU SELECTB (Software Configurable Interrupt B) mechanism. The driver provides a callback registration hook so higher layers can install handlers without touching the interrupt controller directly.

NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: All loops bounded
- Rule 3: No dynamic memory allocation
- Rule 4: All functions < 60 lines
- Rule 5: Minimum 2 validation checks per function
- Rule 6: Variables at smallest scope
- Rule 7: All return values checked
- Rule 8: C23 typed enums, minimal macros
- Rule 9: Function pointers allowed (DIP) for ISR registration
- Rule 10: Compiles with -Wall -Wextra -Werror

SOLID Principles

- S: Only TMR hardware access (no scheduling, no signal logic)
- O: Extensible via [rx_tmr_config_t](#)
- L: Consistent rx_err_t return semantics
- I: Focused API: init, start/stop, read, set period, register ISR, deinit
- D: Depends on register abstractions, not raw addresses

8.97.2 Data Structure Documentation

8.97.2.1 struct rx_tmr_config_t

TMR channel configuration.

Passed to `rx_tmr_init()` to configure one channel (independent mode) or one cascaded pair (16-bit mode). In cascade mode, `channel` must be an even channel (`k_tmr_channel_0` or `k_tmr_channel_2`) and the paired odd channel is configured automatically.

Example - 1 ms periodic interrupt on TMR0

```
rx_tmr_config_t cfg = {
    .channel      = k_tmr_channel_0,
    .mode         = k_tmr_mode_8bit_independent,
    .clock_source = k_tmr_clock_pclk_div_1024,
    .counter_clear = k_tmr_clear_cmp_match_a,
    .output_a     = k_tmr_output_no_change,
    .output_b     = k_tmr_output_no_change,
    .irq_mask     = k_tmr_irq_cmp_match_a,
};
rx_err_t err = rx_tmr_init(&cfg);
```

Invariant

`channel` is one of `k_tmr_channel_0..3`

`clock_source` is a valid `rx_tmr_clock_source_t` value

Since

Version 1.0.0

Definition at line 235 of file `rx_tmr.h`.

Collaboration diagram for `rx_tmr_config_t`:

Data Fields

rx_tmr_channel_t	channel	TMR channel (cascade mode requires an even channel).
rx_tmr_clock_source_t	clock_source	Clock source (internal divider or external edge).
rx_tmr_counter_clear_t	counter_clear	Counter clear trigger.
uint8_t	irq_mask	Interrupt enable bitmask (OR of rx_tmr_irq_source_t values). Set to k_tmr_irq_none to leave all TMR interrupts disabled.
rx_tmr_mode_t	mode	Operating mode (8-bit independent or 16-bit cascade).
rx_tmr_output_t	output_a	TMO pin behaviour on TCORA compare match.
rx_tmr_output_t	output_b	TMO pin behaviour on TCORB compare match.

8.97.3 Typedef Documentation

8.97.3.1 rx`tmr`isr`callback`[t](#)

```
typedef void(* rx_tmr_isr_callback_t) (rx\_tmr\_channel\_t channel)
```

User callback for compare-match / overflow events.

Parameters

in	channel	TMR channel that raised the event
----	---------	-----------------------------------

Note

Called from interrupt context; keep implementations short.

Since

Version 1.0.0

Definition at line 270 of file [rx_tmr.h](#).

8.97.4 Enumeration Type Documentation

8.97.4.1 rx`tmr`channel`[t](#)

```
enum rx\_tmr\_channel\_t : uint8_t
```

TMR channel identifiers.

Four 8-bit TMR channels are available. Channels within the same unit (TMR0+TMR1 in unit 0, TMR2+TMR3 in unit 1) may be cascaded into a 16-bit counter; see [rx_tmr_mode_t](#) and [rx_tmr_init\(\)](#).

Since

Version 1.0.0

Enumerator

k_tmr_channel_0	TMR0 - unit 0 even channel
k_tmr_channel_1	TMR1 - unit 0 odd channel
k_tmr_channel_2	TMR2 - unit 1 even channel
k_tmr_channel_3	TMR3 - unit 1 odd channel

Definition at line 114 of file [rx_tmr.h](#).

```
00114      : uint8_t {
00115  k_tmr_channel_0 = 0, /**< TMR0 - unit 0 even channel */
00116  k_tmr_channel_1 = 1, /**< TMR1 - unit 0 odd channel */
00117  k_tmr_channel_2 = 2, /**< TMR2 - unit 1 even channel */
00118  k_tmr_channel_3 = 3, /**< TMR3 - unit 1 odd channel */
00119 } rx_tmr_channel_t;
```

8.97.4.2 rx_tmr_clock_source_t

```
enum rx\_tmr\_clock\_source\_t : uint8_t
```

TMR clock source selection.

Combines the CSS (clock source) and CKS (clock select) fields of TCCR into a single configuration value. Internal sources use PCLK dividers; external sources use the TMCI input pin with selectable edge detection.

Since

Version 1.0.0

Enumerator

k_tmr_clock_pclk_div_1	Internal PCLK / 1
k_tmr_clock_pclk_div_2	Internal PCLK / 2

00155  k_tmr_clock_pclk_div_1024 = 5, /**< Internal PCLK / 1024 */
00156  k_tmr_clock_pclk_div_8192 = 6, /**< Internal PCLK / 8192 */
00157  k_tmr_clock_external_rising = 7, /**< External TMCI rising-edge count */
00158  k_tmr_clock_external_falling = 8, /**< External TMCI falling-edge count */
00159  k_tmr_clock_external_both  = 9, /**< External TMCI both-edge count */
00160 } rx_tmr_clock_source_t;
```

8.97.4.3 rx`tmr`counter`clear`

```
enum rx_tmr_counter_clear_t : uint8_t
```

Counter clear source (CCLR field of TCR).

Since

Version 1.0.0

Enumerator

<code>k_tmr_clear_disabled</code>	Counter never cleared by TMR itself
<code>k_tmr_clear_cmp_match_a</code>	Clear on TCORA compare match
<code>k_tmr_clear_cmp_match_b</code>	Clear on TCORB compare match
<code>k_tmr_clear_external_reset</code>	Clear on external reset input

Definition at line 168 of file [rx_tmr.h](#).

```
00168      : uint8_t {
00169  k_tmr_clear_disabled    = 0, /**< Counter never cleared by TMR itself */
00170  k_tmr_clear_cmp_match_a = 1, /**< Clear on TCORA compare match */
00171  k_tmr_clear_cmp_match_b = 2, /**< Clear on TCORB compare match */
00172  k_tmr_clear_external_reset = 3, /**< Clear on external reset input */
00173 } rx_tmr_counter_clear_t;
```

8.97.4.4 rx`tmr`irq`source`

```
enum rx_tmr_irq_source_t : uint8_t
```

TMR interrupt source bitmask (may be OR-combined).

Since

Version 1.0.0

Enumerator

k_tmr_irq_none	No interrupts enabled
k_tmr_irq_cmp_match_a	Enable CMIA (TCORA compare match)
k_tmr_irq_cmp_match_b	Enable CMIB (TCORB compare match)
k_tmr_irq_overflow	Enable OVI (TCNT overflow)

Definition at line 194 of file [rx_tmr.h](#).

```
00194      : uint8_t {
00195      k_tmr_irq_none      = 0x00, /**< No interrupts enabled          */
00196      k_tmr_irq_cmp_match_a = 0x01, /**< Enable CMIA (TCORA compare match) */
00197      k_tmr_irq_cmp_match_b = 0x02, /**< Enable CMIB (TCORB compare match) */
00198      k_tmr_irq_overflow    = 0x04, /**< Enable OVI (TCNT overflow)      */
00199 } rx_tmr_irq_source_t;
```

8.97.4.5 rx_tmr_mode_t

```
enum rx_tmr_mode_t : uint8_t
```

TMR operating mode (independent 8-bit vs cascaded 16-bit).

In 16-bit cascade mode, the even channel (TMR0/TMR2) provides the upper byte and the odd channel (TMR1/TMR3) provides the lower byte. When initialising cascade mode, pass the even channel number; the driver configures both channels accordingly.

Since

Version 1.0.0

Enumerator

k_tmr_mode_8bit_independent	Two independent 8-bit counters per unit
k_tmr_mode_16bit_cascade	Cascaded 16-bit counter (TMR01 or TMR23)

Definition at line 133 of file [rx_tmr.h](#).

```
00133      : uint8_t {
00134      k_tmr_mode_8bit_independent = 0, /**< Two independent 8-bit counters per unit */

00186 } rx_tmr_output_t;
```

8.97.5 Function Documentation

8.97.5.1 rx'tmr'deinit()

```
rx_err_t rx_tmr_deinit (
    rx_tmr_channel_t channel) [nodiscard]
```

Deinitialise a TMR channel.

Stops the counter, clears TCR/TCSR/TCCR, zeroes TCNT, removes any installed ISR callback, and marks the channel as uninitialised. The module stop bit is NOT asserted because the paired channel in the same unit may still be active.

Parameters

in	channel	TMR channel (cascade: pass the even channel)
----	---------	--

Returns

rx_err_t Error code

Return values

k_rx_ok	Channel released
k_rx_err_invalid_arg	Channel out of range

Precondition

(none - safe to call on uninitialised channel)

Postcondition

Channel registers cleared
Internal init flag cleared

Note

Thread Safety: Not thread-safe.

8.97.5.2 rx'tmr'init()

```
rx_err_t rx_tmr_init (  
    const rx_tmr_config_t * config) [nodiscard]
```

Initialise a TMR channel (or cascaded pair).

Enables the module stop clock for the channel's unit (MSTPA5 for unit 0, MSTPA4 for unit 1), stops the counter, writes TCR/TCSR/TCCR/TCORA/ TCORB according to the supplied configuration, and clears TCNT to zero. In cascade mode, both channels of the unit are configured in one call.

Parameters

in	config	Pointer to configuration (non-NULL)
----	--------	-------------------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Success
k_rx_err_null_ptr	config is NULL
k_rx_err_invalid_arg	Invalid channel, clock, clear, output, or a cascade request on an odd channel
k_rx_err_invalid_state	Channel already initialised

Precondition

System clocks configured (PCLKB running)

In cascade mode, config->channel is k_tmr_channel_0 or k_tmr_channel_2 (even channel)

Postcondition

Channel counter stopped at 0

Module clock enabled (MSTPCRA bit cleared)

Internal init flag set

Note

Not thread-safe; call from main-task context at startup.

8.97.5.3 rx'tmr'read()

```
rx_err_t rx_tmr_read (  
    rx_tmr_channel_t channel,  
    uint16_t * value) [nodiscard]
```

Read the current TMR counter value.

For 8-bit mode, *value holds the 8-bit TCNT zero-extended to uint16_t. For 16-bit cascade mode, *value holds the full 16-bit value (even channel = upper byte, odd channel = lower byte).

Parameters

in	channel	TMR channel (cascade: pass the even channel)
out	value	Pointer receiving counter value (non-NULL)

Returns

rx_err_t Error code

Return values

k_rx_ok	Success
k_rx_err_null_ptr	value is NULL
k_rx_err_invalid_arg	Channel out of range
k_rx_err_invalid_state	Channel not initialised

Precondition

Channel initialised

Postcondition

*value contains counter at time of read

Note

Thread Safety: Safe - single volatile read.

8.97.5.4 rx_tmr_register_compare_match_isr()

```

rx_err_t rx_tmr_register_compare_match_isr (
    rx_tmr_channel_t channel,
    rx_tmr_isr_callback_t callback) [nodiscard]

```

Register an interrupt callback for compare-match / overflow events.

Installs a user callback invoked from the ICU SELECTB dispatcher when any of the channel's enabled TMR interrupts (CMIA, CMIB, or OVI) fire. The driver's ISR shim clears the source flag before calling back. Pass NULL to deregister.

Parameters

in	channel	TMR channel (cascade: pass the even channel)
----	---------	--

in	callback	User callback, or NULL to deregister
----	----------	--------------------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Success
k_rx_err_invalid_arg	Channel out of range

Precondition

Channel initialised with desired irq_mask

Postcondition

callback is installed (or cleared) atomically

Note

Thread Safety: Safe - function-pointer write is atomic on RX.

Since

Version 1.0.0

Definition at line 616 of file [rx_tmr.c](#).

```

00617 {
00618     if ((uint8_t)channel >= k_tmr_channel_count_internal) {
00619         return k_rx_err_invalid_arg;
00620     }
00621     s_tmr_callback[(uint8_t)channel] = callback;
00622     return k_rx_ok;
00623 }
```

References [k_tmr_channel_count_internal](#), and [s_tmr_callback](#).

8.97.5.5 rx`tmr`set`period`us()

```

rx_err_t rx_tmr_set_period_us (
    rx_tmr_channel_t channel,
    uint32_t period_us) [nodiscard]
```

Set the compare-match period in microseconds.

Recomputes and writes TCORA so that a TCORA compare match fires every period_us microseconds using the channel's configured clock source. TCORB is untouched. The caller must ensure the period fits into the channel counter width (8-bit single channel max = ~35 ms at PCLK/8192; 16-bit cascade max ~ = 8.9 s at PCLK/8192).

The underlying formula is $tcora = \text{round}(\text{period_us} * \text{PCLK_Hz} / (\text{divider} * 1e6)) - 1$, where divider is 1/2/8/32/64/1024/8192 according to the configured clock_source. External clock sources are not supported.

Parameters

in	channel	TMR channel (cascade: pass the even channel)
in	period_us	Desired period in microseconds (1..max for mode)

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, TCORA updated
k_rx_err_invalid_arg	Channel out of range, period=0, period too large for the selected divider, or external clock source
k_rx_err_invalid_state	Channel not initialised

Precondition

Channel initialised with an internal-clock clock_source

Postcondition

TCORA holds the rounded tick count - 1

Note

Thread Safety: Safe - single register write.

8.97.5.6 rx_tmr_start()

```

rx_err_t rx_tmr_start (
    rx_tmr_channel_t channel) [nodiscard]

```

Start counting on a TMR channel.

Writes the configured clock-source bits into TCCR so the counter begins advancing on each selected clock edge. Channel must have been initialised via [rx_tmr_init\(\)](#).

Parameters

in	channel	TMR channel (cascade: pass the even channel)
----	---------	--

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Counter started
<code>k_rx_err_invalid_arg</code>	Channel out of range
<code>k_rx_err_invalid_state</code>	Channel not initialised

Precondition

Channel initialised via [rx_tmr_init\(\)](#)

Postcondition

TCCR programmed with clock source (counter running)

Note

Thread Safety: Safe - single register write.

8.97.5.7 rx_tmr_stop()

```
rx_err_t rx_tmr_stop (
    rx_tmr_channel_t channel) [nodiscard]
```

Stop a TMR channel counter.

Writes 0 into TCCR CKS/CSS to disable the clock input. The TCNT value is preserved.

Parameters

in	channel	TMR channel (cascade: pass the even channel)
----	---------	--

Returns

rx_err_t Error code

Return values

k_rx_ok	Counter stopped
k_rx_err_invalid_arg	Channel out of range
k_rx_err_invalid_state	Channel not initialised

Precondition

Channel initialised

Postcondition

Counter no longer advances

TCNT preserved

00002  * @file rx_tmr.h
00003  * @brief TMR HAL Driver for RX72N 8-Bit Timer (TMRb)
00004  *
00005  * @details
00006  * Hardware abstraction layer for the RX72N TMR peripheral, providing
00007  * four 8-bit timers (TMR0..TMR3) organized as two units of two channels.
00008  * Each unit can be used either as two independent 8-bit timers or as a
00009  * single 16-bit cascaded timer (TMR01 or TMR23).
00010  *
00011  * ## Architecture
00012  *
00013  * ```
00014  * Application Layer:  periodic tasks, soft PWM, low-speed triggers
00015  *                      |
00016  * HAL Layer:          rx_tmr.h/c (THIS MODULE - register access)
00017  *                      |
00018  * Register Layer:     rx72n_tmr_regs.h (memory-mapped I/O)
00019  * ```
00020  *
00021  * ## Unit and Cascade Layout
00022  *
00023  * | Unit | Channels | Module Stop | Cascade Name |
00024  * |-----|-----|-----|-----|
00025  * | 0 | TMR0, TMR1 | MSTPCRA.MSTPA5 | TMR01 |
00026  * | 1 | TMR2, TMR3 | MSTPCRA.MSTPA4 | TMR23 |
00027  *
00028  * In a cascaded pair, the even channel (TMR0/TMR2) holds the upper 8 bits
00029  * and the odd channel (TMR1/TMR3) holds the lower 8 bits.
00030  *
00031  * ## Clock Sources
00032  *
00033  * The TMR counts on either an external signal at the TMCI pin or an
00034  * internal PCLK-divided signal:
00035  *
00036  * | Source | Divider | Tick @ PCLKB=60 MHz | 8-bit max period |
00037  * |-----|-----|-----|-----|
00038  * | Internal | PCLK/1 | 16.67 ns | 4.27 us |
00039  * | Internal | PCLK/2 | 33.33 ns | 8.53 us |
00040  * | Internal | PCLK/8 | 133.3 ns | 34.13 us |
00041  * | Internal | PCLK/32 | 533.3 ns | 136.5 us |
00042  * | Internal | PCLK/64 | 1.067 us | 273.1 us |
00043  * | Internal | PCLK/1024 | 17.07 us | 4.369 ms |
00044  * | Internal | PCLK/8192 | 136.5 us | 34.95 ms |
00045  * | External | rising | external | external |
00046  * | External | falling | external | external |
00047  * | External | both | external | external |
00048  *
00049  * 16-bit cascaded mode extends the max period by 256x.
00050  *
00051  * ## Interrupts
00052  *
00053  * TMR compare-match A/B and overflow interrupts are routed via the ICU
00054  * SELECTB (Software Configurable Interrupt B) mechanism. The driver
00055  * provides a callback registration hook so higher layers can install
00056  * handlers without touching the interrupt controller directly.
00057  *
00058  * @par NASA Power of 10 Compliance

```

```

00059 * - Rule 1: No goto, setjmp, or recursion
00060 * - Rule 2: All loops bounded
00061 * - Rule 3: No dynamic memory allocation
00062 * - Rule 4: All functions < 60 lines
00063 * - Rule 5: Minimum 2 validation checks per function
00064 * - Rule 6: Variables at smallest scope
00065 * - Rule 7: All return values checked
00066 * - Rule 8: C23 typed enums, minimal macros
00067 * - Rule 9: Function pointers allowed (DIP) for ISR registration
00068 * - Rule 10: Compiles with -Wall -Wextra -Werror
00069 *
00070 * @par SOLID Principles
00071 * - **S**: Only TMR hardware access (no scheduling, no signal logic)
00072 * - **O**: Extensible via rx_tmr_config_t
00073 * - **I**: Consistent rx_err_t return semantics
00074 * - **I**: Focused API: init, start/stop, read, set period, register ISR, deinit
00075 * - **D**: Depends on register abstractions, not raw addresses
00076 *
00077 * @see rx72n_tmr_regs.h TMR register definitions
00078 * @see rx_tpu.h TPU HAL (16-bit pulse unit)
00079 *

Deinitialize TPU channel.

8.99.1 Detailed Description

TPU HAL Driver for RX72N 16-Bit Timer Pulse Unit (Phase Counting).

Hardware abstraction layer for the RX72N TPU peripheral, focused on phase counting mode for quadrature encoder input. This driver provides low-level channel configuration, counter access, and direction reading.

8.99.1.1 STAR Project Usage

The TPU is used for rear wheel encoder decoding. Front wheels use the MTU peripheral (see [rx_mtu.h](#) / [rx_mtu_encoder.h](#)).

Encoder	Peripheral	Channel	Phase A Pin	Phase B Pin
0 (FL)	MTU1	MTU1	P24/MTCLKA (pin 33)	P25/MTCLKB (pin 32)
1 (FR)	MTU2	MTU2	PA1/MTCLKC (pin 96)	PC5/MTCLKD (pin 62)
2 (BR)	TPU1	TPU1	PC2/TCLKA (pin 70)	PA3/TCLKB (pin 94)
3 (BL)	TPU2	TPU2	PC0/TCLKC (pin 75)	PB3/TCLKD (pin 82)

8.99.1.2 Architecture

```

Application Layer: motor_control_task.c (250 Hz PID loop)
                  |
Encoder Layer:    rx_encoder_tpu.c (overflow handling, velocity)
                  |
HAL Layer:        rx_tpu.h/c (THIS MODULE - register access)
                  |
Register Layer:   rx72n_tpu_regs.h (memory-mapped I/O)

```

8.99.1.3 Key Features

- Phase counting mode 4 (4x resolution, all edges)
- 16-bit up/down counter with direction flag
- Hardware noise filter on input pins
- Module stop control for power management

Performance

Operation	Time	Notes
rx_tpu_init_phase()	~20 us	One-time setup
rx_tpu_read_count()	~0.5 us	Single register read
rx_tpu_read_direction()	~0.5 us	Single register read
rx_tpu_start()	~0.5 us	Single register write

NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: All loops bounded
- Rule 3: No dynamic memory allocation
- Rule 4: All functions < 60 lines
- Rule 5: Minimum 2 validation checks per function
- Rule 6: Variables at smallest scope
- Rule 7: All return values checked
- Rule 8: C23 typed enums, minimal macros
- Rule 9: Single-level pointers only
- Rule 10: Compiles with -Wall -Wextra -Werror

SOLID Principles

- S: Only TPU hardware access (no encoder logic)
- O: Extensible via [rx_tpu_config_t](#)
- L: Consistent rx_err_t return semantics
- I: Focused API: init, start, stop, read, reset, deinit
- D: Depends on register abstractions, not raw addresses

8.99.2 Data Structure Documentation

8.99.2.1 struct rx'tpu'config't

TPU phase counting configuration.

Configuration parameters for initializing a TPU channel in phase counting mode. Passed to [rx_tpu_init_phase_count\(\)](#).

Example

```
rx_tpu_config_t config = {
    .channel    = k_tpu_channel_1,
    .phase_mode = k_tpu_phase_mode_4,
};
rx_err_t err = rx_tpu_init_phase_count(&config);
```

Invariant

channel must be 1, 2, 4, or 5 (phase counting capable)
phase_mode must be 1-4

See also

[rx_tpu_init_phase_count\(\)](#) Initialization function

Since

Version 1.0.0

Definition at line 167 of file [rx_tpu.h](#).

Collaboration diagram for rx_tpu_config_t:

Data Fields

rx_tpu_channel_t	channel	TPU channel to configure. Must be a phase-counting-capable channel (1, 2, 4, or 5).
----------------------------------	---------	--

<code>rx_tpu_phase_mode_t</code>	<code>phase_mode</code>	Phase counting mode (1-4). Selects the counting resolution. Mode 4 recommended for maximum resolution (4 counts per encoder pulse).
----------------------------------	-------------------------	--

8.99.3 Enumeration Type Documentation

8.99.3.1 `rx_tpu_channel_t`

enum `rx_tpu_channel_t` : `uint8_t`

TPU channel identifiers for phase counting.

Identifies TPU channels that support phase counting mode. Only TPU1/2/4/5 can do phase counting; TPU0 and TPU3 cannot.

STAR Channel Assignments

Value	Channel	Use	Clock Pins
1	TPU1	Back-right encoder	TCLKA + TCLKB
2	TPU2	Back-left encoder	TCLKC + TCLKD
4	TPU4	Available	TCLKC + TCLKD
5	TPU5	Available	TCLKA + TCLKB

Since

Version 1.0.0

Enumerator

<code>k_tpu_channel_1</code>	TPU1: back-right encoder (TCLKA/TCLKB)
<code>k_tpu_channel_2</code>	TPU2: back-left encoder (TCLKC/TCLKD)
<code>k_tpu_channel_4</code>	TPU4: available (TCLKC/TCLKD, paired with TPU2)
<code>k_tpu_channel_5</code>	TPU5: available (TCLKA/TCLKB, paired with TPU1)

Definition at line 112 of file `rx_tpu.h`.

```

00112         : uint8_t {
00113   k_tpu_channel_1 = 1, /**< TPU1: back-right encoder (TCLKA/TCLKB) */
00114   k_tpu_channel_2 = 2, /**< TPU2: back-left encoder (TCLKC/TCLKD) */
00115   k_tpu_channel_4 = 4, /**< TPU4: available (TCLKC/TCLKD, paired with TPU2) */
00116   k_tpu_channel_5 = 5, /**< TPU5: available (TCLKA/TCLKB, paired with TPU1) */
00117 } rx_tpu_channel_t;

```

8.99.3.2 rx'tpu'phase'mode't

enum [rx_tpu_phase_mode_t](#) : uint8_t

TPU phase counting mode selection.

Selects the phase counting resolution. Mode 4 (4x) provides the highest resolution by counting all edges of both A and B phases.

Mode Comparison

Mode	Resolution	Edges Counted	Counts/PPR
1	1x	A-phase rising only	1
2	1x	B-phase rising only	1
3	2x	A-phase rising and falling	2
4	4x	All edges of A and B phases	4

Since

Version 1.0.0

Enumerator

k_tpu_phase_mode_1	1x resolution (A rising only)
k_tpu_phase_mode_2	1x resolution (B rising only)
k_tpu_phase_mode_3	2x resolution (A both edges)
k_tpu_phase_mode_4	4x resolution (all edges) - STAR default

Definition at line 137 of file [rx_tpu.h](#).

```

00137     : uint8_t {
00138   k_tpu_phase_mode_1 = 1, /**< 1x resolution (A rising only) */
00139   k_tpu_phase_mode_2 = 2, /**< 1x resolution (B rising only) */
00140   k_tpu_phase_mode_3 = 3, /**< 2x resolution (A both edges) */
00141   k_tpu_phase_mode_4 = 4, /**< 4x resolution (all edges) - STAR default */
00142 } rx_tpu_phase_mode_t;
```

8.99.4 Function Documentation

8.99.4.1 rx'tpu'deinit()

rx_err_t rx_tpu_deinit (
 const [rx_tpu_channel_t](#) channel) [nodiscard]

Deinitialize TPU channel.

Stops the channel counter, resets mode to normal, and marks the channel as uninitialized. Does NOT disable the TPU module clock (other channels may still be active).

Parameters

in	channel	TPU channel (1, 2, 4, or 5)
----	---------	-----------------------------

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Success, channel released
<code>k_rx_err_invalid_arg</code>	Invalid channel

Precondition

Channel was previously initialized

Postcondition

Counter stopped and zeroed
Mode register reset to normal operation
Channel marked as uninitialized

Note

Thread Safety: Not thread-safe, call during shutdown only

See also

[rx_tpu_init_phase_count\(\)](#) Re-initialize after deinit

Since

Version 1.0.0

Deinitialize TPU channel.

Performs an orderly shutdown of the specified TPU channel:

1. Validate channel and get array index
2. Stop counter (clear CSTn in TSTR)
3. Reset TMDR to normal operation mode (0x00)
4. Disable all interrupts (TIER = 0x40; bit 6 reserved/must-write-1)
5. Clear counter (TCNT = 0)
6. Mark channel as uninitialized in `s_tpu_initialized[]`

This function does NOT disable the TPU module clock (MSTPCRA.MSTPA13), as other channels may still be in use.

Precondition

channel must be a valid phase-counting TPU channel (1, 2, 4, or 5)
 Motor driven by this encoder must be stopped before calling

Postcondition

Counter stopped and zeroed
 TMDR reset to normal mode
 s_tpu_initialized[idx] == false

Note

Not thread-safe: do not access channel concurrently during deinit
 Channel may be partially initialized; deinit succeeds regardless

```
rx_err_t err = rx_tpu_deinit(k_tpu_channel_1);
```

See also

[rx_tpu_init_phase_count\(\)](#) Re-initialize after deinit
[rx_tpu_stop\(\)](#) Stop counter without full teardown

Since

Version 1.0.0

Definition at line 777 of file [rx_tpu.c](#).

Here is the call graph for this function:

8.99.4.2 rx_tpu_init_phase_count()

```
rx_err_t rx_tpu_init_phase_count (
    const rx_tpu_config_t * config) [nodiscard]
```

Initialize TPU channel for phase counting mode.

Configures a TPU channel for hardware quadrature encoder phase counting. This function:

1. Enables the TPU module (clears MSTPA13)
2. Stops the channel counter
3. Sets phase counting mode in TMDR
4. Clears the counter to zero
5. Enables overflow/underflow interrupts (if needed later)

After initialization, call [rx_tpu_start\(\)](#) to begin counting.

Parameters

in	config	Phase counting configuration
----	--------	------------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, channel configured
k_rx_err_null_ptr	config is nullptr
k_rx_err_invalid_arg	Invalid channel (not 1/2/4/5); Invalid phase mode (not 1-4)

<code>k_rx_err_invalid_state</code>	Channel already initialized
-------------------------------------	-----------------------------

Precondition

TPU module clock enabled (or function enables it)
External clock pins (TCLKA-D) configured as peripheral I/O

Postcondition

Channel configured in phase counting mode
Counter cleared to zero
Counter NOT started (call [rx_tpu_start\(\)](#))

Note

Thread Safety: Not thread-safe, call during init only

See also

[rx_tpu_start\(\)](#) Start counting after init
[rx_tpu_deinit\(\)](#) Release channel resources

Since

Version 1.0.0

Implementation of [rx_tpu_init_phase_count\(\)](#) - see [rx_tpu.h](#) for complete API documentation.

Register Configuration Sequence

1. Unlock PRCR, clear MSTPCRA.MSTPA13, lock PRCR
2. Clear CSTn in TSTR (stop counter)
3. Write phase counting mode to TMDR.MD
4. Write 0x00 to TCR (free-running, external clock)
5. Write 0x00 to TIER (no interrupts)
6. Write 0x0000 to TCNT (clear counter)

Here is the call graph for this function:

8.99.4.3 rx`tpu`read`count()

```

rx_err_t rx_tpu_read_count (
    const rx_tpu_channel_t channel,
    uint16_t * count) [nodiscard]

```

Read TPU channel 16-bit counter value.

Reads the current TCNT register value. In phase counting mode this is an up/down counter that tracks encoder position modulo 65536.

Parameters

in	channel	TPU channel (1, 2, 4, or 5)
out	count	Pointer to store 16-bit counter value (0-65535)

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, count written
k_rx_err_null_ptr	count is nullptr
k_rx_err_invalid_arg	Invalid channel
k_rx_err_invalid_state	Channel not initialized

Precondition

Channel initialized and running

Postcondition

count contains current TCNT value

Note

Thread Safety: Safe - single volatile register read

See also

[rx_tpu_read_direction\(\)](#) Read counting direction

Since

Version 1.0.0

Read TPU channel 16-bit counter value.

Performs a single volatile read of the TCNT register for the specified channel. In 4x phase counting mode, the counter increments or decrements on every edge of both A and B encoder channels.

Precondition

Channel must be initialized via [rx_tpu_init_phase_count\(\)](#)
count must point to valid uint16_t storage

Postcondition

*count contains the TCNT register value at the time of the read
Hardware registers unchanged

Note

Not thread-safe: counter may wrap between multiple reads
Wraps naturally at 0 and 65535 (16-bit overflow)

```
uint16_t count;  
rx_err_t err = rx_tpu_read_count(k_tpu_channel_1, &count);
```

See also

Here is the call graph for this function:

8.99.4.4 rx_tpu_read_direction()

```

rx_err_t rx_tpu_read_direction (
    const rx_tpu_channel_t channel,
    bool * counting_up) [nodiscard]

```

Read TPU channel counting direction.

Reads the TCFD bit in the TSR register to determine whether the counter is currently counting up (forward) or down (reverse).

Parameters

in	channel	TPU channel (1, 2, 4, or 5)
----	---------	-----------------------------

out	counting_up	Pointer to store direction flag (true = counting up/forward, false = counting down/reverse)
-----	-------------	---

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, direction written
k_rx_err_null_ptr	counting_up is nullptr
k_rx_err_invalid_arg	Invalid channel
k_rx_err_invalid_state	Channel not initialized

Precondition

Channel initialized and running in phase counting mode

Postcondition

counting_up reflects TSR.TCFD bit state

Note

Thread Safety: Safe - single volatile register read

See also

[rx_tpu_read_count\(\)](#) Read counter value

Since

Version 1.0.0

Read TPU channel counting direction.

Reads the Timer Counter Flag Direction (TCFD) bit in the TSR register. TCFD reflects the last count event direction:

- TCFD = 1: Counter incremented on the last edge (counting up / forward)
- TCFD = 0: Counter decremented on the last edge (counting down / reverse)

Precondition

Channel must be initialized via [rx_tpu_init_phase_count\(\)](#)

counting_up must point to valid bool storage

Postcondition

*counting_up reflects TSR.TCFD at the time of the read
Hardware registers unchanged

Note

Not thread-safe: value may change between reads if encoder is moving
Direction is unreliable if counter is stationary (no recent edge)

```
bool forward;
rx_err_t err = rx_tpu_read_direction(k_tpu_channel_1, &forward);
```

Here is the call graph for this function:

8.99.4.5 rx_tpu_reset_count()

```
rx_err_t rx_tpu_reset_count (  
    const rx_tpu_channel_t channel)  [nodiscard]
```

Reset TPU channel counter to zero.

Writes zero to the TCNT register. Should be called while the counter is stopped for reliable operation, though the hardware permits writing TCNT while running.

Parameters

in	channel	TPU channel (1, 2, 4, or 5)
----	---------	-----------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, counter zeroed
k_rx_err_invalid_arg	Invalid channel
k_rx_err_invalid_state	Channel not initialized

Precondition

Channel initialized

Postcondition

TCNT = 0

Note

Thread Safety: Not thread-safe (read-modify-write possible issues)

Since

Version 1.0.0

Reset TPU channel counter to zero.

Writes k_tpu_tcnt_zero (0x0000) to the TCNT register, resetting the encoder position counter. The counter continues running from the new zero baseline.

Typical use: zero encoder position at a known reference point (home).

Precondition

Channel must be initialized via [rx_tpu_init_phase_count\(\)](#)

Channel should be stopped ([rx_tpu_stop\(\)](#)) before resetting for atomic 0

Postcondition

TCNT register written to 0x0000

Counter resumes from zero if running

Note

Not thread-safe: write races with live counter updates from encoder

May cause a single spurious velocity estimate if called while running

```
rx_tpu_stop(k_tpu_channel_1);
rx_tpu_reset_count(k_tpu_channel_1);
rx_tpu_start(k_tpu_channel_1);
```

Here is the call graph for this function:

8.99.4.6 rx_tpu_start()

```
rx_err_t rx_tpu_start (  
    const rx_tpu_channel_t channel)  [nodiscard]
```

Start TPU channel counter.

Sets the CSTn bit in TSTR to begin counter operation. In phase counting mode, the counter increments/decrements based on the external clock phase relationship.

Parameters

in	channel	TPU channel (1, 2, 4, or 5)
----	---------	-----------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, counter started
k_rx_err_invalid_arg	Invalid channel
k_rx_err_invalid_state	Channel not initialized

Precondition

Channel initialized via [rx_tpu_init_phase_count\(\)](#)

Postcondition

CSTn bit set, counter running

Note

Thread Safety: Safe from any context (atomic register write)

See also

[rx_tpu_stop\(\)](#) Stop counter

Since

Version 1.0.0

Start TPU channel counter.

Sets the Count Start (CSTn) bit in the TSTR register to begin counter operation. Once started, the TCNT register increments or decrements on each external encoder clock edge according to the configured phase mode.

Precondition

Channel must be initialized via [rx_tpu_init_phase_count\(\)](#)
 External encoder clock pins must be connected and valid

Postcondition

TSTR.CSTn bit set, counter begins counting encoder pulses
 TCNT updates in real time from encoder edges

Note

Not thread-safe: modifies shared TSTR register
 Idempotent: safe to call when already running

```
rx_err_t err = rx_tpu_start(k_tpu_channel_1);
```

8.99.4.7 rx_tpu_stop()

```
rx_err_t rx_tpu_stop (  
    const rx_tpu_channel_t channel)  [nodiscard]
```

Stop TPU channel counter.

Clears the CSTn bit in TSTR to stop counter operation. The counter value is preserved.

Parameters

in	channel	TPU channel (1, 2, 4, or 5)
----	---------	-----------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, counter stopped
k_rx_err_invalid_arg	Invalid channel
k_rx_err_invalid_state	Channel not initialized

Precondition

Channel initialized

Postcondition

CSTn bit cleared, counter stopped

Counter value preserved

Note

Thread Safety: Safe from any context (atomic register write)

See also

[rx_tpu_start\(\)](#) Restart counter

Since

Version 1.0.0

Stop TPU channel counter.

Clears the Count Start (CSTn) bit in the TSTR register to halt counter operation. The TCNT value is preserved and encoder edges no longer update it. The channel remains initialized and can be restarted with [rx_tpu_start\(\)](#).

Precondition

Channel must be initialized via [rx_tpu_init_phase_count\(\)](#)
 TSTR register must be accessible (module clock enabled)

Postcondition

TSTR.CSTn bit cleared, counter halted
 TCNT value preserved at last count

Note

Not thread-safe: modifies shared TSTR register
 Idempotent: safe to call when already stopped

```
rx_err_t err = rx_tpu_stop(k_tpu_channel_1);
```

00002  * @file rx_tpu.h
00003  * @brief TPU HAL Driver for RX72N 16-Bit Timer Pulse Unit (Phase Counting)
00004  *
00005  * @details
00006  * Hardware abstraction layer for the RX72N TPU peripheral, focused on
00007  * phase counting mode for quadrature encoder input. This driver provides
00008  * low-level channel configuration, counter access, and direction reading.
00009  *
00010  * ## STAR Project Usage
00011  *
00012  * The TPU is used for rear wheel encoder decoding. Front wheels use the MTU
00013  * peripheral (see rx_mtu.h / rx_mtu_encoder.h).
00014  *
00015  * | Encoder | Peripheral | Channel | Phase A Pin | Phase B Pin |
00016  * |-----|-----|-----|-----|-----|
00017  * | 0 (FL) | MTU1 | MTU1 | P24/MTCLKA (pin 33) | P25/MTCLKB (pin 32) |
00018  * | 1 (FR) | MTU2 | MTU2 | PA1/MTCLKC (pin 96) | PC5/MTCLKD (pin 62) |
00019  * | 2 (BR) | TPU1 | TPU1 | PC2/TCLKA (pin 70) | PA3/TCLKB (pin 94) |
00020  * | 3 (BL) | TPU2 | TPU2 | PC0/TCLKC (pin 75) | PB3/TCLKD (pin 82) |
00021  *
00022  * ## Architecture
00023  *
00024  * ```
00025  * Application Layer: motor_control_task.c (250 Hz PID loop)
00026  * |
00027  * Encoder Layer: rx_encoder_tpu.c (overflow handling, velocity)
00028  * |
00029  * HAL Layer: rx_tpu.h/c (THIS MODULE - register access)
00030  * |
00031  * Register Layer: rx72n_tpu_regs.h (memory-mapped I/O)
00032  * ```
00033  *
00034  * ## Key Features
00035  *
00036  * - Phase counting mode 4 (4x resolution, all edges)
00037  * - 16-bit up/down counter with direction flag
00038  * - Hardware noise filter on input pins
00039  * - Module stop control for power management
00040  *
00041  * @par Performance
00042  * | Operation | Time | Notes |
00043  * |-----|-----|-----|
00044  * | rx_tpu_init_phase() | ~20 us | One-time setup |
00045  * | rx_tpu_read_count() | ~0.5 us | Single register read |

Enumerations

- enum `adc_constants_t` : `uint8_t` { `k_adc_max_units` = 2 , `k_adc_max_channels` = 8 , `k_adc_timeout_ms` = 100 }
ADC hardware configuration limits.
- enum `adc_bit_constants_t` : `uint8_t` { `k_adc_bit_one` = 1U }
Bit manipulation constants for ADC register operations.
- enum `adc_module_stop_bits_t` : `uint8_t` { `k_adc_mstpra_s12ad1` = 16 , `k_adc_mstpra_s12ad0` = 17 }
ADC module stop bit positions in MSTPCRA register.

- enum `adc_adcer_bits_t` : `uint16_t` {
`k_adc_adcer_adprc_mask` , `k_adc_adcer_adprc_shift` = 1U , `k_adc_adcer_adprc_12bit` = 0U
, `k_adc_adcer_adprc_10bit` = 1U ,
`k_adc_adcer_adprc_8bit` = 2U }
- ADC Control Extended Register (ADCER) bit definitions.
- enum `adc_adcsr_bits_t` : `uint16_t` { `k_adc_adcsr_idle` = 0U , `k_adc_adcsr_adst` = 32768U }
- ADC Control/Status Register (ADCSR) bit definitions.
- enum `adc_channel_boundaries_t` : `uint8_t` { `k_adc_channel_adansa0_max` = 15 ,
`k_adc_channel_adansa1_base` = 16 }
- ADC channel selection register boundaries.
- enum `adc_misc_constants_t` : `uint16_t` { `k_adc_timeout_multiplier` = 1000 , `k_adc_timeout_expired`
= 0 , `k_adc_reference_voltage_mv` = 3300 }
- ADC timeout and voltage reference constants.
- enum `adc_raw_value_t` : `uint16_t` { `k_adc_raw_value_reset` = 0 }
- Raw ADC value reset/default constants.

Functions

- static volatile `rx_s12ad_regs_t` * `internal_get_adc_base` (const `uint8_t` unit)
- Get ADC register base address from unit number.
- static `rx_err_t` `internal_configure_adc_unit` (const `uint8_t` unit, volatile `rx_s12ad_regs_t` *adc,
const `uint8_t` bits)
- Configure ADC unit control registers and enable module clock.
- static `rx_err_t` `internal_validate_unit_channel` (const `uint8_t` unit, `uint8_t` channel)
- Validate ADC unit and channel numbers.
- static `rx_err_t` `internal_read_channel_value` (volatile `rx_s12ad_regs_t` *adc, const `adc_channel_t`
channel, `uint16_t` *value)
- Read raw ADC value from a specific channel data register.
- `rx_err_t` `adc_init` (const `adc_unit_t` unit, const `adc_channel_t` channel, const `adc_resolution_t`
bits)
- Initialize ADC unit and enable a specific channel.
- `rx_err_t` `adc_read` (const `adc_unit_t` unit, const `adc_channel_t` channel, `uint16_t` *value)
- Read raw ADC conversion value from specified channel.
- `rx_err_t` `adc_read_voltage_mv` (const `adc_unit_t` unit, `adc_channel_t` channel, `adc_resolution_t`
bits, `uint32_t` *voltage_mv)
- Read ADC value and convert to millivolts.

Variables

- static const char *const `s_tag` = "ADC"
- Log tag for ADC module messages.
- static bool `s_adc_unit_initialized` [`k_adc_max_units`] = {false, false}
- Tracks initialization state for each ADC unit.
- static `adc_resolution_t` `s_adc_unit_resolution` [`k_adc_max_units`]
- Stores configured resolution for each ADC unit.

8.101.1 Detailed Description

ADC Driver for RX72N S12ADFa - 12-bit Analog-to-Digital Conversion.

8.101.1.1 Overview

This file provides the hardware abstraction layer (HAL) for the S12ADFa (12-bit Analog-to-Digital Converter) peripheral on the Renesas RX72N microcontroller. The S12ADFa supports dual ADC units with 8 channels each, configurable resolution (8/10/12-bit), and single-scan conversion mode.

8.101.1.2 Hardware Architecture

8.101.1.3 S12ADFa Features Used

Feature	Status	Notes
Dual ADC units (S12AD0, S12AD1)	↔ [OK]↔	Both supported
12/10/8-bit resolution	↔ [OK]↔	Configurable per unit
Single-scan mode	↔ [OK]↔	Software-triggered
Continuous scan mode	↔ [X]↔	Not implemented
Group scan mode	↔ [X]↔	Not implemented
A/D interrupts	↔ [X]↔	Polling only
Self-diagnosis	↔ [X]↔	Not implemented

Feature	Status	Notes
Double trigger	↔ [X]↔	Not implemented

8.101.1.4 Register Access Pattern

8.101.1.5 Conversion Timing

Resolution	Conversion Time	Sample Rate (max)
12-bit	~1.0 us	~1 MHz
10-bit	~0.9 us	~1.1 MHz
8-bit	~0.8 us	~1.25 MHz

Note: Times are approximate at PCLKB = 60 MHz.

8.101.1.6 Voltage Calculation

The `adc_read_voltage_mv()` function converts raw ADC values to millivolts:

$$V_{mV} = \frac{V_{raw} \times V_{ref}}{2^{bits} - 1}$$

Where:

- V_{raw} = Raw ADC value (0 to $2^{bits}-1$)
- V_{ref} = Reference voltage (3300 mV)
- $bits$ = Resolution (8, 10, or 12)

8.101.1.7 Thread Safety

Function	Thread-Safe	Notes
adc_init()	No	Call during initialization only
adc_read()	No	Caller must synchronize
adc_read_voltage_mv()	No	Caller must synchronize

Each ADC unit can be accessed independently, but concurrent access to the same unit requires external synchronization.

8.101.1.8 Memory Usage

Section	Size	Contents
.text	~800 bytes	Function code
.rodata	~80 bytes	Log strings, tag
.bss	6 bytes	s_adc_unit_initialized[2], s_adc_unit_resolution[2]

8.101.1.9 NASA Power of 10 Compliance

Rule	Status	Implementation
1. Simplify control flow	↔ [OK]↔	No goto, setjmp, recursion
2. Fixed loop bounds	↔ [OK]↔	Timeout loop has fixed maximum
3. No dynamic memory	↔ [OK]↔	Static arrays only
4. Functions < 60 lines	↔ [OK]↔	Helper functions for decomposition
5. Use assertions	↔ [OK]↔	RX_CHECK_NULL_PTR, RX_CHECK_RANGE_TAG
6. Data at smallest scope	↔ [OK]↔	Local variables, static helpers
7. Check return values	↔ [OK]↔	RX_RETURN_ON_ERROR macro
8. Limit preprocessor	↔ [OK]↔	Only includes

Rule	Status	Implementation
9. Restrict pointers	↔ [OK]↔	Hardware register pointers only
10. Compile warnings	↔ [OK]↔	-Wall -Wextra -Werror clean

8.101.2 Enumeration Type Documentation

8.101.2.1 adc`adcer`bits`t

```
enum adc\_adcer\_bits\_t : uint16_t
```

ADC Control Extended Register (ADCER) bit definitions.

Defines the bit fields for the ADCER (A/D Control Extended Register) which controls ADC resolution and data format. The ADPRC field (bits 1:0) sets the A/D conversion resolution.

8.101.2.2 ADCER Register Layout (bits 1:0 - ADPRC)

ADPRC[2:↵ 1]	Resolution	Max Value	Conversion Time
00	12-bit	4095	~1.0 us
01	10-bit	1023	~0.9 us
10	8-bit	255	~0.8 us
11	Reserved	-	-

See also

[internal_configure_adc_unit\(\)](#) Uses these to set resolution

Since

Version 1.0.0

Enumerator

k_adc_adcer_adprc_mask	ADPRC field mask (2-bit, unshifted) per RX72N HW manual R01↵UH0824EJ0111 Section 56.2.13
k_adc_adcer_adprc_shift	ADPRC field bit position: bits 2:1 of ADCER
k_adc_adcer_adprc_12bit	ADPRC = 00: 12-bit resolution (default)
k_adc_adcer_adprc_10bit	ADPRC = 01: 10-bit resolution
k_adc_adcer_adprc_8bit	ADPRC = 10: 8-bit resolution

Definition at line 252 of file [adc.c](#).

```

00252     : uint16_t {
00253     k_adc_adcer_adprc_mask =
00254     3U, /**< ADPRC field mask (2-bit, unshifted) per RX72N HW manual R01UH0824EJ0111 Section 56.2.13 */
00255     k_adc_adcer_adprc_shift = 1U, /**< ADPRC field bit position: bits 2:1 of ADCER */
00256     k_adc_adcer_adprc_12bit = 0U, /**< ADPRC = 00: 12-bit resolution (default) */
00257     k_adc_adcer_adprc_10bit = 1U, /**< ADPRC = 01: 10-bit resolution */
00258     k_adc_adcer_adprc_8bit  = 2U, /**< ADPRC = 10: 8-bit resolution */
00259 } adc_adcer_bits_t;

```

8.101.2.3 adc`adcsr`bits`t

```
enum adc\_adcsr\_bits\_t : uint16_t
```

ADC Control/Status Register (ADCSR) bit definitions.

Defines bit values for the ADCSR (A/D Control Status Register) which controls conversion start and indicates conversion status.

8.101.2.4 ADCSR Bit 15 (ADST) - A/D Conversion Start

Value	Read Meaning	Write Meaning
0	Conversion stopped/complete	(No effect)
1	Conversion in progress	Start conversion

See also

[adc_read\(\)](#) Uses ADST to trigger and poll conversion

Since

Version 1.0.0

Enumerator

k_adc_adcsr_idle	Idle state: ADST=0 (conversion complete)
k_adc_adcsr_adst	Start bit: ADST=1 (bit 15 = 0x8000 = 32768)

Definition at line 280 of file [adc.c](#).

```
00280      : uint16_t {
00281  k_adc_adcsr_idle = 0U,    /**< Idle state: ADST=0 (conversion complete) */
00282  k_adc_adcsr_adst = 32768U, /**< Start bit: ADST=1 (bit 15 = 0x8000 = 32768) */
00283 } adc_adcsr_bits_t;
```

8.101.2.5 adc`bit`constants`

```
enum adc\_bit\_constants\_t : uint8_t
```

Bit manipulation constants for ADC register operations.

Single-bit value used for shift operations when setting/clearing individual bits in ADC control and channel selection registers.

Since

Version 1.0.0

Enumerator

k_adc_bit_one	Single-bit value for shift operations (1 << n)
---------------	--

Definition at line 197 of file [adc.c](#).

```
00197      : uint8_t {
00198  k_adc_bit_one = 1U, /**< Single-bit value for shift operations (1 « n) */
00199 } adc_bit_constants_t;
```

8.101.2.6 adc`channel`boundaries`t

enum [adc_channel_boundaries_t](#) : uint8_t

ADC channel selection register boundaries.

Defines the channel boundaries for ADANSA0 and ADANSA1 registers. Channels 0-15 are selected via ADANSA0, channels 16+ via ADANSA1.

For S12AD0: Physical channels AN0-AN7 (channels 0-7) For S12AD1: Physical channels AN16-AN23 (channels 0-7 mapped)

See also

[adc_init\(\)](#) Uses these for channel enable logic

Since

Version 1.0.0

Enumerator

k_adc_channel_adansa0_max	Maximum channel for ADANSA0 register
k_adc_channel_adansa1_base	Base channel for ADANSA1 register

Definition at line 300 of file [adc.c](#).

```
00300      : uint8_t {
00301  k_adc_channel_adansa0_max = 15, /**< Maximum channel for ADANSA0 register */
00302  k_adc_channel_adansa1_base = 16, /**< Base channel for ADANSA1 register */
00303 } adc_channel_boundaries_t;
```

8.101.2.7 adc`constants`t

enum [adc_constants_t](#) : uint8_t

ADC hardware configuration limits.

Defines the hardware limits and configuration constants for the S12ADFa peripheral on the RX72N microcontroller. These values are derived from the RX72N hardware manual Chapter 41 (S12ADFa).

See also

[internal_get_adc_base\(\)](#) Uses [k_adc_max_units](#) for validation

[s_adc_unit_initialized](#) Array sized by [k_adc_max_units](#)

Since

Version 1.0.0

Enumerator

k_adc_max_units	Number of ADC units (S12AD0, S12AD1)
k_adc_max_channels	Channels per unit (0-7 for S12AD0, 16-23 for S12AD1)
k_adc_timeout_ms	Maximum wait time for conversion completion (ms)

Definition at line 181 of file [adc.c](#).

```
00181      : uint8_t {
00182  k_adc_max_units    = 2,  /**< Number of ADC units (S12AD0, S12AD1) */
00183  k_adc_max_channels = 8,  /**< Channels per unit (0-7 for S12AD0, 16-23 for S12AD1) */
00184  k_adc_timeout_ms   = 100, /**< Maximum wait time for conversion completion (ms) */
00185 } adc_constants_t;
```

8.101.2.8 adc`misc`constants`t

enum [adc_misc_constants_t](#) : uint16_t

ADC timeout and voltage reference constants.

Miscellaneous constants for timeout handling and voltage calculations.

8.101.2.9 Timeout Calculation

Total timeout iterations = k_adc_timeout_ms * k_adc_timeout_multiplier = 100 * 1000 = 100,000 iterations

At ~10 cycles per iteration, this provides ~4ms timeout at 240 MHz.

8.101.2.10 Voltage Reference

The RX72N STAR board uses 3.3V as the ADC reference voltage (AVCC). The k_adc_reference_voltage_mv constant (3300 mV) is used in the voltage calculation formula.

See also

[adc_read\(\)](#) Uses timeout constants

[adc_read_voltage_mv\(\)](#) Uses reference voltage

Since

Version 1.0.0

Enumerator

k_adc_timeout_multiplier	Loop iterations per ms of timeout
--------------------------	-----------------------------------

k_adc_timeout_expired	Sentinel value: timeout counter reached zero
k_adc_reference_voltage_mv	ADC reference voltage: 3.3V = 3300 mV

Definition at line 332 of file [adc.c](#).

```
00332      : uint16_t {
00333   k_adc_timeout_multiplier = 1000, /**< Loop iterations per ms of timeout */
00334   k_adc_timeout_expired    = 0,    /**< Sentinel value: timeout counter reached zero */
00335   k_adc_reference_voltage_mv = 3300, /**< ADC reference voltage: 3.3V = 3300 mV */
00336 } adc_misc_constants_t;
```

8.101.2.11 adc`module`stop`bits`

```
enum adc_module_stop_bits_t : uint8_t
```

ADC module stop bit positions in MSTPCRA register.

Defines the bit positions in the MSTPCRA (Module Stop Control Register A) that control the clock supply to the S12AD0 and S12AD1 modules. These bits must be cleared (clock enabled) before accessing ADC registers.

8.101.2.12 Module Stop Control

Bit	Module	0 = Clock Enabled	1 = Clock Stopped
17	S12AD0	ADC unit 0 active	ADC unit 0 stopped
16	S12AD1	ADC unit 1 active	ADC unit 1 stopped

Note

Accessing ADC registers while module clock is stopped causes bus error
PRCR register must be unlocked before modifying MSTPCRA

```
00225      : uint8_t {
00226   k_adc_mstpra_s12ad1 = 16, /**< MSTPCRA bit 16: S12AD1 module stop control */
00227   k_adc_mstpra_s12ad0 = 17, /**< MSTPCRA bit 17: S12AD0 module stop control */
00228 } adc_module_stop_bits_t;
```

8.101.2.13 adc`raw`value`t

```
enum adc\_raw\_value\_t : uint16_t
```

Raw ADC value reset/default constants.

Default raw value used to initialize the raw_value variable before a conversion result is written. Using a named constant makes the intent explicit and avoids magic numeric literals.

Since

Version 1.0.0

Enumerator

k_adc_raw_value_reset	Reset/default raw ADC value before conversion
---------------------------------------	---

Definition at line [351](#) of file [adc.c](#).

```
00351      : uint16_t {
00352   k_adc_raw_value_reset = 0, /**< Reset/default raw ADC value before conversion */
00353 } adc_raw_value_t;
```

8.101.3 Function Documentation

8.101.3.1 adc`init`()

```
rx_err_t adc_init (
    const adc\_unit\_t unit,
    const adc\_channel\_t channel,
    const adc\_resolution\_t bits) [nodiscard]
```

Initialize ADC unit and enable a specific channel.

Initialize ADC unit and channel.

Configures the S12ADFa peripheral for A/D conversion. On first call for each unit, enables the module clock, configures resolution, and initializes the hardware. Subsequent calls to the same unit enable additional channels.

8.101.3.2 Initialization Behavior

Scenario	Action	Resolution	Result
First init for unit	Full init	Set to 'bits'	k_rx_ok
Subsequent init, same bits	Enable channel only	Unchanged	k_rx_ok

Scenario	Action	Resolution	Result
Subsequent init, different bits	Error	Unchanged	k_rx_err_invalid_arg

Precondition

- None (can be first call for unit)
- Resolution must match if unit already initialized

Postcondition

- Module clock enabled (if first init)
- Channel enabled in ADANSA register
- Unit marked as initialized

Note

- NOT thread-safe: Call from initialization code only
- Performance: $\sim 1\text{-}2$ us for first init, ~ 0.5 us for subsequent

Example:

```
// Initialize ADC unit 0, channel 2 with 12-bit resolution
rx_err_t err = adc_init(k_adc_unit_0, k_adc_channel_2, k_adc_resolution_12bit);
if (err != k_rx_ok) {
    rx_log_error("SENSOR", "ADC init failed: %d", err);
    return err;
}
```

Here is the call graph for this function:

8.101.3.3 adc`read()

```

rx_err_t adc_read (
    const adc_unit_t unit,
    const adc_channel_t channel,
    uint16_t * value) [nodiscard]

```

Read raw ADC conversion value from specified channel.

Read ADC value.

Performs a single-scan A/D conversion and returns the raw digital value. This is a blocking operation that polls the ADST bit until conversion completes or timeout occurs.

8.101.3.4 Conversion Sequence

1. Validate parameters and initialization state
2. Start conversion by setting ADCSR.ADST bit
3. Poll ADCSR.ADST until cleared (conversion complete)
4. Read result from appropriate ADDRn register

8.101.3.5 Output Value Ranges

Resolution	Range	Full-Scale
12-bit	0-4095	3.3V
10-bit	0-1023	3.3V
8-bit	0-255	3.3V

Precondition

ADC unit must be initialized via `adc_init()`
value must point to valid `uint16_t` storage

Postcondition

*value contains raw ADC reading (if `k_rx_ok`)
ADC ready for next conversion

Note

NOT thread-safe: Caller must synchronize if shared
Blocking: Waits up to ~100ms for conversion
Performance: ~1-10 us typical (depends on conversion time)

Warning

Do not call from ISR (blocking wait)

Example:

```
uint16_t raw_value;  
rx_err_t err = adc_read(k_adc_unit_0, k_adc_channel_2, &raw_value);  
if (err == k_rx_ok) {  
    // Example: 12-bit resolution (0-4095 raw -> 0-3.3 V)  
    static const float s_vref_volts = 3.3F;  
    static const float s_adc_full_scale_12bit = 4095.0F;  
    float voltage_v = (raw_value * s_vref_volts) / s_adc_full_scale_12bit;  
}
```

Here is the call graph for this function:

Here is the caller graph for this function:

8.101.3.6 adc_read_voltage_mv()

```

rx_err_t adc_read_voltage_mv (
    const adc_unit_t unit,
    adc_channel_t channel,
    adc_resolution_t bits,
    uint32_t * voltage_mv) [nodiscard]
  
```

Read ADC value and convert to millivolts.

Performs an A/D conversion and scales the result to millivolts. This is a convenience function that calls [adc_read\(\)](#) and applies the voltage calculation formula.

8.101.3.7 Voltage Calculation Formula

$$V_{mV} = \frac{V_{raw} \times 3300}{2^{bits} - 1}$$

8.101.3.8 Example Calculations

Resolution	Raw Value	Voltage (mV)	Calculation
12-bit	2048	1650	2048 x 3300 / 4095
10-bit	512	1650	512 x 3300 / 1023
8-bit	128	1655	128 x 3300 / 255

Precondition

ADC unit must be initialized via [adc_init\(\)](#)
 bits must match the resolution used in [adc_init\(\)](#)

Postcondition

*voltage_mv contains voltage in millivolts (0-3300)
 ADC ready for next conversion

Note

NOT thread-safe: Caller must synchronize if shared

Blocking: Waits for conversion (see `adc_read`)

Reference: Uses 3.3V reference (`k_adc_reference_voltage_mv = 3300`)

Example:

```
// Read motor current sense (DRV8263H IPROPI output)
uint32_t voltage_mv;
rx_err_t err = adc_read_voltage_mv(k_adc_unit_0, k_adc_channel_0,
                                   k_adc_resolution_12bit, &voltage_mv);
if (err == k_rx_ok) {
    // voltage_mv: 0-3300 mV
    // For DRV8263H-Q1 IPROPI (202 uA/A mirror, 5100 Ohm sense):
    // I_motor = V_IPROPI / k_ipropi_divisor
    // (where k_ipropi_divisor = 1.0302 = 202e-6 * 5100)
    // Fixed-point: scale = 10000, divisor = 10302 (1.0302 * 10000)
    enum : uint32_t { k_scale = 10000, k_divisor = 10302 };
    uint32_t current_ma = (voltage_mv * k_scale) / k_divisor;
    rx_log_info("ADC", "Current: %lu mA", current_ma);
}
```

Here is the call graph for this function:

8.101.3.9 internal_configure_adc_unit()

```

rx_err_t internal_configure_adc_unit (
    const uint8_t unit,
    volatile rx_s12ad_regs_t * adc,
    const uint8_t bits) [static]
  
```

Configure ADC unit control registers and enable module clock.

Performs one-time initialization of an ADC unit:

1. Unlocks PRCR to allow MSTPCRA modification
2. Clears module stop bit in MSTPCRA (enables clock)
3. Locks PRCR
4. Configures ADCER register for desired resolution
5. Marks unit as initialized

8.101.3.10 Register Modification Sequence

```

PRCR = k_rx_prcr_unlock_prc1_prc3 // Enable MSTPCRA write
MSTPCRA &= ~(1 « module_stop_bit) // Clear module stop bit
PRCR = k_rx_prcr_lock // Disable protected writes
ADCER = (ADCER & ~mask) | resolution_bits // Set resolution
  
```

Precondition

adc must be valid pointer from [internal_get_adc_base\(\)](#)

Unit must not already be initialized

Postcondition

Module clock enabled (MSTPCRA bit cleared)

ADCER configured with requested resolution

s_adc_unit_initialized[unit] = true

Note

NOT thread-safe: Protected register access

Performance: ~1 us @ 240 MHz

PRCR unlock window is minimized

Warning

Must not be called while ADC is converting
 PRCR access requires proper unlock sequence

8.101.3.11 internal_get_adc_base()

```
volatile rx\_s12ad\_regs\_t * internal_get_adc_base (
    const uint8_t unit)  [static]
```

Get ADC register base address from unit number.

Returns a pointer to the register structure for the specified ADC unit. The RX72N has two ADC units with registers at different base addresses:

Unit	Peripheral	Base Address
0	S12AD0	0x00089000
1	S12AD1	0x00089100

Precondition

None (pure lookup function)

Postcondition

No state changes

Note

Thread-safe: Pure function with no shared state

Performance: O(1), ~10 cycles

```

Read raw ADC value from a specific channel data register.

Helper function that reads the conversion result from the appropriate ADDRn register based on channel number. Extracted from [adc_read\(\)](#) to support NASA Power of 10 Rule 4 (functions under 60 lines).

8.101.3.13 Channel to Register Mapping

Channel	Register	Offset
0	ADDR0	0x020
1	ADDR1	0x022
2	ADDR2	0x024
3	ADDR3	0x026
4	ADDR4	0x028
5	ADDR5	0x02A
6	ADDR6	0x02C
7	ADDR7	0x02E

Precondition

adc must be valid pointer from [internal_get_adc_base\(\)](#)

ADC conversion must be complete (ADST bit cleared)

Postcondition

*value contains raw ADC reading (12/10/8-bit depending on config)

No hardware state changes

Note

Thread-safe: Read-only register access

Performance: O(1), ~30 cycles

8.101.3.14 internal_validate_unit_channel()

```

rx_err_t internal_validate_unit_channel (
    const uint8_t unit,
    uint8_t channel) [static]

```

Validate ADC unit and channel numbers.

Performs range validation for ADC unit and channel parameters before any hardware access. This prevents undefined behavior from invalid register access.

8.101.3.15 Validation Rules

Parameter	Valid Range	Error Code
unit	0-1 (k_adc_unit_0 to k_adc_unit_1)	k_rx_err_invalid_arg
channel	0-7 (k_adc_channel_0 to k_adc_channel_7)	k_rx_err_invalid_arg

Precondition

None (pure validation function)

Postcondition

No state changes

Note

Thread-safe: Pure function with no shared state

Performance: $O(1)$, ~ 20 cycles

Logs error message on validation failure

8.101.4 Variable Documentation

8.101.4.1 s`adc`unit`initialized

`bool s_adc_unit_initialized[k_adc_max_units] = {false, false}` [static]

Tracks initialization state for each ADC unit.

Array indexed by ADC unit number (0 or 1). Set to true when `adc_init()` successfully initializes the unit. Used to prevent double-initialization and to validate that a unit is ready before reading.

Index	Unit	Default
0	S12AD0	false
1	S12AD1	false

Warning

NOT thread-safe - initialization should be done from single thread

See also

`adc_init()` Sets to true on successful initialization

`adc_read()` Checks before allowing read operation

Definition at line 386 of file `adc.c`.

00386 {false, false};

Referenced by `adc_init()`, `adc_read()`, and `internal_configure_adc_unit()`.

8.101.4.2 s`adc`unit`resolution

`adc_resolution_t s_adc_unit_resolution[k_adc_max_units]` [static]

Initial value:

= {k_adc_resolution_12bit,
k_adc_resolution_12bit}

Stores configured resolution for each ADC unit.

Array indexed by ADC unit number (0 or 1). Records the resolution configured during first `adc_init()` call for each unit. Subsequent init calls must use the same resolution (enforced at runtime).

Index	Unit	Default	Valid Values
0	S12AD0	12-bit	8, 10, 12
1	S12AD1	12-bit	8, 10, 12

Note

Resolution is set only on first init and cannot be changed

```
00001 /**
00002  * @file adc.c
00003  * @brief ADC Driver for RX72N S12ADFa - 12-bit Analog-to-Digital Conversion
00004  *
00005  * @details
00006  * ## Overview
00007  *
00008  * This file provides the hardware abstraction layer (HAL) for the S12ADFa
00009  * (12-bit Analog-to-Digital Converter) peripheral on the Renesas RX72N
00010  * microcontroller. The S12ADFa supports dual ADC units with 8 channels each,
00011  * configurable resolution (8/10/12-bit), and single-scan conversion mode.
00012  *
00013  * ## Hardware Architecture
00014  *
00015  * @dot
00016  * digraph adc_architecture {
00017  *   rankdir=LR;
00018  *   node [shape=box, style=rounded];
00019  *
00020  *   subgraph cluster_analog {
00021  *     label="Analog Inputs";
00022  *     style=dashed;
00023  *     an0 [label="AN0-AN7\n(S12AD0)"];
```

```

00024 *   an1 [label="AN16-AN23\n(S12AD1)"];
00025 * }
00026 *
00027 * subgraph cluster_adc {
00028 *   label="S12ADFa Peripheral";
00029 *   style=filled;
00030 *   fillcolor=lightblue;
00031 *   mux [label="Channel MUX"];
00032 *   sar [label="12-bit SAR\nConverter"];
00033 *   regs [label="ADDRn\nData Registers"];
00034 * }
00035 *
00036 * subgraph cluster_sw {
00037 *   label="Software (THIS FILE)";
00038 *   style=dashed;
00039 *   init [label="adc_init()"];
00040 *   read [label="adc_read()"];
00041 *   voltage [label="adc_read_voltage_mv()"];
00042 * }
00043 *
00044 * an0 -> mux;
00045 * an1 -> mux;
00046 * mux -> sar;
00047 * sar -> regs;
00048 * init -> regs [label="configure"];
00049 * read -> regs [label="trigger & read"];
00050 * voltage -> read [label="calls"];
00051 * }
00052 * @enddot
00053 *
00054 * ## S12ADFa Features Used
00055 *
00056 * | Feature | Status | Notes |
00057 * |-----|-----|-----|
00058 * | Dual ADC units (S12AD0, S12AD1) | [OK] | Both supported |
00059 * | 12/10/8-bit resolution | [OK] | Configurable per unit |
00060 * | Single-scan mode | [OK] | Software-triggered |
00061 * | Continuous scan mode | [X] | Not implemented |
00062 * | Group scan mode | [X] | Not implemented |
00063 * | A/D interrupts | [X] | Polling only |
00064 * | Self-diagnosis | [X] | Not implemented |
00065 * | Double trigger | [X] | Not implemented |
00066 *
00067 * ## Register Access Pattern
00068 *
00069 * @msc
00070 * Application, ADC_HAL, MSTPCRA, ADCSR, ADDRn;
00071 *
00072 * ... [label="Initialization"];
00073 * Application => ADC_HAL [label="adc_init(unit=0, ch=2, bits=12)"];
00074 * ADC_HAL => MSTPCRA [label="Clear bit 17 (enable S12AD0)"];
00075 * ADC_HAL => ADCSR [label="Configure resolution"];
00076 * ADC_HAL => Application [label="k_rx_ok"];
00077 *
00078 * ... [label="Conversion"];
00079 * Application => ADC_HAL [label="adc_read(unit=0, ch=2, &value)"];
00080 * ADC_HAL => ADCSR [label="Set ADST bit (start)"];
00081 * ADC_HAL box ADC_HAL [label="Poll ADST until clear"];
00082 * ADC_HAL => ADDRn [label="Read ADDR2"];
00083 * ADC_HAL => Application [label="k_rx_ok, value=raw"];
00084 * @endmsc
00085 *
00086 * ## Conversion Timing
00087 *
00088 * | Resolution | Conversion Time | Sample Rate (max) |
00089 * |-----|-----|-----|
00090 * | 12-bit | ~1.0 us | ~1 MHz |
00091 * | 10-bit | ~0.9 us | ~1.1 MHz |
00092 * | 8-bit | ~0.8 us | ~1.25 MHz |
00093 *
00094 * Note: Times are approximate at PCLKB = 60 MHz.
00095 *
00096 * ## Voltage Calculation
00097 *
00098 * The adc_read_voltage_mv() function converts raw ADC values to millivolts:
00099 *
00100 * @f[
00101 * 
$$V_{\text{mV}} = \frac{V_{\text{raw}}}{2^{\text{bits}} - 1} \times V_{\text{ref}}$$

00102 * @f]
00103 *
00104 * Where:
00105 * - @f$ V_{\text{raw}} @f$ = Raw ADC value (0 to 2bits-1)
00106 * - @f$ V_{\text{ref}} @f$ = Reference voltage (3300 mV)
00107 * - @f$ bits @f$ = Resolution (8, 10, or 12)
00108 *
00109 * ## Thread Safety
00110 *

```

```

00111 * | Function | Thread-Safe | Notes |
00112 * |-----|-----|-----|
00113 * | adc_init() | No | Call during initialization only |
00114 * | adc_read() | No | Caller must synchronize |
00115 * | adc_read_voltage_mv() | No | Caller must synchronize |
00116 *
00117 * Each ADC unit can be accessed independently, but concurrent access to the
00118 * same unit requires external synchronization.
00119 *
00120 * ## Memory Usage
00121 *
00122 * | Section | Size | Contents |
00123 * |-----|-----|-----|
00124 * | .text | ~800 bytes | Function code |
00125 * | .rodata | ~80 bytes | Log strings, tag |
00126 * | .bss | 6 bytes | s_adc_unit_initialized[2], s_adc_unit_resolution[2] |
00127 *
00128 * ## NASA Power of 10 Compliance
00129 *
00130 * | Rule | Status | Implementation |
00131 * |-----|-----|-----|
00132 * | 1. Simplify control flow | [OK] | No goto, setjmp, recursion |
00133 * | 2. Fixed loop bounds | [OK] | Timeout loop has fixed maximum |
00134 * | 3. No dynamic memory | [OK] | Static arrays only |
00135 * | 4. Functions < 60 lines | [OK] | Helper functions for decomposition |
00136 * | 5. Use assertions | [OK] | RX_CHECK_NULL_PTR, RX_CHECK_RANGE_TAG |
00137 * | 6. Data at smallest scope | [OK] | Local variables, static helpers |
00138 * | 7. Check return values | [OK] | RX_RETURN_ON_ERROR macro |
00139 * | 8. Limit preprocessor | [OK] | Only includes |
00140 * | 9. Restrict pointers | [OK] | Hardware register pointers only |
00141 * | 10. Compile warnings | [OK] | -Wall -Wextra -Werror clean |
00142 *

Enumerations

- enum [gpio_bit_constants_t](#) : uint8_t { [k_gpio_bit_set](#) = 1 , [k_gpio_bit_clear](#) = 0 }
GPIO register bit manipulation constants.

Functions

- static rx_err_t [internal_validate_port_pin](#) (const uint8_t port, const uint8_t pin)
Validate port and pin numbers against RX72N hardware limits.
- rx_err_t [gpio_set_output](#) (const rx_port_pin_t pin)
Configure GPIO pin as digital output.
- rx_err_t [gpio_set_input](#) (const rx_port_pin_t pin)
Configure GPIO pin as digital input.
- rx_err_t [gpio_write_high](#) (const rx_port_pin_t pin)
Set GPIO output pin to logic high (3.3V).
- rx_err_t [gpio_write_low](#) (const rx_port_pin_t pin)
Set GPIO output pin to logic low (0V).
- rx_err_t [gpio_toggle](#) (const rx_port_pin_t pin)
Toggle GPIO output pin state (high<->low).
- rx_err_t [gpio_read](#) (const rx_port_pin_t pin, bool *value)
Read GPIO input pin state.

Variables

- static const char *const [s_tag](#) = "GPIO"
Log tag for this module.

8.103.1 Detailed Description

GPIO Driver for RX72N - General Purpose Input/Output Control.

8.103.1.1 Overview

This file provides the hardware abstraction layer (HAL) for GPIO operations on the Renesas RX72N microcontroller. It handles pin direction configuration, digital output control, and digital input reading with integrated error handling, logging, and pin validation through the pin validator interface.

8.103.1.2 System Architecture

8.103.1.3 RX72N GPIO Register Architecture

Each GPIO port on the RX72N has multiple control registers:

Register	Name	Purpose
PDR	Port Direction Register	0=input, 1=output
PODR	Port Output Data Register	Output level (0=low, 1=high)
PIDR	Port Input Data Register	Read current pin level
PMR	Port Mode Register	0=GPIO, 1=peripheral function
PCR	Pull-up Control Register	Enable internal pull-up
ODR	Open-Drain Control Register	Enable open-drain mode

This driver primarily uses PDR, PODR, PIDR, and PMR.

8.103.1.4 Pin Configuration Sequence

8.103.1.5 Thread Safety

Function	Thread-Safe	Notes
gpio_set_output()	Partial	Pin reservation is mutex-protected
gpio_set_input()	Partial	Pin reservation is mutex-protected
gpio_write_high()	No	Direct register write
gpio_write_low()	No	Direct register write
gpio_toggle()	No	Read-modify-write, not atomic
gpio_read()	Yes	Read-only operation

For thread-safe output operations, caller must provide synchronization.

8.103.1.6 Performance Characteristics

Operation	Cycles	Time @ 240 MHz	Notes
<code>gpio_set_output</code>	~200-500	~1-2 us	Includes pin reservation
<code>gpio_set_input</code>	~200-500	~1-2 us	Includes pin reservation
<code>gpio_write_high</code>	~20-30	~100 ns	Direct register
<code>gpio_write_low</code>	~20-30	~100 ns	Direct register
<code>gpio_toggle</code>	~30-40	~150 ns	Read-modify-write
<code>gpio_read</code>	~20-30	~100 ns	Direct register read

8.103.1.7 Memory Usage

Section	Size	Contents
.text	~600 bytes	Function code
.rodata	~100 bytes	Log strings
.bss	0 bytes	No module-level state

8.103.1.8 NASA Power of 10 Compliance

Rule	Status	Implementation
1. Simplify control flow	↔ [OK]↔	No goto, setjmp, recursion
2. Fixed loop bounds	↔ [OK]↔	No loops in this module
3. No dynamic memory	↔ [OK]↔	All static, no malloc
4. Functions < 60 lines	↔ [OK]↔	All functions under 30 lines
5. Use assertions	↔ [OK]↔	RX_CHECK_NULL_PTR, validation
6. Data at smallest scope	↔ [OK]↔	Local variables only
7. Check return values	↔ [OK]↔	RX_RETURN_ON_ERROR macro
8. Limit preprocessor	↔ [OK]↔	Only includes
9. Restrict pointers	↔ [OK]↔	Only hardware register pointers
10. Compile warnings	↔ [OK]↔	-Wall -Wextra -Werror clean

8.103.1.9 SOLID Principles

Principle	Implementation
Single Responsibility	GPIO operations only (no PWM, no ADC)
Open/Closed	Extended via rx_port_pin_t encoding

Principle	Implementation
Liskov Substitution	N/A (not interface-based)
Interface Segregation	Separate functions for each operation
Dependency Inversion	Uses <code>pin_interface_t</code> for validation

8.103.2 Enumeration Type Documentation

8.103.2.1 `gpio_bit_constants_t`

enum [gpio_bit_constants_t](#) : `uint8_t`

GPIO register bit manipulation constants.

Defines constants used for bit manipulation in GPIO register operations. Using named constants instead of magic numbers improves code readability and makes the intent of bit operations clear.

8.103.2.2 Usage Examples

```
// Set bit 5 in PDR register (configure as output)
port->pdr |= (k_gpio_bit_set « 5);

// Clear bit 3 in PMR register (configure as GPIO, not peripheral)
port->pmr &= ~(k_gpio_bit_set « 3);

// Check if bit 2 is set in PIDR register
if ((port->pidr & (k_gpio_bit_set « 2)) != k_gpio_bit_clear) {
    // Pin is high
}
```

Enumerator

k_gpio_bit_set	Value for setting a single bit (1 << n pattern)
k_gpio_bit_clear	Value for comparison when checking if bit is cleared

Definition at line 201 of file [gpio.c](#).

```
00201      : uint8_t {
00202  k_gpio_bit_set    = 1, /**< Value for setting a single bit (1 « n pattern) */
00203  k_gpio_bit_clear  = 0, /**< Value for comparison when checking if bit is cleared */
00204 } gpio_bit_constants_t;
```

8.103.3 Function Documentation

8.103.3.1 gpio`read()

```
rx_err_t gpio_read (
    const rx_port_pin_t pin,
    bool * value)    [nodiscard]
```

Read GPIO input pin state.

Read current logic level of GPIO pin.

Reads the current logic level of a GPIO pin. Uses the PIDR (Port Input Data Register) which reflects the actual voltage level on the pin, regardless of whether the pin is configured as input or output.

8.103.3.2 Register Operation

```
value = (PIDR & (1 « pin)) != 0
```

8.103.3.3 Input vs Output Reading

- Input pin: PIDR reflects external voltage on pin
- Output pin: PIDR reflects actual pin state (may differ from PODR if pin is shorted or overdriven)

8.103.3.4 Voltage Thresholds (RX72N)

Level	Voltage Range	Returned Value
Low	0V to ~0.8V	false
High	~2.0V to VCC	true
Undefined	0.8V to 2.0V	Unpredictable

Precondition

value must be non-nullptr

Pin should be configured as input for external signals

Postcondition

*value contains current pin level (true=high, false=low)

No hardware state changes

Note

Thread-safe: Read-only operation

Performance: ~100 ns @ 240 MHz

ISR-safe: Can be called from interrupt handlers

Warning

Floating inputs may return unpredictable values

Use pull-up/pull-down for stable readings on open pins

Example:

```
// Read button state (active low with pull-up)
bool button_pressed;
rx_err_t err = gpio_read(RX_PORT_PIN(2, 0), &button_pressed);

if (err == k_rx_ok) {
    // Invert because button is active low
    if (!button_pressed) {
        rx_log_info("BTN", "Button pressed");
        handle_button_press();
    }
}
```

Example: Debounced button read

```
bool debounced_read(rx_port_pin_t pin) {
    bool first, second;
    gpio_read(pin, &first);
    tx_thread_sleep(1); // 1 tick delay
    gpio_read(pin, &second);
    return (first == second) ? first : false; // Only return if stable
}
```

```
00804 {
00805     /* Check null pointer */
00806     RX_CHECK_NULL_PTR(value, s_tag, "Value pointer is nullptr");
00807
00808     /* Extract port and pin number from rx_port_pin_t */
00809     const uint8_t port = rx_port_from_pin(pin);
00810     const uint8_t pin_num = rx_pin_from_pin(pin);
00811
00812     /* Validate parameters */
00813     const rx_err_t err = internal_validate_port_pin(port, pin_num);
00814     RX_RETURN_ON_ERROR(err, s_tag, "Port/pin validation failed");
00815
00816     /* Get port base address */
00817     const volatile rx_port_regs_t* port_base = rx_port_get_base(port);
00818
00819     const uint8_t pin_mask = (uint8_t)(k_gpio_bit_set « pin_num);
00820     *value = (port_base->pidr & pin_mask) != k_gpio_bit_clear;
00821
00822     return k_rx_ok;
00823 }
```

References [internal_validate_port_pin\(\)](#), [k_gpio_bit_clear](#), [k_gpio_bit_set](#), [rx_port_regs_t::pidr](#), [rx_port_get_base\(\)](#), and [s_tag](#).

Here is the call graph for this function:

8.103.3.5 gpio_set_input()

```
rx_err_t gpio_set_input (
    const rx_port_pin_t pin) [nodiscard]
```

Configure GPIO pin as digital input.

Configures a GPIO pin for digital input mode. This function performs:

1. Parameter validation (port and pin number)
2. Pin reservation via the global pin validator (conflict detection)
3. PMR register clear (select GPIO mode instead of peripheral function)
4. PDR register clear (configure as input direction)

8.103.3.6 Register Operations

```
PMR &= ~(1 « pin) // Clear bit: Select GPIO mode (not peripheral)
PDR &= ~(1 « pin) // Clear bit: Configure as input
```

8.103.3.7 Pull-up Configuration

This function does NOT configure internal pull-up resistors. To enable pull-ups, additional configuration of the PCR register is required.

8.103.3.8 Reading Input State

After configuration, use [gpio_read\(\)](#) to read the current pin state. The PIDR register is read for input state, not PODR.

Precondition

- Pin must be a valid GPIO-capable pin on RX72N
- System infrastructure should be initialized (for pin validation)

Postcondition

- Pin is configured as GPIO input
- PMR bit for pin is cleared (GPIO mode)
- PDR bit for pin is cleared (input direction)
- Pin is reserved in validator (if available)

Note

- Thread-safe: Pin reservation uses mutex
- Performance: ~1-2 us @ 240 MHz (includes reservation)
- Pull-ups: Not enabled by this function (use PCR register)

Warning

- Floating inputs may read unpredictable values - use pull-up/pull-down
- Do not call from ISR (pin reservation may block)

Example:

```
// Configure button pin as input
rx_err_t err = gpio_set_input(RX_PORT_PIN(2, 0)); // Port 2, Pin 0
if (err != k_rx_ok) {
    rx_log_error("BTN", "Failed to configure button pin");
    return err;
}

// Read button state
bool pressed;
err = gpio_read(RX_PORT_PIN(2, 0), &pressed);
if (err == k_rx_ok && pressed) {
    rx_log_info("BTN", "Button pressed");
}
```

00484     const uint8_t port = rx_port_from_pin(pin);
00485     const uint8_t pin_num = rx_pin_from_pin(pin);
00486
00487     /* Validate parameters */
00488     rx_err_t err = internal_validate_port_pin(port, pin_num);
00489     RX_RETURN_ON_ERROR(err, s_tag, "Port/pin validation failed");
00490
00491     /* Reserve pin through global pin validator */
00492     const rx_pin_interface_t* const pin_iface = rx_infrastructure_get_pin_interface();
00493     if (pin_iface != nullptr) {
00494         err = pin_iface->reserve_pin(pin_iface->ctx, port, pin_num, "GPIO_IN");
00495         if (err != k_rx_ok && err != k_rx_err_gpio_conflict) {
00496             /* Allow conflict (pin already reserved), but fail on other errors */
00497             RX_RETURN_ON_ERROR(err, s_tag, "Pin reservation failed");
00498         }
00499     }
00500
00501     /* Get port base address */
00502     volatile rx_port_regs_t* port_base = rx_port_get_base(port);
00503
00504     /* Set as GPIO mode */
00505     const uint8_t pin_mask = (uint8_t)(k_gpio_bit_set « pin_num);
00506     port_base->pmr &= (uint8_t)~pin_mask;
00507
00508     /* Set as input */
00509     port_base->pdr &= (uint8_t)~pin_mask;
00510
00511     rx_log_debug(s_tag, "Pin configured as input");
00512
00513     return k_rx_ok;
00514 }
```

References [internal_validate_port_pin\(\)](#), [k_gpio_bit_set](#), [rx_port_regs_t::pdr](#), [rx_port_regs_t::pmr](#), [rx_port_get_base\(\)](#), and [s_tag](#).

Here is the call graph for this function:

8.103.3.9 gpio`set`output()

```
rx_err_t gpio_set_output (
    const rx_port_pin_t pin) [nodiscard]
```

Configure GPIO pin as digital output.

Configures a GPIO pin for digital output mode. This function performs:

1. Parameter validation (port and pin number)
2. Pin reservation via the global pin validator (conflict detection)
3. PMR register clear (select GPIO mode instead of peripheral function)
4. PDR register set (configure as output direction)

8.103.3.10 Register Operations

```
PMR &= ~(1 « pin) // Clear bit: Select GPIO mode (not peripheral)
PDR |= (1 « pin) // Set bit: Configure as output
```

8.103.3.11 Pin Reservation

The function attempts to reserve the pin through `rx_infrastructure_get_pin_interface()`. If the pin is already reserved (`k_rx_err_gpio_conflict`), the function continues without error - this allows reconfiguration of already-owned pins.

8.103.3.12 Initial Output State

This function does NOT set the initial output level. After calling `gpio_set_output()`, call `gpio_write_high()` or `gpio_write_low()` to set the desired level.

Precondition

- Pin must be a valid GPIO-capable pin on RX72N
- System infrastructure should be initialized (for pin validation)

Postcondition

- Pin is configured as GPIO output
- PMR bit for pin is cleared (GPIO mode)
- PDR bit for pin is set (output direction)
- Pin is reserved in validator (if available)

Note

- Thread-safe: Pin reservation uses mutex, register writes are not atomic
- Performance: ~1-2 us @ 240 MHz (includes reservation)
- Idempotent: Safe to call multiple times on same pin

Warning

- Output level is undefined after this call - set with `gpio_write_*`
- Do not call from ISR (pin reservation may block)

Example:

```
// Configure LED pin as output
rx_err_t err = gpio_set_output(RX_PORT_PIN(0, 3)); // Port 0, Pin 3
if (err != k_rx_ok) {
    rx_log_error("LED", "Failed to configure LED pin");
    return err;
}

// Set initial state to low (LED off)
gpio_write_low(RX_PORT_PIN(0, 3));

// Toggle LED
gpio_toggle(RX_PORT_PIN(0, 3));
```

00405
00406  rx_log_debug(s_tag, "Pin configured as output");
00407
00408  return k_rx_ok;
00409 }
```

References [internal_validate_port_pin\(\)](#), [k_gpio_bit_set](#), [rx_port_regs_t::pdr](#), [rx_port_regs_t::pmr](#), [rx_port_get_base\(\)](#), and [s_tag](#).

Here is the call graph for this function:

8.103.3.13 gpio_toggle()

```
rx_err_t gpio_toggle (
    const rx_port_pin_t pin) [nodiscard]
```

Toggle GPIO output pin state (high<->low).

Toggle GPIO output pin state (high to low, or low to high).

Inverts the current output state of a GPIO pin. If the pin is currently high, it becomes low. If currently low, it becomes high. Uses XOR operation for efficient toggling.

8.103.3.14 Register Operation

```
PODR ^= (1 « pin) // XOR bit: Toggle output
```

8.103.3.15 Atomicity Warning

This operation is a read-modify-write sequence and is NOT atomic. If an interrupt modifies the same port register between the read and write, the interrupt's change may be lost.

For thread-safe toggling, use explicit `write_high/write_low` with external synchronization, or disable interrupts around the toggle.

Precondition

Pin must be configured as output via [gpio_set_output\(\)](#)

Port and pin numbers must be valid

Postcondition

PODR bit for pin is inverted

Pin output level is opposite of previous state

Note

NOT thread-safe: Read-modify-write operation

NOT atomic: Can race with ISRs on same port

Performance: ~150 ns @ 240 MHz

Warning

Race condition possible with ISRs modifying same port

Use `gpio_write_high/low` with sync for critical applications

Example:

```
// Blink LED in loop
while (running) {
    gpio_toggle(RX_PORT_PIN(0, 3)); // Toggle LED
    tx_thread_sleep(50);             // 50ms delay (20 Hz blink)
}
```

00707 {
00708     /* Extract port and pin number from rx_port_pin_t */
00709     const uint8_t port = rx_port_from_pin(pin);
00710     const uint8_t pin_num = rx_pin_from_pin(pin);
00711
00712     /* Validate parameters */
00713     const rx_err_t err = internal_validate_port_pin(port, pin_num);
00714     RX_RETURN_ON_ERROR(err, s_tag, "Port/pin validation failed");
00715
00716     /* Get port base address */
00717     volatile rx_port_regs_t* port_base = rx_port_get_base(port);
00718
00719     const uint8_t pin_mask = (uint8_t)(k_gpio_bit_set « pin_num);
00720     port_base->podr ^= pin_mask;
00721
00722     return k_rx_ok;
00723 }
```

References [internal_validate_port_pin\(\)](#), [k_gpio_bit_set](#), [rx_port_regs_t::podr](#), [rx_port_get_base\(\)](#), and [s_tag](#).

Here is the call graph for this function:

8.103.3.16 gpio`write`high()

```
rx_err_t gpio_write_high (
    const rx_port_pin_t pin) [nodiscard]
```

Set GPIO output pin to logic high (3.3V).

Set GPIO output pin to logic high (VDD).

Sets a GPIO output pin to logic high level. On the RX72N, this means the pin outputs VCC (typically 3.3V). The pin must be configured as an output before calling this function.

8.103.3.17 Register Operation

```
PODR |= (1 « pin) // Set bit: Output high
```

8.103.3.18 Timing

The output level changes on the next peripheral clock cycle after the register write completes. GPIO toggle rate is limited by bus speed.

Precondition

- Pin must be configured as output via [gpio_set_output\(\)](#)
- Port and pin numbers must be valid

Postcondition

- PODR bit for pin is set (output high)
- Pin outputs VCC level (typically 3.3V)

Note

- NOT thread-safe: Direct register write without synchronization
- Performance: ~100 ns @ 240 MHz
- ISR-safe: Can be called from interrupt handlers

Warning

- No check that pin is configured as output
- Calling on input pin has no visible effect

Example:

```
// Turn on LED (active high)
rx_err_t err = gpio_write_high(RX_PORT_PIN(0, 3));
if (err != k_rx_ok) {
    // Handle error
}
```

00566 {
00567     /* Extract port and pin number from rx_port_pin_t */
00568     const uint8_t port    = rx_port_from_pin(pin);
00569     const uint8_t pin_num = rx_pin_from_pin(pin);
00570
00571     /* Validate parameters */
00572     const rx_err_t err = internal_validate_port_pin(port, pin_num);
00573     RX_RETURN_ON_ERROR(err, s_tag, "Port/pin validation failed");
00574
00575     /* Get port base address */
00576     volatile rx_port_regs_t* port_base = rx_port_get_base(port);
00577
00578     const uint8_t pin_mask = (uint8_t)(k_gpio_bit_set « pin_num);
00579     port_base->podr |= pin_mask;
00580
00581     return k_rx_ok;
00582 }
```

References [internal_validate_port_pin\(\)](#), [k_gpio_bit_set](#), [rx_port_regs_t::podr](#), [rx_port_get_base\(\)](#), and [s_tag](#).

Here is the call graph for this function:

8.103.3.19 gpio_write_low()

```
rx_err_t gpio_write_low (
    const rx_port_pin_t pin) [nodiscard]
```

Set GPIO output pin to logic low (0V).

Set GPIO output pin to logic low (GND).

Sets a GPIO output pin to logic low level. On the RX72N, this means the pin outputs GND (0V). The pin must be configured as an output before calling this function.

8.103.3.20 Register Operation

```
PODR &= ~(1 « pin) // Clear bit: Output low
```

8.103.3.21 Open-Drain Mode

If the pin is configured for open-drain mode (ODR register), setting low actively pulls the pin to GND. Setting high makes the pin float (high-impedance), requiring an external pull-up.

Precondition

- Pin must be configured as output via [gpio_set_output\(\)](#)
- Port and pin numbers must be valid

Postcondition

- PODR bit for pin is cleared (output low)
- Pin outputs GND level (0V)

Note

- NOT thread-safe: Direct register write without synchronization
- Performance: ~100 ns @ 240 MHz
- ISR-safe: Can be called from interrupt handlers

Warning

- No check that pin is configured as output
- Calling on input pin has no visible effect

Example:

```
// Turn off LED (active high)
rx_err_t err = gpio_write_low(RX_PORT_PIN(0, 3));
if (err != k_rx_ok) {
    // Handle error
}
```

00647     const uint8_t pin_mask = (uint8_t)(k_gpio_bit_set « pin_num);
00648     port_base->podr &= (uint8_t)~pin_mask;
00649
00650     return k_rx_ok;
00651 }
```

References [internal_validate_port_pin\(\)](#), [k_gpio_bit_set](#), [rx_port_regs_t::podr](#), [rx_port_get_base\(\)](#), and [s_tag](#).

Here is the call graph for this function:

8.103.3.22 internal_validate_port_pin()

```

rx_err_t internal_validate_port_pin (
    const uint8_t port,
    const uint8_t pin) [static]
  
```

Validate port and pin numbers against RX72N hardware limits.

Performs validation of GPIO port and pin numbers before any register access. This function is called by all public GPIO functions to ensure safe operation and prevent out-of-bounds hardware register access.

8.103.3.23 Validation Algorithm

1. Check port validity via [rx_port_get_base\(\)](#) (returns NULL for invalid ports)
2. Check pin number against k_rx_pin_max (maximum valid pin number per port)

8.103.3.24 Port Validation

Uses `rx_port_get_base()` which returns NULL for any port number that does not correspond to a physical port on the RX72N. Valid port numbers are 0-9 (decimal) and 0xA-0x10 (hexadecimal, corresponding to ports A through G). Passing an out-of-range port is safely caught here before any register dereference occurs.

8.103.3.25 Pin Validation

Each RX72N GPIO port exposes up to 8 pins numbered 0 through 7. The `k_rx_pin_max` constant defines the inclusive upper bound (7). A lower-bound check against zero is omitted because `pin` is a `uint8_t`, making `pin < 0` structurally impossible; omitting it avoids a -Wtype-limits compiler warning.

8.103.3.26 Why Both Checks Are Required

An invalid port with a valid pin, or a valid port with an invalid pin, must both be rejected. Either condition alone would result in incorrect hardware register access, undefined behavior, or corrupted peripheral state.

Precondition

`port` must be within the RX72N valid port range (0-9, 0xA-0x10); values outside this range are rejected before any register access

`pin` must be within the valid pin range for the specified port (0 to `k_rx_pin_max`); values above `k_rx_pin_max` are rejected with an error

Postcondition

Returns `k_rx_ok` only when both port and pin are simultaneously valid; no partial-success return is possible

No hardware state is modified; this function is purely read-only with respect to peripheral registers and module-level variables

Note

Thread-safe: No shared mutable state accessed; safe to call concurrently

Performance: O(1), approximately 50 cycles at 240 MHz

An error log message is emitted for each failed validation to aid debugging

Example:

```
// Typical usage inside a GPIO public function
const uint8_t port = rx_port_from_pin(pin);
const uint8_t pin_num = rx_pin_from_pin(pin);
rx_err_t err = internal_validate_port_pin(port, pin_num);
RX_RETURN_ON_ERROR(err, s_tag, "Port/pin validation failed");
```

00001 /**
00002  * @file gpio.c
00003  * @brief GPIO Driver for RX72N - General Purpose Input/Output Control
00004  *
00005  * @details
00006  * ## Overview
00007  *
00008  * This file provides the hardware abstraction layer (HAL) for GPIO operations on
00009  * the Renesas RX72N microcontroller. It handles pin direction configuration,
00010  * digital output control, and digital input reading with integrated error handling,
00011  * logging, and pin validation through the pin validator interface.
00012  *
00013  * ## System Architecture
00014  *
00015  * @dot
00016  * digraph gpio_architecture {
00017  *   rankdir=TB;
00018  *   node [shape=box, style=rounded];
00019  *
00020  *   subgraph cluster_app {
00021  *     label="Application Layer";
00022  *     style=dashed;
00023  *     led [label="LED Control"];
00024  *     button [label="Button Input"];

00056 *
00057 * ## RX72N GPIO Register Architecture
00058 *
00059 * Each GPIO port on the RX72N has multiple control registers:
00060 *
00061 * | Register | Name | Purpose |
00062 * |-----|-----|-----|
00063 * | PDR | Port Direction Register | 0=input, 1=output |
00064 * | PODR | Port Output Data Register | Output level (0=low, 1=high) |
00065 * | PIDR | Port Input Data Register | Read current pin level |
00066 * | PMR | Port Mode Register | 0=GPIO, 1=peripheral function |
00067 * | PCR | Pull-up Control Register | Enable internal pull-up |
00068 * | ODR | Open-Drain Control Register | Enable open-drain mode |
00069 *
00070 * This driver primarily uses PDR, PODR, PIDR, and PMR.
00071 *
00072 * ## Pin Configuration Sequence
00073 *
00074 * @msc
00075 * App, GPIO, PinValidator, PortRegs;
00076 *
00077 * App => GPIO [label="gpio_set_output(pin)"];
00078 * GPIO => PinValidator [label="reserve_pin(port, pin, 'GPIO_OUT')"];
00079 * PinValidator => GPIO [label="k_rx_ok"];
00080 * GPIO => PortRegs [label="PMR &= ~(1«pin) // GPIO mode"];
00081 * GPIO => PortRegs [label="PDR |= (1«pin) // Output"];
00082 * GPIO => App [label="k_rx_ok"];
00083 *
00084 * App => GPIO [label="gpio_write_high(pin)"];
00085 * GPIO => PortRegs [label="PODR |= (1«pin)"];
00086 * GPIO => App [label="k_rx_ok"];
00087 * @endmsc
00088 *
00089 * ## Thread Safety
00090 *
00091 * | Function | Thread-Safe | Notes |
00092 * |-----|-----|-----|
00093 * | gpio_set_output() | Partial | Pin reservation is mutex-protected |
00094 * | gpio_set_input() | Partial | Pin reservation is mutex-protected |
00095 * | gpio_write_high() | No | Direct register write |
00096 * | gpio_write_low() | No | Direct register write |
00097 * | gpio_toggle() | No | Read-modify-write, not atomic |
00098 * | gpio_read() | Yes | Read-only operation |
00099 *
00100 * For thread-safe output operations, caller must provide synchronization.
00101 *
00102 * ## Performance Characteristics
00103 *
00104 * | Operation | Cycles | Time @ 240 MHz | Notes |
00105 * |-----|-----|-----|-----|
00106 * | gpio_set_output | ~200-500 | ~1-2 us | Includes pin reservation |
00107 * | gpio_set_input | ~200-500 | ~1-2 us | Includes pin reservation |
00108 * | gpio_write_high | ~20-30 | ~100 ns | Direct register |
00109 * | gpio_write_low | ~20-30 | ~100 ns | Direct register |
00110 * | gpio_toggle | ~30-40 | ~150 ns | Read-modify-write |
00111 * | gpio_read | ~20-30 | ~100 ns | Direct register read |
00112 *
00113 * ## Memory Usage

```

```

00114 *
00115 * | Section | Size | Contents |
00116 * |-----|-----|-----|
00117 * | .text | ~600 bytes | Function code |
00118 * | .rodata | ~100 bytes | Log strings |
00119 * | .bss | 0 bytes | No module-level state |
00120 *
00121 * ## NASA Power of 10 Compliance
00122 *
00123 * | Rule | Status | Implementation |
00124 * |-----|-----|-----|
00125 * | 1. Simplify control flow | [OK] | No goto, setjmp, recursion |
00126 * | 2. Fixed loop bounds | [OK] | No loops in this module |
00127 * | 3. No dynamic memory | [OK] | All static, no malloc |
00128 * | 4. Functions < 60 lines | [OK] | All functions under 30 lines |
00129 * | 5. Use assertions | [OK] | RX_CHECK_NULL_PTR, validation |
00130 * | 6. Data at smallest scope | [OK] | Local variables only |
00131 * | 7. Check return values | [OK] | RX_RETURN_ON_ERROR macro |
00132 * | 8. Limit preprocessor | [OK] | Only includes |
00133 * | 9. Restrict pointers | [OK] | Only hardware register pointers |
00134 * | 10. Compile warnings | [OK] | -Wall -Wextra -Werror clean |
00135 *
00136 * ## SOLID Principles
00137 *
00138 * | Principle | Implementation |
00139 * |-----|-----|
00140 * | **Single Responsibility** | GPIO operations only (no PWM, no ADC) |
00141 * | **Open/Closed** | Extended via rx_port_pin_t encoding |
00142 * | **Liskov Substitution** | N/A (not interface-based) |
00143 * | **Interface Segregation** | Separate functions for each operation |
00144 * | **Dependency Inversion** | Uses pin_interface_t for validation |
00145 *
00146 * @see rx_port_constants.h Port and pin definitions
00147 * @see rx_port_utils.h Port address lookup utilities
00148 * @see rx72n_regs.h Register definitions
00149 * @see rx_pin_validator.h Pin conflict detection
00150 *

00173 * @enum gpio_bit_constants_t
00174 * @brief GPIO register bit manipulation constants
00175 *
00176 * @details
00177 * Defines constants used for bit manipulation in GPIO register operations.
00178 * Using named constants instead of magic numbers improves code readability
00179 * and makes the intent of bit operations clear.
00180 *
00181 * ## Usage Examples
00182 *
00183 * @code
00184 * // Set bit 5 in PDR register (configure as output)
00185 * port->pdr |= (k_gpio_bit_set « 5);
00186 *
00187 * // Clear bit 3 in PMR register (configure as GPIO, not peripheral)
00188 * port->pmr &= ~(k_gpio_bit_set « 3);
00189 *
00190 * // Check if bit 2 is set in PIDR register
00191 * if ((port->pidr & (k_gpio_bit_set « 2)) != k_gpio_bit_clear) {
00192 * // Pin is high
00193 * }
00194 * @endcode
00195 *
00196 * @see gpio_set_output() Uses these for PDR/PMR manipulation
00197 * @see gpio_read() Uses these for PIDR comparison
00198 *

```

```

00199 * @since Version 1.0.0
00200 */
00201 typedef enum : uint8_t {
00202     k_gpio_bit_set    = 1, /**< Value for setting a single bit (1 « n pattern) */
00203     k_gpio_bit_clear = 0, /**< Value for comparison when checking if bit is cleared */
00204 } gpio_bit_constants_t;

=====
00212 */
00213
00214 /**
00215  * @brief Validate port and pin numbers against RX72N hardware limits
00216  *
00217  * @details
00218  * Performs validation of GPIO port and pin numbers before any register access.
00219  * This function is called by all public GPIO functions to ensure safe operation
00220  * and prevent out-of-bounds hardware register access.
00221  *
00222  * ## Validation Algorithm
00223  *
00224  * 1. Check port validity via rx_port_get_base() (returns NULL for invalid ports)
00225  * 2. Check pin number against k_rx_pin_max (maximum valid pin number per port)
00226  *
00227  * ## Port Validation
00228  *
00229  * Uses rx_port_get_base() which returns NULL for any port number that does not
00230  * correspond to a physical port on the RX72N. Valid port numbers are 0-9
00231  * (decimal) and 0xA-0x10 (hexadecimal, corresponding to ports A through G).
00232  * Passing an out-of-range port is safely caught here before any register
00233  * dereference occurs.
00234  *
00235  * ## Pin Validation
00236  *
00237  * Each RX72N GPIO port exposes up to 8 pins numbered 0 through 7. The
00238  * k_rx_pin_max constant defines the inclusive upper bound (7). A lower-bound
00239  * check against zero is omitted because pin is a uint8_t, making pin < 0
00240  * structurally impossible; omitting it avoids a -Wtype-limits compiler warning.
00241  *
00242  * ## Why Both Checks Are Required
00243  *
00244  * An invalid port with a valid pin, or a valid port with an invalid pin, must
00245  * both be rejected. Either condition alone would result in incorrect hardware
00246  * register access, undefined behavior, or corrupted peripheral state.
00247  *
00248  *
00249  *
00250  * @pre port must be within the RX72N valid port range (0-9, 0xA-0x10);
00251  *       values outside this range are rejected before any register access
00252  * @pre pin must be within the valid pin range for the specified port (0 to
00253  *       k_rx_pin_max); values above k_rx_pin_max are rejected with an error
00254  * @post Returns k_rx_ok only when both port and pin are simultaneously valid;
00255  *       no partial-success return is possible
00256  * @post No hardware state is modified; this function is purely read-only with
00257  *       respect to peripheral registers and module-level variables
00258  *
00259  * @note Thread-safe: No shared mutable state accessed; safe to call concurrently
00260  * @note Performance: O(1), approximately 50 cycles at 240 MHz
00261  * @note An error log message is emitted for each failed validation to aid debugging
00262  *
00263  * @par Example:
00264  * @code
00265  * // Typical usage inside a GPIO public function
00266  * const uint8_t port  = rx_port_from_pin(pin);
00267  * const uint8_t pin_num = rx_pin_from_pin(pin);
00268  * rx_err_t err = internal_validate_port_pin(port, pin_num);
00269  * RX_RETURN_ON_ERROR(err, s_tag, "Port/pin validation failed");
00270  * @endcode
00271  *
00272  * @see rx_port_get_base() Port lookup function used internally for port validation
00273  * @see k_rx_pin_max Maximum valid pin index (inclusive upper bound)
00274  *
00275  * @since Version 1.0.0
00276  *
00277  * @par NASA Power of 10 Compliance:
00278  * - Rule 5: [OK] 2 preconditions, 2 postconditions
00279  */

00300 * Public API Implementation
00301 *
=====
00302 */
00303
00304 /**
00305 * @brief Configure GPIO pin as digital output
00306 *
00307 * @details
00308 * Configures a GPIO pin for digital output mode. This function performs:
00309 * 1. Parameter validation (port and pin number)
00310 * 2. Pin reservation via the global pin validator (conflict detection)
00311 * 3. PMR register clear (select GPIO mode instead of peripheral function)
00312 * 4. PDR register set (configure as output direction)
00313 *
00314 * ## Register Operations
00315 *
00316 * ```
00317 * PMR &= ~(1 « pin) // Clear bit: Select GPIO mode (not peripheral)
00318 * PDR |= (1 « pin) // Set bit: Configure as output
00319 * ```
00320 *
00321 * ## Pin Reservation
00322 *
00323 * The function attempts to reserve the pin through rx_infrastructure_get_pin_interface().
00324 * If the pin is already reserved (k_rx_err_gpio_conflict), the function continues
00325 * without error - this allows reconfiguration of already-owned pins.
00326 *
00327 * ## Initial Output State
00328 *
00329 * This function does NOT set the initial output level. After calling gpio_set_output(),
00330 * call gpio_write_high() or gpio_write_low() to set the desired level.
00331 *
00332 *
00333 *
00334 * @pre Pin must be a valid GPIO-capable pin on RX72N
00335 * @pre System infrastructure should be initialized (for pin validation)
00336 *
00337 * @post Pin is configured as GPIO output
00338 * @post PMR bit for pin is cleared (GPIO mode)
00339 * @post PDR bit for pin is set (output direction)
00340 * @post Pin is reserved in validator (if available)
00341 *
00342 * @note Thread-safe: Pin reservation uses mutex, register writes are not atomic
00343 * @note Performance: ~1-2 us @ 240 MHz (includes reservation)
00344 * @note Idempotent: Safe to call multiple times on same pin
00345 *
00346 * @warning Output level is undefined after this call - set with gpio_write_*
00347 * @warning Do not call from ISR (pin reservation may block)
00348 *
00349 * @par Example:
00350 * @code
00351 * // Configure LED pin as output
00352 * rx_err_t err = gpio_set_output(RX_PORT_PIN(0, 3)); // Port 0, Pin 3
00353 * if (err != k_rx_ok) {
00354 *     rx_log_error("LED", "Failed to configure LED pin");
00355 *     return err;
00356 * }
00357 *
00358 * // Set initial state to low (LED off)
00359 * gpio_write_low(RX_PORT_PIN(0, 3));
00360 *
00361 * // Toggle LED
00362 * gpio_toggle(RX_PORT_PIN(0, 3));
00363 * @endcode
00364 *
00365 * @see gpio_set_input() Configure pin as input
00366 * @see gpio_write_high() Set output high after configuration
00367 * @see gpio_write_low() Set output low after configuration
00368 * @see RX_PORT_PIN() Macro to create rx_port_pin_t

00411 /**
00412 * @brief Configure GPIO pin as digital input
00413 *
00414 * @details
00415 * Configures a GPIO pin for digital input mode. This function performs:
00416 * 1. Parameter validation (port and pin number)
00417 * 2. Pin reservation via the global pin validator (conflict detection)
00418 * 3. PMR register clear (select GPIO mode instead of peripheral function)
00419 * 4. PDR register clear (configure as input direction)
00420 *
00421 * ## Register Operations
00422 *
00423 * ```
00424 * PMR &= ~(1 << pin) // Clear bit: Select GPIO mode (not peripheral)
00425 * PDR &= ~(1 << pin) // Clear bit: Configure as input
00426 * ```
00427 *
00428 * ## Pull-up Configuration
00429 *
00430 * This function does NOT configure internal pull-up resistors. To enable
00431 * pull-ups, additional configuration of the PCR register is required.
00432 *
00433 * ## Reading Input State
00434 *
00435 * After configuration, use gpio_read() to read the current pin state.
00436 * The PIDR register is read for input state, not PODR.
00437 *
00438 *
00439 *
00440 * @pre Pin must be a valid GPIO-capable pin on RX72N
00441 * @pre System infrastructure should be initialized (for pin validation)
00442 *
00443 * @post Pin is configured as GPIO input
00444 * @post PMR bit for pin is cleared (GPIO mode)
00445 * @post PDR bit for pin is cleared (input direction)
00446 * @post Pin is reserved in validator (if available)
00447 *
00448 * @note Thread-safe: Pin reservation uses mutex
00449 * @note Performance: ~1-2 us @ 240 MHz (includes reservation)
00450 * @note Pull-ups: Not enabled by this function (use PCR register)
00451 *
00452 * @warning Floating inputs may read unpredictable values - use pull-up/pull-down
00453 * @warning Do not call from ISR (pin reservation may block)
00454 *
00455 * @par Example:

```

```

00456 * @code
00457 * // Configure button pin as input
00458 * rx_err_t err = gpio_set_input(RX_PORT_PIN(2, 0)); // Port 2, Pin 0
00459 * if (err != k_rx_ok) {
00460 *     rx_log_error("BTN", "Failed to configure button pin");
00461 *     return err;
00462 * }
00463 *
00464 * // Read button state
00465 * bool pressed;
00466 * err = gpio_read(RX_PORT_PIN(2, 0), &pressed);
00467 * if (err == k_rx_ok && pressed) {
00468 *     rx_log_info("BTN", "Button pressed");
00469 * }
00470 * @endcode
00471 *
00472 * @see gpio_set_output() Configure pin as output
00473 * @see gpio_read() Read input pin state
00474 * @see RX_PORT_PIN() Macro to create rx_port_pin_t
00475 *
00476 * @since Version 1.0.0
00477 *

00725 /**
00726  * @brief Read GPIO input pin state
00727  *
00728  * @details
00729  * Reads the current logic level of a GPIO pin. Uses the PIDR (Port Input Data
00730  * Register) which reflects the actual voltage level on the pin, regardless
00731  * of whether the pin is configured as input or output.
00732  *
00733  * ## Register Operation
00734  *
00735  * ```
00736  * value = (PIDR & (1 « pin)) != 0
00737  * ```
00738  *
00739  * ## Input vs Output Reading
00740  *
00741  * - **Input pin**: PIDR reflects external voltage on pin
00742  * - **Output pin**: PIDR reflects actual pin state (may differ from PODR
00743  *   if pin is shorted or overdriven)
00744  *
00745  * ## Voltage Thresholds (RX72N)
00746  *
00747  * | Level | Voltage Range | Returned Value |
00748  * |-----|-----|-----|
00749  * | Low | 0V to ~0.8V | false |
00750  * | High | ~2.0V to VCC | true |
00751  * | Undefined | 0.8V to 2.0V | Unpredictable |
00752  *
00753  *
00754  *
00755  * @pre value must be non-nullptr
00756  * @pre Pin should be configured as input for external signals
00757  *
00758  * @post *value contains current pin level (true=high, false=low)
00759  * @post No hardware state changes
00760  *

8.105 libs/rx`hal/src/riic.c File Reference

RIIC (I2C) Driver Implementation for RX72N.

```

#include <string.h>
#include "hardware.h"
#include "rx72n_regs.h"
#include "rx_register_protection.h"

```

Include dependency graph for riic.c:

Data Structures

- struct [riic_recovery_pins_t](#)
Channel-specific port + pin info for bit-bang bus recovery.
- struct [riic_saved_cfg_t](#)
Wait for I2C bus to become idle (not busy).

Enumerations

- enum [riic_constants_t](#) : uint32_t {
[k_riic_max_channels](#) = 3 , [k_riic_timeout_us](#) = 25000 , [k_riic_timeout_zero](#) = 0 ,
[k_riic_length_zero](#) = 0 ,
[k_riic_register_clear](#) = 0 , [k_riic_last_index_offset](#) = 1 , [k_riic_max_transfer_length](#) = 256 }
RIIC channel count, timeout, and transfer limit constants.
- enum [riic_channel_num_t](#) : uint8_t { [k_riic_channel_0](#) = 0 , [k_riic_channel_1](#) = 1 ,
[k_riic_channel_2](#) = 2 }
RIIC channel identifiers for switch statement dispatch.
- enum [riic_module_stop_bits_t](#) : uint8_t { [k_riic_mstpb_riic0](#) = 21 , [k_riic_mstpb_riic1](#) = 20 ,
[k_riic_mstpc_riic2](#) = 17 , [k_riic_mstpb_bit_value](#) = 1 }
RIIC module stop bit positions in MSTPCRB (RIIC0/1) and MSTPCRC (RIIC2).
- enum [riic_frequency_t](#) : uint32_t { [k_riic_freq_100khz](#) = 100000 , [k_riic_freq_400khz](#) = 400000 ,
[k_riic_freq_1mhz](#) = 1000000 }
Supported I2C bus frequencies (Hz).

- enum `riic_bit_rate_t` : `uint8_t` {

Register bit-field constants for peripheral mode configuration.
- enum `riic_peripheral_size_constants_t` : `uint16_t` { `k_riic_periph_timeout_us` = 1000 }
Size and timeout constants for peripheral mode operations.

Functions

- static `uint8_t` `internal_riic_channel_from_base` (const volatile `rx_riic_regs_t` *riic)
Resolve a RIIC register pointer to its channel number.
- static void `internal_riic_busy_wait_us` (uint16_t us, uint16_t cpu_mhz)
Cycle-counted busy-wait for bit-bang timing.
- static void `internal_riic_bit_bang_recover` (uint8_t channel)
Bit-bang 9 SCL edges + manual STOP to recover an externally-stuck bus.
- static void `internal_riic_force_fsm_reset` (volatile `rx_riic_regs_t` *riic)
Raise PMR so the RIIC peripheral takes the pads back.
- static void `internal_riic_bit_bang_handback` (uint8_t channel)
- static volatile `rx_riic_regs_t` * `internal_get_riic_base` (const uint8_t channel)
Get RIIC channel register base address from channel number.
- static `rx_err_t` `internal_calculate_bit_rate` (const uint32_t frequency_hz, uint8_t *icbtl, uint8_t *icbrh, uint8_t *cks_field)
Calculate RIIC bit rate register values for target frequency.
- static bool `internal_riic_poll_bbsy_clear` (volatile `rx_riic_regs_t` *const riic)

- Poll BBSY for up to `k_riic_timeout_us` iterations.

 - static void `internal_riic_save_config` (const volatile `rx_riic_regs_t` *const riic, `riic_saved_cfg_t` *const saved)

Save config registers wiped by an IICRST pulse.

 - static void `internal_riic_iicrst_with_restore` (volatile `rx_riic_regs_t` *const riic, const `riic_saved_cfg_t` *const saved)

Pulse IICRST and restore config from a saved snapshot.

 - static void `internal_riic_release_lines` (volatile `rx_riic_regs_t` *const riic)

Drive the SOWP/SCLO/SDAO release dance after an IICRST pulse.

 - static void `internal_riic_log_pre_recovery` (const volatile `rx_riic_regs_t` *const riic)

Log debug-level pre-recovery bus state.

 - static void `internal_riic_bit_bang_recovery_sequence` (volatile `rx_riic_regs_t` *const riic, const `riic_saved_cfg_t` *const saved)

Bit-bang last-resort bus recovery + peripheral reset + handback.

 - static `rx_err_t` `internal_wait_bus_ready` (volatile `rx_riic_regs_t` *riic)
 - static `rx_err_t` `internal_send_start` (volatile `rx_riic_regs_t` *riic)

Generate I2C START condition on the bus.

 - static `rx_err_t` `internal_send_stop` (volatile `rx_riic_regs_t` *riic)

Generate I2C STOP condition on the bus.

 - static `rx_err_t` `internal_write_byte` (volatile `rx_riic_regs_t` *riic, const `uint8_t` data)

Transmit single byte over I2C bus.

 - static `rx_err_t` `internal_write_address_for_read` (volatile `rx_riic_regs_t` *riic, const `uint8_t` addr, const `uint8_t` addr_byte)

Send the address|R byte that opens a controller-receive transaction.

 - static `rx_err_t` `internal_read_byte` (volatile `rx_riic_regs_t` *riic, `uint8_t` *data, const bool send_ack, const bool last_byte)

Receive single byte from I2C bus.

 - static `rx_err_t` `internal_riic_write_phase` (volatile `rx_riic_regs_t` *riic, const `i2c_device_addr_t` device_addr, const `uint8_t` *write_data, const `uint16_t` write_length)

Execute I2C write phase for combined write-read transfer.

 - static `rx_err_t` `internal_riic_read_phase` (volatile `rx_riic_regs_t` *riic, const `i2c_device_addr_t` device_addr, `uint8_t` *read_data, const `uint16_t` read_length)

Execute I2C read phase for combined write-read transfer.

 - static `rx_err_t` `internal_riic_validate_init` (const `riic_channel_t` channel, const `uint32_t` frequency_hz, volatile `rx_riic_regs_t` **riic_out)

Initialize RIIC (I2C) channel for controller mode operation.

 - static void `internal_riic_release_module_stop` (const `uint8_t` channel_value)

Release the module-stop bit for the requested RIIC channel.

 - static `rx_err_t` `internal_riic_program_bit_rate` (volatile `rx_riic_regs_t` *const riic, const `uint32_t` frequency_hz)

Program ICBRL/ICBRH/ICMR1..3 for the requested SCL frequency.

 - `rx_err_t` `riic_init` (const `riic_channel_t` channel, const `uint32_t` frequency_hz)

Initialize RIIC channel for I2C controller communication.

 - `rx_err_t` `riic_write` (const `riic_channel_t` channel, const `i2c_device_addr_t` device_addr, const `uint8_t` *data, const `uint16_t` length)

Write data to an I2C peripheral device.

 - `rx_err_t` `riic_read` (const `riic_channel_t` channel, const `i2c_device_addr_t` device_addr, `uint8_t` *data, const `uint16_t` length)

Read data from an I2C peripheral device.

 - `rx_err_t` `riic_write_read` (const `riic_channel_t` channel, const `i2c_device_addr_t` device_addr, const `uint8_t` *write_data, const `uint16_t` write_length, `uint8_t` *read_data, const `uint16_t` read_length)

- Combined write-then-read I2C transaction (register read).
- `rx_err_t riic_init_peripheral` (const `riic_channel_t` channel, const `i2c_device_addr_t` device_addr)
 - Initialize RIIC channel in peripheral (device) mode.
- `rx_err_t riic_peripheral_read` (const `riic_channel_t` channel, `uint8_t` *data, const `uint16_t` max_length, `uint16_t` *bytes_read)
 - Read bytes written by the I2C controller to this peripheral.
- `rx_err_t riic_peripheral_write` (const `riic_channel_t` channel, const `uint8_t` *data, const `uint16_t` length)
 - Write bytes for the I2C controller to read from this peripheral.
- `rx_err_t riic_deinit_peripheral` (const `riic_channel_t` channel)
 - Deinitialize an RIIC channel that was initialized in peripheral mode.

Variables

- static const char *const `s_tag` = "RIIC"
 - Logging tag for RIIC driver messages.
- static const `riic_recovery_pins_t` `k_riic_recovery_pins` [`k_riic_max_channels`]
 - Per-channel recovery pin lookup.
- static `riic_channel_mode_t` `s_riic_channel_mode` [`k_riic_max_channels`]
 - Per-channel RIIC mode tracking array.

8.105.1 Detailed Description

RIIC (I2C) Driver Implementation for RX72N.

Production-grade implementation of the I2C Bus Interface (RIIC) peripheral driver for the RX72N microcontroller. This driver provides controller-mode I2C communication with support for standard (100 kHz), fast (400 kHz), and fast-plus (1 MHz) modes.

8.105.1.1 Module Architecture

8.105.1.2 I2C Protocol Implementation

This driver implements the I2C protocol in controller mode:

8.105.1.2.1 Write Transaction

8.105.1.2.2 Read Transaction

8.105.1.2.3 Write-Read Transaction (Register Read)

8.105.1.3 Bit Rate Calculation

The I2C clock frequency is calculated from PCLKB (60 MHz) as:

$$f_{SCL} = \frac{f_{PCLKB}}{(ICBRL + ICBRH + 2) \times 2^{CKS}}$$

For simplified calculation with 50% duty cycle (ICBRL = ICBRH):

$$\text{divisor} = \frac{f_{PCLKB}}{f_{SCL} \times 3}$$

Mode	Speed	Divisor	Actual Rate
Standard	100 kHz	200	100.0 kHz
Fast	400 kHz	50	400.0 kHz
Fast Plus	1 MHz	20	1.00 MHz

8.105.1.4 Memory Map (Chapter 42 - RIIC)

Channel	Base Address	Pin SCL	Pin SDA	Module Stop Bit
RIIC0	0x00088300	P16	P17	MSTPB21 (MSTPCRB b21)
RIIC1	0x00088320	P21	P20	MSTPB20 (MSTPCRB b20)
RIIC2	0x00088340	P66	P67	MSTPC17 (MSTPCRC b17)

8.105.1.5 Register Offsets (per channel)

Offset	Register	Description
0x00	ICCR1	Control Register 1
0x01	ICCR2	Control Register 2
0x02	ICMR1	Mode Register 1
0x03	ICMR2	Mode Register 2
0x04	ICMR3	Mode Register 3
0x10	ICBRL	Bit Rate Low period
0x11	ICBRH	Bit Rate High period
0x12	ICDRT	Transmit Data Register
0x13	ICDRR	Receive Data Register

8.105.1.6 Error Handling

The driver provides comprehensive error detection:

- `k'rx'err'null'ptr`: nullptr passed to function
- `k'rx'err'invalid'arg`: Invalid channel, address, or frequency
- `k'rx'err'invalid'state`: Channel not initialized
- `k'rx'err'timeout`: Bus busy or operation timeout
- `k'rx'err'nack`: Peripheral did not acknowledge

8.105.1.7 NASA Power of 10 Compliance

Rule	Implementation
Rule 1	No goto, setjmp, or recursion - sequential error handling
Rule 2	Bounded loops - all loops use k_riic_timeout_us timeout
Rule 3	No dynamic memory - static channel state array
Rule 4	Short functions - each < 60 lines
Rule 5	Validation - RX_CHECK_NULL_PTR, RX_CHECK_RANGE_TAG
Rule 6	Smallest scope - local variables declared at point of use
Rule 7	All return values checked - RX_RETURN_ON_ERROR
Rule 8	Limited preprocessor - only RX_CHECK macros
Rule 9	Function pointers via interface pattern (not used here)
Rule 10	Compiles with -Wall -Wextra -Werror

8.105.1.8 SOLID Principles Compliance

Principle	Implementation
S Single Responsibility	Driver handles only RIIC I2C operations
O Open/Closed	Supports multiple frequencies via parameter
L Liskov Substitution	Consistent error codes across all functions
I Interface Segregation	Separate read/write/write-read APIs
D Dependency Inversion	Uses hardware.h abstraction for registers

Thread Safety

This module is NOT thread-safe. Each RIIC channel should be accessed by only one thread at a time. If multiple threads need I2C access, provide external synchronization (mutex/semaphore) at the application level.

Example: Read Temperature Sensor

```
// Initialize RIIC0 at 400 kHz (Fast mode)
riic_channel_t channel = {.value = 0};
rx_err_t err = riic_init(channel, 400000);
if (err != k_rx_ok) {
    handle_error(err);
    return;
}

// Read 2 bytes from temperature sensor at address 0x48
i2c_device_addr_t sensor_addr = {.value = 0x48};
uint8_t temp_reg = 0x00; // Temperature register
uint8_t temp_data[2];

err = riic_write_read(channel, sensor_addr, &temp_reg, 1, temp_data, 2);
if (err == k_rx_ok) {
    int16_t raw_temp = (temp_data[0] << 8) | temp_data[1];
    float celsius = raw_temp * 0.0625f; // LM75 resolution
}
```

8.105.2 Data Structure Documentation

8.105.2.1 struct riic_recovery_pins_t

Channel-specific port + pin info for bit-bang bus recovery.

Indexed by riic channel number. A zero port_base entry means no recovery table entry has been provided for that channel (skipped at runtime). Only RIIC1 is currently populated because only the IMU uses RIIC; add RIIC0/RIIC2 entries when those channels are activated.

Definition at line [604](#) of file [riic.c](#).

Collaboration diagram for riic_recovery_pins_t:

Data Fields

uintptr_t	odr0_addr	ODR register address for N-ch open-drain selection
uint8_t	odr_mask	ODR bit mask for N-ch open-drain on SCL + SDA pin pair
uintptr_t	port_base	rx_port_regs_t* base address for the port holding SCL+SDA
uint8_t	scl_bit	SCL pin bit position within the port (0-7)
uint8_t	sda_bit	SDA pin bit position within the port (0-7)

8.105.2.2 struct riic'saved'cfg't

Wait for I2C bus to become idle (not busy).

Polls the BBSY (Bus Busy) bit in ICCR2 until the bus is free or timeout occurs. This function must be called before starting a new I2C transaction to ensure no other controller is using the bus (multi-controller arbitration).

8.105.2.3 Bus Busy Detection

The BBSY bit is set when:

- A START condition is detected on the bus
- The controller has issued a START condition

The BBSY bit is cleared when:

- A STOP condition is detected on the bus
- Bus arbitration is lost

8.105.2.4 Timeout Calculation

At 100 kHz (slowest mode), maximum byte transfer time:

- 9 bits per byte (8 data + 1 ACK) x 10 us = 90 us
- For 256 bytes (max transfer): 256 x 90 us = 23 ms

The 10 ms timeout (k_riic_timeout_us) provides margin for typical operations while catching true bus-stuck conditions.

Precondition

riic != nullptr

RIIC channel must be initialized and enabled

Postcondition

Bus is idle if `k_rx_ok` returned

Note

This is a blocking function - polls in tight loop.

Timeout is ~10ms at `k_riic_timeout_us` iterations.

Warning

In multi-controller systems, bus may become busy again immediately after this function returns - caller should proceed quickly.

NASA Power of 10 Compliance

- Rule 2: [OK] Bounded loop with `k_riic_timeout_us` maximum iterations
- Rule 5: [OK] nullptr check via `RX_CHECK_NULL_PTR`

Snapshot of RIIC config registers preserved across IICRST pulses

IICRST resets ICBRH/ICBRL/ICMR1/ICMR2/ICMR3 to power-on defaults. The recovery sequence saves these before pulsing IICRST and restores them after, so the post-recovery RIIC keeps the configured baud rate and mode bits.

Since

Version 1.0.0

Definition at line [1133](#) of file [riic.c](#).

Collaboration diagram for `riic_saved_cfg_t`:

Data Fields

uint8_t	icbrh	ICBRH (high-period bit-rate divisor).
uint8_t	icbrl	ICBRL (low-period bit-rate divisor).
uint8_t	icmr1	ICMR1 (mode register 1).
uint8_t	icmr2	ICMR2 (mode register 2).

8.105.3 Enumeration Type Documentation

8.105.3.1 riic`address`bits` t

enum [riic_address_bits_t](#) : uint8_t

I2C 7-bit address formatting constants.

I2C uses a 7-bit address plus a read/write direction bit in the first byte after START. The address is left-shifted by 1 and OR'd with the direction bit.

Address Byte Format

```

Bit:  7  6  5  4  3  2  1  0
      +-----+ +- R/W (0=Write, 1=Read)
      +- 7-bit Address

```

Address Calculation

- Write to 0x50: (0x50 << 1) | 0 = 0xA0
- Read from 0x50: (0x50 << 1) | 1 = 0xA1

Invariant

`k_riic_addr_max_7bit == 127` (I2C spec: addresses 0x00-0x7F)

```

// Format a write address byte for device at 0x50
riic_device_addr_t dev = {.value = 0x50};
uint8_t addr_byte = (uint8_t)((dev.value « k_riic_addr_shift) | k_riic_addr_write_bit);

```

See also

[internal_write_byte\(\)](#) Uses these constants to format address bytes

[riic_write\(\)](#) Passes formatted address bytes during write transactions

Enumerator

<code>k_riic_addr_shift</code>	Left shift amount for 7-bit address
<code>k_riic_addr_write_bit</code>	R/W bit value for write operation
<code>k_riic_addr_read_bit</code>	R/W bit value for read operation
<code>k_riic_addr_max_7bit</code>	Maximum valid 7-bit address (0x7F)

Definition at line 545 of file [riic.c](#).

```

00545     : uint8_t {
00546     k_riic_addr_shift    = 1, /**< Left shift amount for 7-bit address */
00547     k_riic_addr_write_bit = 0, /**< R/W bit value for write operation */
00548     k_riic_addr_read_bit  = 1, /**< R/W bit value for read operation */
00549     k_riic_addr_max_7bit  = 127, /**< Maximum valid 7-bit address (0x7F) */
00550 } riic_address_bits_t;

```

8.105.3.2 riic`bit`rate`t

```
enum riic_bit_rate_t : uint8_t
```

Bit rate calculation constants for ICBRL/ICBRH registers.

These constants are used in `internal_calculate_bit_rate()` to compute the correct ICBRL and ICBRH register values for a target frequency.

Calculation Formula

For 50% duty cycle (ICBRL = ICBRH = divisor):

$$\text{divisor} = \frac{f_{PCLKB}}{f_{target} \times 3}$$

Where the factor of 3 accounts for:

- SCL high period (ICBRH + 1) cycles
- SCL low period (ICBRL + 1) cycles
- Internal synchronization overhead

Enumerator

k_riic_cks_100khz	ICMR1.CKS[2:0] = 100b for 100 kbps @ 60 MHz PCLK
k_riic_icbrh_100k	ICBRH count, HUM Table 42.5
k_riic_icbtl_100k	ICBRL count, HUM Table 42.5
k_riic_cks_400khz	ICMR1.CKS[2:0] = 010b for 400 kbps @ 60 MHz PCLK

00388     k_riic_icbtl_1m = 29U, /**< ICBRL count, HUM Table 42.5 */
00389     k_riic_cks_shift = 4U, /**< ICMR1 bit position of CKS[0] (CKS is bits [6:4]) */
00390 } riic_bit_rate_t;
```

8.105.3.3 riic`channel`mode`t

```
enum riic_channel_mode_t : uint8_t
```

Per-channel RIIC initialization mode.

Tracks whether each RIIC channel has been initialized, and if so, whether it was initialized for controller or peripheral operation. This prevents peripheral-mode APIs from running on a controller-initialized channel and vice-versa, satisfying the Liskov Substitution Principle for RIIC API implementations.

Invariant

Set only by [riic_init\(\)](#) (controller) and [riic_init_peripheral\(\)](#) (peripheral)

Reset to k_riic_mode_uninitialized by [riic_deinit_peripheral\(\)](#) on success

Since

Version 1.0.0

Enumerator

k_riic_mode_uninitialized	Channel not yet initialized
k_riic_mode_controller	Initialized by riic_init() – controller mode
k_riic_mode_peripheral	Initialized by riic_init_peripheral() – peripheral mode

Definition at line 872 of file [riic.c](#).

```
00872      : uint8_t {
00873  k_riic_mode_uninitialized = 0x00u, /**< Channel not yet initialized */
00874  k_riic_mode_controller   = 0x01u, /**< Initialized by riic_init() -- controller mode */
00875  k_riic_mode_peripheral   = 0x02u, /**< Initialized by riic_init_peripheral() -- peripheral mode */
00876 } riic_channel_mode_t;
```

8.105.3.4 riic`channel`num`t

```
enum riic_channel_num_t : uint8_t
```

RIIC channel identifiers for switch statement dispatch.

Provides named constants for channel selection in [internal_get_riic_base\(\)](#). Using enums instead of raw integers ensures type safety and improves code readability in switch statements.

Channel to Pin Mapping

Channel	SCL Pin	SDA Pin	Base Address
RIIC0	P16	P17	0x00088300
RIIC1	P21	P20	0x00088320
RIIC2	P66	P67	0x00088340

Invariant

Values are contiguous starting from 0 and match hardware channel indices

```
// Select channel 0 base address
volatile rx_riic_regs_t* regs = internal_get_riic_base(k_riic_channel_0);
```

[riic_constants_t](#) For [k_riic_max_channels](#) bound used with these values

Enumerator

k_riic_channel_0	RIIC channel 0 (P16/SCL0, P17/SDA0)
k_riic_channel_1	RIIC channel 1 (P21/SCL1, P20/SDA1)
k_riic_channel_2	RIIC channel 2 (P66/SCL2, P67/SDA2)

Definition at line 285 of file [riic.c](#).

```
00285         : uint8_t {
00286   k_riic_channel_0 = 0, /**< RIIC channel 0 (P16/SCL0, P17/SDA0) */
00287   k_riic_channel_1 = 1, /**< RIIC channel 1 (P21/SCL1, P20/SDA1) */
00288   k_riic_channel_2 = 2, /**< RIIC channel 2 (P66/SCL2, P67/SDA2) */
00289 } riic_channel_num_t;
```

8.105.3.5 `riic_constants_t`

```
enum riic\_constants\_t : uint32_t
```

RIIC channel count, timeout, and transfer limit constants.

General-purpose constants for RIIC driver operation including channel limits, timeout values, and transfer size constraints.

Timeout Selection

The 10ms timeout provides sufficient margin for:

- Standard mode: 100 kHz = 10us/bit, 90us/byte -> 10ms = ~111 bytes
- Fast mode: 400 kHz = 2.5us/bit, 22.5us/byte -> 10ms = ~444 bytes
- Fast Plus: 1 MHz = 1us/bit, 9us/byte -> 10ms = ~1111 bytes

Invariant

`k_riic_max_channels == 3` (hardware limitation)
`k_riic_max_transfer_length == 256` (single-byte length limit)

Enumerator

<code>k_riic_max_channels</code>	Total RIIC channels: RIIC0, RIIC1, RIIC2
----------------------------------	--

k_riic_timeout_us	Busy-loop iteration budget for I2C flag waits. Each iteration reads ICSR2/ICCR2 + decrements a volatile counter (~10 cycles @ 240 MHz ~ = 40 ns), so 25k iters ~ = 1 ms wall time – enough to cover a byte at 100 kHz (90 us) with 10x slack for clock stretching. Kept below the 900 ms IWDT window even if a 256-byte transfer stacks up 256 per-byte timeouts back-to-back.
k_riic_timeout_zero	Timeout counter expired sentinel value
k_riic_length_zero	Zero-length transfer (invalid) sentinel
k_riic_register_clear	Zero value used to clear hardware registers
k_riic_last_index_offset	Offset to calculate last byte index from length
k_riic_max_transfer_length	Maximum bytes per transfer operation

Definition at line 242 of file [riic.c](#).

```

00242         : uint32_t {
00243     k_riic_max_channels      = 3,    /**< Total RIIC channels: RIIC0, RIIC1, RIIC2 */
00244     k_riic_timeout_us       = 25000, /**< Busy-loop iteration budget for I2C flag waits.
00245                                     * Each iteration reads ICSR2/ICCR2 + decrements a
00246                                     * volatile counter (~10 cycles @ 240 MHz ~ = 40 ns),
00247                                     * so 25k iters ~ = 1 ms wall time -- enough to
00248                                     * cover a byte at 100 kHz (90 us) with 10x slack
00249                                     * for clock stretching. Kept below the 900 ms IWDT
00250                                     * window even if a 256-byte transfer stacks up
00251                                     * 256 per-byte timeouts back-to-back. */
00252     k_riic_timeout_zero     = 0,    /**< Timeout counter expired sentinel value */
00253     k_riic_length_zero      = 0,    /**< Zero-length transfer (invalid) sentinel */
00254     k_riic_register_clear   = 0,    /**< Zero value used to clear hardware registers */
00255     k_riic_last_index_offset = 1,    /**< Offset to calculate last byte index from length */
00256     k_riic_max_transfer_length = 256, /**< Maximum bytes per transfer operation */
00257 } riic_constants_t;

```

8.105.3.6 riic_frequency_t

```
enum riic\_frequency\_t : uint32_t
```

Supported I2C bus frequencies (Hz).

I2C standard defines three speed grades. This driver supports all three modes with appropriate bit rate register configuration.

Timing Characteristics (at PCLKB = 60 MHz)

Mode	Frequency	Bit Time	Byte Time	Max Cable
Standard	100 kHz	10 us	90 us	~1 meter
Fast	400 kHz	2.5 us	22.5 us	~0.5 m
Fast Plus	1 MHz	1 us	9 us	~0.2 m

Invariant

Only these three discrete values are accepted by [riic_init\(\)](#)

```

// Initialize channel 0 at standard (100 kHz) mode
riic_channel_t ch = {.value = 0};
rx_err_t err = riic_init(ch, k_riic_freq_100khz);

```

See also

[riic_init\(\)](#) Validates frequency_hz against these enum values

[internal_calculate_bit_rate\(\)](#) Uses frequency to compute ICBRL/ICBRH

Note

Fast Plus mode requires pull-up resistors < 1kOhm for proper rise time.

Enumerator

k_riic_freq_100khz	Standard mode: 100 kHz (Sm)
k_riic_freq_400khz	Fast mode: 400 kHz (Fm)
k_riic_freq_1mhz	Fast mode plus: 1 MHz (Fm+)

Definition at line 345 of file [riic.c](#).

```
00345      : uint32_t {
00346  k_riic_freq_100khz = 100000, /**< Standard mode: 100 kHz (Sm) */
00347  k_riic_freq_400khz = 400000, /**< Fast mode: 400 kHz (Fm) */
00348  k_riic_freq_1mhz   = 1000000, /**< Fast mode plus: 1 MHz (Fm+) */
00349 } riic_frequency_t;
```

8.105.3.7 riic_icmr1_values_t

```
enum riic_icmr1_values_t : uint8_t
```

ICMR1 (Mode Register 1) configuration values.

ICMR1 configures the controller/peripheral mode and addressing type. For STAR project, we use controller mode with 7-bit addressing.

ICMR1 Register Layout (Bits 7-4)

Bit	Name	Description
6-4	CKS	Clock divider (0-7)
3	BCWP	BC write protect
2-0	BC	Bit counter

Enumerator

k_riic_icmr1_controller_7bit	CKS=0, BCWP=1, 7-bit addressing; MTWP=0 keeps MST/↵ TRS read-only so the hardware START/STOP FSM drives them, per HUM section 42.2.3. MTWP=1 was tried and caused "Start condition failed" on every transaction because iccr2=MST TRS pre-writes the mode bits before START fires and the FSM gets desynced.
------------------------------	--

Definition at line 407 of file [riic.c](#).

```
00407      : uint8_t {
00408  k_riic_icmr1_controller_7bit =
00409      0x08, /**< CKS=0, BCWP=1, 7-bit addressing; MTWP=0 keeps MST/TRS read-only so the hardware START/STOP
               FSM drives them, per HUM section 42.2.3. MTWP=1 was tried and caused "Start condition failed" on every transaction
               because iccr2=MST|TRS pre-writes the mode bits before START fires and the FSM gets desynced. */
00410 } riic_icmr1_values_t;
```

8.105.3.8 riic`icmr2`values`t

```
enum riic_icmr2_values_t : uint8_t
```

ICMR2 (Mode Register 2) configuration values.

ICMR2 configures hardware timeout detection and SDA output hold-time delay. The STAR project disables hardware timeout (TMOE = 0) because bus-busy detection is handled in software by [internal_wait_bus_ready\(\)](#) using the `k_riic_timeout_us` countdown. The SDA output delay is also left at zero (no additional hold time) since the pull-up resistors on the target PCB provide adequate signal integrity at all supported speeds.

8.105.3.9 ICMR2 Register Bit Layout

Bit	Name	Function	Value Used
7	TMOH	Timeout detection (high period)	0 (off)
6	TMOL	Timeout detection (low period)	0 (off)
5	TMOE	Timeout enable	0 (off)
4:↔ 3	SDDL	SDA output hold-time delay	0 (none)
2	DLCS	SDA delay clock source	0
1:↔ 0	-	Reserved	0

Invariant

`k_riic_icmr2_default == 0`; writing 0x00 leaves all ICMR2 control bits in their hardware-reset state (timeouts off, no SDA delay)

```
// Apply default ICMR2 configuration during RIIC channel initialization
volatile rx_riic_regs_t* riic = internal_get_riic_base(k_riic_channel_0);
riic->icmr2 = k_riic_icmr2_default;
```

See also

[riic_init\(\)](#) Applies this value during channel initialization

[k_riic_timeout_us](#) Software timeout used instead of hardware TMOE

Enumerator

<code>k_riic_icmr2_default</code>	No hardware timeout, no SDA delay
-----------------------------------	-----------------------------------

Definition at line 447 of file [riic.c](#).

```
00447 : uint8_t {
00448 k_riic_icmr2_default = 0, /**< No hardware timeout, no SDA delay */
00449 } riic_icmr2_values_t;
```

8.105.3.10 riic_icmr3_bits_t

```
enum riic_icmr3_bits_t : uint8_t
```

ICMR3 (Mode Register 3) ACK/NACK control bit definitions.

ICMR3 controls ACK/NACK transmission during receive operations. The key field is ACKBT (Acknowledgement Bit), which determines whether the controller sends an ACK or NACK after each received byte.

8.105.3.11 ACK/NACK Signalling Rules (I2C Specification)

- Set ACKBT=0 (clear bit) to send ACK: instructs the peripheral to continue transmitting; used for all bytes except the last in a read transfer.
- Set ACKBT=1 (set bit) to send NACK: instructs the peripheral to stop transmitting; must be applied before clocking in the final byte so that the NACK is sent automatically at the correct clock edge.

8.105.3.12 ICMR3 Register Bit Layout (relevant bits)

Bit	Name	Function
4	ACKWP	ACKBT write protect (1=writable)
3	ACKBT	ACK/NACK bit to transmit

Invariant

k_riic_icmr3_ackbt_pos == 3 matches the RX72N hardware bit position for ACKBT in ICMR3; changing this breaks ACK/NACK control

k_riic_icmr3_ackbt_mask == (1U << 3) == 0x08; derived from pos

k_riic_icmr3_ackwp_pos == 4 matches the RX72N hardware bit position for ACKWP; changing this silently breaks ACKBT writes

k_riic_icmr3_ackwp_mask == (1U << 4) == 0x10; derived from pos

Note

NACK must be sent before reading the last byte to signal to the peripheral that the transfer is complete per I2C specification.

ACKWP=1 is REQUIRED before any ACKBT write. Without it, writes to ACKBT are silently ignored – the controller keeps ACKing every byte, the peripheral never sees NACK, and STOP times out with the bus locked. ACKWP=1 is set in [riic_init\(\)](#) as part of k_riic_icmr3_init.

```
// Prepare to NACK the last byte in a read transfer (ACKWP must already be 1)
volatile rx_riic_regs_t* riic = internal_get_riic_base(k_riic_channel_0);
riic->icmr3 |= k_riic_icmr3_ackbt_mask; // Set ACKBT=1 -> send NACK
```

```
// Re-enable ACK for subsequent transfers
riic->icmr3 &= (uint8_t)~k_riic_icmr3_ackbt_mask; // Set ACKBT=0 -> send ACK
```

```

8.105.3.13 riic`module`stop`bits`

enum [riic_module_stop_bits_t](#) : uint8_t

RIIC module stop bit positions in MSTPCRB (RIIC0/1) and MSTPCRC (RIIC2).

The RX72N uses a module stop mechanism to reduce power consumption. RIIC0 and RIIC1 module stop bits reside in MSTPCRB; RIIC2 resides in MSTPCRC (manual Ch11, p408-410). RIIC channels must be enabled (bit cleared) before use.

Module Enable Procedure

1. Unlock register protection: `PRCR = k_rx_prcr_unlock_prc1_prc3`
2. RIIC0: `MSTPCRB &= ~(1 << k_riic_mstpb_riic0)` RIIC1: `MSTPCRB &= ~(1 << k_riic_mstpb_riic1)` RIIC2: `MSTPCRC &= ~(1 << k_riic_mstpc_riic2)`
3. Lock register protection: `PRCR = k_rx_prcr_lock`

See also

`rx_register_protection.h` for PRCR register access

Enumerator

<code>k_riic_mstpb_riic0</code>	MSTPCRB bit 21: RIIC0 module stop control (manual p408)
<code>k_riic_mstpb_riic1</code>	MSTPCRB bit 20: RIIC1 module stop control (manual p408)
<code>k_riic_mstpc_riic2</code>	MSTPCRC bit 17: RIIC2 module stop control (manual p410)
<code>k_riic_mstpb_bit_value</code>	Single bit value for bit manipulation

Definition at line 310 of file `riic.c`.

```
00310      : uint8_t {
00311  k_riic_mstpb_riic0    = 21, /**< MSTPCRB bit 21: RIIC0 module stop control (manual p408) */
00312  k_riic_mstpb_riic1    = 20, /**< MSTPCRB bit 20: RIIC1 module stop control (manual p408) */
00313  k_riic_mstpc_riic2    = 17, /**< MSTPCRC bit 17: RIIC2 module stop control (manual p410) */
00314  k_riic_mstpb_bit_value = 1,  /**< Single bit value for bit manipulation */
00315 } riic_module_stop_bits_t;
```

8.105.3.14 riic peripheral reg constants

enum `riic_peripheral_reg_constants_t` : `uint8_t`

Register bit-field constants for peripheral mode configuration.

Bit field values used when configuring RIIC for peripheral (device) mode. In peripheral mode the RX72N responds to an external I2C controller (RPi5). All values fit in `uint8_t` since they are 8-bit register constants.

Since

Version 1.0.0

Enumerator

<code>k_riic_periph_timeout_us</code>	1ms timeout for TDRE poll in write
---------------------------------------	------------------------------------

Definition at line 2821 of file [riic.c](#).

```
02821      : uint16_t {
02822 k_riic_periph_timeout_us = 1000, /**< 1ms timeout for TDRE poll in write */
02823 } riic_peripheral_size_constants_t;
```

8.105.3.16 riic`recovery`constants`

```
enum riic_recovery_constants_t : uint32_t
```

Bit-bang bus-recovery timing and ODR register addresses.

When a peripheral on the bus holds SDA/SCL low, IICRST alone cannot clear a stuck BBSY because the peripheral reset does not toggle external SCL edges. [internal_riic_bit_bang_recover\(\)](#) temporarily drops PMR, drives SCL low-high 9 times to walk any stuck peripheral through a byte + ACK, generates a manual STOP, then hands the pads back to the RIIC peripheral.

ODR0 register addresses per port (RX72N HW manual Table 22.2): Port 2 ODR0 @ 0x0008C084 – pin pair bits (P20 -> bit1, P21 -> bit3)

Enumerator

<code>k_riic_recov_cycles</code>	9 SCL edges: flush one byte + ACK
<code>k_riic_recov_half_us</code>	5 us half-period -> ~100 kHz SCL
<code>k_riic_recov_cpu_mhz</code>	ICLK frequency for busy-wait math
<code>k_riic_recov_stop_us</code>	STOP condition SDA-low-then-high delay
<code>k_riic_port2_odr0_addr</code>	Port 2 ODR0 (P20/P21 N-ch open-drain)

Definition at line 586 of file [riic.c](#).

```
00586      : uint32_t {
00587 k_riic_recov_cycles    = 9U,      /**< 9 SCL edges: flush one byte + ACK */
00588 k_riic_recov_half_us  = 5U,      /**< 5 us half-period -> ~100 kHz SCL */
00589 k_riic_recov_cpu_mhz  = 240U,    /**< ICLK frequency for busy-wait math */
00590 k_riic_recov_stop_us  = 5U,      /**< STOP condition SDA-low-then-high delay */
00591 k_riic_port2_odr0_addr = 0x0008C084U, /**< Port 2 ODR0 (P20/P21 N-ch open-drain) */
00592 } riic_recovery_constants_t;
```

8.105.4 Function Documentation

8.105.4.1 internal_calculate_bit_rate()

```
rx_err_t internal_calculate_bit_rate (
    const uint32_t frequency_hz,
    uint8_t * icbtl,
    uint8_t * icbrh,
    uint8_t * cks_field) [static]
```

Calculate RIIC bit rate register values for target frequency.

Computes the ICBRL and ICBRH register values to achieve the desired I2C bus frequency. Uses a simplified calculation assuming 50% duty cycle (equal high and low periods).

8.105.4.2 Calculation Algorithm

The RX72N RIIC bit rate formula (from Chapter 42):

$$f_{SCL} = \frac{f_{PCLKB}}{(ICBRL + 1) + (ICBRH + 1) + \text{sync}}$$

Simplified for 50% duty cycle (ICBRL = ICBRH):

$$\text{divisor} = \frac{f_{PCLKB}}{f_{target} \times 3}$$

8.105.4.3 Example Calculations (PCLKB = 60 MHz)

Target	Calculation	Divisor	Actual Rate
100 kHz	60M / (100k x 3)	200	100.0 kHz
400 kHz	60M / (400k x 3)	50	400.0 kHz
1 MHz	60M / (1M x 3)	20	1.00 MHz

Precondition

```
icbtl != nullptr
icbrh != nullptr
frequency_hz is a supported I2C frequency
```

Postcondition

```
*icbtl contains the low-period divisor (1-255)
*icbrh contains the high-period divisor (1-255)
*icbtl == *icbrh (50% duty cycle)
```

Note

Uses PCLKB (60 MHz) as the source clock per RX72N specification.
For asymmetric duty cycle, manually set ICBRL != ICBRH after init.

Warning

Frequencies outside 100 kHz - 1 MHz may produce out-of-range divisors.

8.105.4.4 `internal_get_riic_base()`

```
volatile rx_riic_regs_t * internal_get_riic_base (
    const uint8_t channel) [static]
```

Get RIIC channel register base address from channel number.

Maps an RIIC channel number (0-2) to its corresponding hardware register base address using a compile-time-dispatched switch statement. This function is the single point of truth for the channel-to-address mapping and provides a clean abstraction between the logical channel index used throughout the driver and the physical memory-mapped peripheral addresses defined by the RX72N hardware.

8.105.4.5 Channel-to-Address Mapping

The three RIIC channels are located at fixed, evenly spaced addresses in the RX72N peripheral address space (0x00088300, 0x00088320, 0x00088340). Each block is 32 bytes in size and contains all control, status, bit-rate, and data registers for one channel.

8.105.4.6 Memory Map

Channel	Accessor	Base Address	Register Block Size
0	riic0()	0x00088300	32 bytes
1	riic1()	0x00088320	32 bytes
2	riic2()	0x00088340	32 bytes

8.105.4.7 Why Return NULL for Invalid Channel

Returning nullptr for an out-of-range channel allows every caller to perform a single null-pointer check with `RX_CHECK_NULL_PTR` rather than duplicating range validation logic. This pattern is consistent with [rx_port_get_base\(\)](#) in the GPIO driver.

Precondition

- channel must be less than `k_riic_max_channels` (3); values ≥ 3 yield nullptr
- caller must have verified that the corresponding RIIC module stop bit in `MSTPCRB` has been cleared (module enabled) before using the returned pointer

Postcondition

- returned pointer is non-NULL if and only if channel is 0, 1, or 2
- returned pointer, when non-NULL, is aligned to the RIIC peripheral register block boundary as required by the RX72N hardware specification

Note

- This function does NOT validate the channel - the caller is responsible for ensuring the value is in range before calling
- The return type is volatile to prevent the compiler from optimizing away hardware register reads or writes through the returned pointer

Performance:

O(1) - simple switch statement with a direct return per case

Example:

```
// Look up the register base for RIIC channel 1 and send a START condition
volatile rx_riic_regs_t* riic = internal_get_riic_base(k_riic_channel_1);
if (riic == nullptr) {
    return k_rx_err_invalid_arg;
}
riic->iccr2 |= k_riic_iccr2_st; // Issue START condition
```

Here is the caller graph for this function:

8.105.4.8 internal_read_byte()

```

rx_err_t internal_read_byte (
    volatile rx_riic_regs_t * riic,
    uint8_t * data,
    const bool send_ack,
    const bool last_byte) [static]

```

Receive single byte from I2C bus.

Reads one byte from the I2C bus and sends ACK or NACK as specified. The ACK/NACK response is configured before reading the byte from the receive register.

8.105.4.9 Reception Sequence

1. Wait for RDRF (Receive Data Register Full) flag
2. Configure ACK/NACK response in ICMR3.ACKBT
3. Read byte from ICDRR (Receive Data Register)
4. Hardware generates ACK/NACK on 9th clock
5. RDRF flag is cleared by read

8.105.4.10 ACK vs NACK Decision

Situation	Response	ACKBT	Purpose
More bytes to read	ACK	0	Continue transfer
Last byte	NACK	1	Signal end of read

8.105.4.11 I2C Read Byte Timing

```

SCL ++ ++ ++ ++ ++ ++ ++ ++ ++ ++
    || || || || || || || ||
    ++ ++ ++ ++ ++ ++ ++ ++ ++ ++
    D7 D6 D5 D4 D3 D2 D1 D0 ACK/NACK
SDA -----+
    Peripheral drives    +- Controller drives ACK/NACK

```

Precondition

```

riic != nullptr
data != nullptr
Controller is in receive mode (address + read bit sent)

```

Postcondition

```

*data contains the received byte
ACK or NACK has been sent to peripheral
RDRF flag is cleared

```

Note

ACK/NACK is configured BEFORE reading ICDRR.
 NACK on last byte is REQUIRED per I2C specification.

Warning

Failure to send NACK on last byte may cause peripheral to continue driving data, corrupting next transaction.

Example: Reading Multiple Bytes

```

for (uint16_t i = 0; i < length; i++) {
    bool send_ack = (i < length - 1); // ACK all except last
    err = internal_read_byte(riic, &buffer[i], send_ack);
    if (err != k_rx_ok) break;
}

```

Here is the caller graph for this function:

8.105.4.13 internal`riic`bit`bang`recover()

```
void internal_riic_bit_bang_recover (
    uint8_t channel) [static]
```

Bit-bang 9 SCL edges + manual STOP to recover an externally-stuck bus.

Called from `internal_wait_bus_ready` when BBSY stays latched even after an IICRST pulse. That combination means an I2C peripheral on the bus (BNO055 or BMP280 in the STAR system) got interrupted mid-byte – e.g. the RX72N reset during a previous transaction – and is still holding SDA low waiting to finish sending the remaining bits of its byte + ACK.

IICRST only resets the RIIC controller side; it does not toggle SCL on the wire, so it cannot unstick an external peripheral. The only software path that clears this is to physically wiggle SCL from the MCU pad – which requires handing the pad from RIIC back to GPIO long enough to clock out a full byte + ACK + STOP.

Sequence:

1. Drop PMR -> pads are GPIO again, RIIC loses them.
2. Enable N-ch open-drain so we cannot drive-fight a peripheral still holding the line low.
3. Drive both lines high, set as output. External pull-ups dominate.

4. 9x { SCL low; wait; SCL high; wait } – one byte + ACK worth of clocks, enough to clock out any peripheral stuck mid-byte.
5. Manual STOP: SDA low -> high with SCL high – tells any peripheral still listening ”transaction over, idle the bus”.
6. Tristate pads, clear open-drain. Leave PMR=0. The caller raises PMR back to 1 AFTER it has reset the RIIC peripheral (IICRST + SOWP dance), so the peripheral hands the pads back already in a ”driving high” state. Raising PMR while the peripheral still has leftover SCLO=SDAO=0 from the previous transaction would glitch the bus low again immediately.

Only RIIC channels with a populated entry in `k_riic_recovery_pins[]` are handled; other channels return silently.

Precondition

MPC PFS values for SCL/SDA were set during channel init and have not been disturbed (we only toggle PMR, not PFS).

Postcondition

PMR for SCL/SDA is CLEARED (pads stay in GPIO mode, tristated). Caller must reset the RIIC peripheral and then raise PMR.

PDR bits for SCL/SDA are cleared (tristated).

NASA Power of 10 Compliance

- Rule 2: bounded loop (`k_riic_recov_cycles = 9`)
- Rule 5: channel bounds check + `port_base != 0` validation

8.105.4.14 internal_riic`bit`bang`recovery`sequence()

```

void internal_riic_bit_bang_recovery_sequence (
    volatile rx_riic_regs_t *const riic,
    const riic_saved_cfg_t *const saved) [static]

```

Bit-bang last-resort bus recovery + peripheral reset + handback.

Walks the bus through 9 SCL edges + manual STOP via GPIO bit-bang to release a peripheral holding SDA low from an aborted transaction across an MCU reboot (verified on BNO055 against the production STAR PCB). Critical ordering preserved: bit-bang leaves PMR=0 (pads still GPIO), peripheral reset runs while pads are GPIO, then handback raises PMR=1 with the SOWP dance already done so the lines stay high-Z.

Parameters

in	riic	RIIC peripheral base (must be non-null)
in	saved	Pre-recovery config snapshot (used for restore)

Precondition

riic and saved non-null; bus has refused to clear via IICRST alone

Postcondition

Pads handed back to the peripheral with config restored

8.105.4.16 internal`riic`channel`from`base()

```

uint8_t internal_riic_channel_from_base (
    const volatile rx_riic_regs_t * riic)  [static]
  
```

Resolve a RIIC register pointer to its channel number.

Compares the pointer against the three RIIC base addresses. Returns k_riic_max_channels (sentinel) if the pointer does not match any channel, which callers treat as "skip bit-bang recovery".

Definition at line 636 of file [riic.c](#).

```

00637 {
00638     const uintptr_t base = (uintptr_t)riic;
00639     if (base == (uintptr_t)k_riic0_base_addr) {
00640         return (uint8_t)k_riic_channel_0;
00641     }
  
```

```

00642 if (base == (uintptr_t)k_riic1_base_addr) {
00643     return (uint8_t)k_riic_channel_1;
00644 }
00645 if (base == (uintptr_t)k_riic2_base_addr) {
00646     return (uint8_t)k_riic_channel_2;
00647 }
00648 return (uint8_t)k_riic_max_channels;
00649 }

```

Here is the caller graph for this function:

8.105.4.17 internal_riic_force_fsm_reset()

```

void internal_riic_force_fsm_reset (
    volatile rx_riic_regs_t * riic) [static]

```

Raise PMR so the RIIC peripheral takes the pads back.

Companion to [internal_riic_bit_bang_recover\(\)](#). Call this AFTER the RIIC peripheral has been IICRST-pulsed and put through the SOWP / SCLO / SDAO release dance so its internal output latches are high. Raising PMR while those latches are still 0 would glitch the bus low again immediately and could re-confuse the peripheral we just unstuck.

Precondition

[internal_riic_bit_bang_recover\(\)](#) was just called on the same channel.

The RIIC peripheral has been reset (IICRST cycle + SOWP release).

Postcondition

PMR bits for SCL/SDA are set, pads routed to RIIC peripheral.

Pulse IICRST on a controller-initialized RIIC channel and restore config.

Per RX72N HW manual section 42.2.1, writing 1 to ICCR1.IICRST while ICCR1.ICE=0 performs an internal reset of the RIIC peripheral's FSM without touching the pin mux. That drops any half-completed transaction state – BBSY, MST, TRS, pending SP/RS/ST request bits, NACKF, latched AL, the "dummy read kicked reception" flag – back to idle, which is what we need before a new transaction when an earlier transaction on the same peripheral may have left the FSM partially advanced. The config registers (ICBRH/L, ICMR1..3) are wiped by IICRST, so we restore them from the live values (which were set in [riic_init\(\)](#) and must already be valid since ICE was on before the pulse).

Do NOT substitute this for [riic_init\(\)](#): this helper assumes MSTPCR and MPC/PFS are already set up and that ICE=1 was previously toggled to latch the peripheral out of module-stop. It is a fast pre-transaction FSM scrub, not a cold boot.

Currently unused in the main transaction path – kept as a `[[maybe_unused]]` helper because it is the right escape hatch when the FSM has been observed to get stuck mid-transaction and the bit-bang recovery in [internal_wait_bus_ready\(\)](#) is too heavyweight (it tears down and rebuilds pad direction via PMR, which adds ~100 us versus ~2 us here).

Precondition

ICE was set to 1 earlier (channel previously passed `riic_init`).

Postcondition

ICCR1.ICE = 1, ICCR1.IICRST = 0, ICMR1..3 / ICBRH/L restored, ICSR1 / ICSR2 cleared.

8.105.4.18 `internal_riic_iicrst_with_restore()`

```

void internal_riic_iicrst_with_restore (
    volatile rx\_riic\_regs\_t *const riic,
    const riic\_saved\_cfg\_t *const saved) [static]
```

Pulse IICRST and restore config from a saved snapshot.

Asserts IICRST=1 then deasserts back to configuration state, restores ICBRH/ICBRL/ICMR1/ICMR2 plus ICMR3=`k_riic_icmr3_init` (IICRST also wipes ICMR3, and ACKWP=1 must be restored so reads can NACK the final byte). Clears stale ICSR1/ICSR2 flags before re-enabling ICE=1.

Parameters

in	riic	RIIC peripheral base (must be non-null)
in	saved	Pre-recovery config snapshot

Precondition

[riic](#) and [saved](#) non-null

Postcondition

ICE=1 with saved config and clean status registers

```
bool internal_riic_poll_bbsy_clear (
    volatile rx\_riic\_regs\_t *const riic)  [static]
```

Poll BBSY for up to `k_riic_timeout_us` iterations.

Tight-loop watcher for the Bus Busy bit in ICCR2. Returns true when BBSY clears within the timeout, false otherwise.

Parameters

in	riic	RIIC peripheral base (must be non-null)
----	------	---

Returns

bool true if BBSY observed clear, false on timeout

Precondition

riic non-null

Postcondition

Returns false on timeout

Note

Caller decides recovery action (warn + IICRST or bit-bang).

8.105.4.21 internal_riic_program_bit_rate()

```
rx_err_t internal_riic_program_bit_rate (
    volatile rx\_riic\_regs\_t *const riic,
    const uint32_t frequency_hz) [static]
```

Program ICBRL/ICBRH/ICMR1..3 for the requested SCL frequency.

Looks up CKS / ICBRH / ICBRL via [internal_calculate_bit_rate\(\)](#), then writes the bit-rate registers and registers. CKS is in ICMR1[6:4] and must be written alongside MTWP/BCWP/BC in a single ICMR1 write. ICMR3 = ACKWP | 0 – ACKWP=1 is mandatory so [internal_read_byte\(\)](#) can NACK the final received byte (otherwise STOP after every read times out).

Parameters

in	riic	RIIC peripheral base (must be non-null)
in	frequency_hz	Validated SCL frequency

Returns

`rx_err_t` Error code from [internal_calculate_bit_rate\(\)](#)

Precondition

RIIC peripheral is in IICRST or post-IICRST configuration state

Postcondition

ICBRL/ICBRH/ICMR1/ICMR2/ICMR3 programmed

Here is the caller graph for this function:

8.105.4.22 internal_riic_read_phase()

```

rx_err_t internal_riic_read_phase (
    volatile rx_riic_regs_t * riic,
    const i2c_device_addr_t device_addr,
    uint8_t * read_data,
    const uint16_t read_length) [static]
```

Execute I2C read phase for combined write-read transfer.

Performs the read portion of a write-read (register read) transaction. Issues a repeated START condition (without releasing the bus), then reads data bytes from the peripheral.

8.105.4.23 Transaction Sequence

8.105.4.24 Repeated START vs STOP+START

The repeated START (Sr) is critical for atomic register reads:

- Prevents other controllers from arbitrating between address write and data read
- Ensures peripheral's internal address pointer is still valid
- Required by many I2C peripherals (EEPROMs, sensors, etc.)

8.105.4.25 ACK/NACK Protocol

Per I2C specification, the controller must NACK the last byte to signal end of read. This allows the peripheral to release SDA for the STOP condition.

Precondition

```

riic points to valid, initialized RIIC channel
Write phase has been completed (bus is active)
device_addr.value <= 127
read_data != nullptr
read_length > 0
  
```

Postcondition

```

On success: read_data contains received bytes
On failure: STOP issued, bus released
  
```

Note

```

Does NOT issue STOP on success - caller must issue STOP.
On error, STOP is always issued for bus cleanup.
NACK is automatically sent on last byte.
  
```

8.105.4.26 internal`riic`release`lines()

```
void internal_riic_release_lines (
    volatile rx_riic_regs_t *const riic) [static]
```

Drive the SOWP/SCLO/SDAO release dance after an IICRST pulse.

Forces SCLO=SDAO=1 via SOWP write-protect-clear so the open-drain drivers release the bus (high-Z) on handback to the peripheral.

Parameters

in	riic	RIIC peripheral base (must be non-null)
----	------	---

Precondition

riic non-null and ICE=1

Postcondition

SOWP restored to write-protected

Since

Version 1.0.0

Definition at line 1239 of file [riic.c](#).

```
01240 {
01241     uint8_t iccr1 = riic->iccr1;

8.105.4.27 `internal_riic_release_module_stop()`

```
void internal_riic_release_module_stop (
    const uint8_t channel_value) [static]
```

Release the module-stop bit for the requested RIIC channel.

Wraps the protected-register PRCR unlock/lock around the MSTPCRB/CRC write that releases the channel's clock gate. Channel-to-MSTP-bit mapping mirrors the RX72N HW manual MSTP table.

Parameters

in	channel_value	Validated channel index
----	---------------	-------------------------

Precondition

`channel_value < k_riic_max_channels`

Postcondition

Channel module clock is running

Since

Version 1.0.0

Definition at line 2178 of file [riic.c](#).

```
02179 {
02180     *prcr_reg() = k_rx_prcr_unlock_prc1_prc3;

```
void internal_riic_save_config (
    const volatile rx_riic_regs_t *const riic,
    riic_saved_cfg_t *const saved) [static]
```

Save config registers wiped by an IICRST pulse.

Parameters

in	riic	RIIC peripheral base (must be non-null)
out	saved	Snapshot of ICBRH/ICBRL/ICMR1/ICMR2

Precondition

riic and saved non-null

Postcondition

saved holds the pre-reset register values

Since

Version 1.0.0

Definition at line 1179 of file [riic.c](#).

```
01181 {
01182     saved->icbrh = riic->icbrh;
01183     saved->icbtl = riic->icbtl;
01184     saved->icmr1 = riic->icmr1;

Here is the caller graph for this function:

8.105.4.29 `internal_riic_validate_init()`

```

rx_err_t internal_riic_validate_init (
    const riic_channel_t channel,
    const uint32_t frequency_hz,
    volatile rx_riic_regs_t ** riic_out) [static]

```

Initialize RIIC (I2C) channel for controller mode operation.

Configures an RIIC channel for I2C controller mode communication at the specified bus frequency. This function must be called before any I2C transfers on the channel.

8.105.4.30 Initialization Sequence

1. Validate channel number and frequency
2. Enable RIIC module clock (clear MSTPCRB bit)
3. Reset RIIC internal state (IICRST)
4. Calculate and configure bit rate registers
5. Configure controller mode, 7-bit addressing
6. Enable I2C bus interface (ICE)
7. Mark channel as initialized

8.105.4.31 Module Stop Control

The RIIC peripheral is disabled by default to save power. This function enables the module clock by clearing the appropriate MSTPCRB bit:

Channel	MSTPCRB Bit	Default State
RIIC0	Bit 21	Stopped
RIIC1	Bit 20	Stopped
RIIC2	Bit 19	Stopped

8.105.4.32 Supported Frequencies

Frequency	Mode	Use Case
100 kHz	Standard	Legacy devices
400 kHz	Fast	Most I2C peripherals
1 MHz	Fast Plus	High-speed sensors

Precondition

`channel.value < 3`

`frequency_hz` is one of: 100000, 400000, 1000000

Postcondition

Channel is enabled and ready for I2C transfers

```
s_riic_channel_mode[channel.value] == k_riic_mode_controller
```

Note

This function modifies protected registers (MSTPCRB) using PRCR unlock.

Re-initializing an already initialized channel is allowed.

Pin configuration (MPC) must be done separately if needed.

Warning

Using unsupported frequencies may cause communication failures.

Example

```
// Initialize RIIC0 for Fast mode (400 kHz)
riic_channel_t channel = {.value = 0};
rx_err_t err = riic_init(channel, 400000);
if (err != k_rx_ok) {
    rx_log_error("I2C", "Failed to initialize RIIC0");
}
```

Since

Version 1.0.0

Validate `riic_init` arguments and resolve peripheral base

Checks that channel is in range, frequency is one of the three supported buckets (100k/400k/1M), and resolves the channel to its peripheral base address.

Parameters

in	channel	Channel handle
in	frequency_hz	Requested SCL frequency
out	riic_out	On success, set to the peripheral base

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Inputs valid, <code>*riic_out</code> non-null
<code>k_rx_err_invalid_arg</code>	Bounds violation or unknown channel

Precondition

`riic_out` non-null

Since

Version 1.0.0

Here is the caller graph for this function:

8.105.4.33 internal`riic`write`phase()

```

rx_err_t internal_riic_write_phase (
    volatile rx_riic_regs_t * riic,
    const i2c_device_addr_t device_addr,
    const uint8_t * write_data,
    const uint16_t write_length) [static]

```

Execute I2C write phase for combined write-read transfer.

Performs the write portion of a write-read (register read) transaction. This typically writes a register address to the peripheral, which sets an internal pointer for the subsequent read phase.

8.105.4.34 Transaction Sequence

8.105.4.35 Error Handling

On any error (timeout or NACK), this function issues a STOP condition to release the bus before returning the error code.

Precondition

- riic points to valid, initialized RIIC channel
- device_addr.value <= 127
- write_data != nullptr
- write_length > 0
- Bus is idle (not busy)

Postcondition

- On success: Bus is active, internal address pointer set
- On failure: STOP issued, bus released

Note

- Does NOT issue STOP on success - caller must continue with read phase or issue STOP.
- On error, STOP is always issued for bus cleanup.

8.105.4.36 internal_send_start()

```
rx_err_t internal_send_start (
    volatile rx_riic_regs_t * riic) [static]
```

Generate I2C START condition on the bus.

Issues a START condition by setting the ST bit in ICCR2, then waits for hardware confirmation via the START flag in ICSR2. The START condition signals all peripherals that a transaction is beginning.

8.105.4.37 START Condition Timing

SDA ----+
 +-----
 SCL -----+
 +-----
 | |
 | |
 +- SCL goes low (start of first bit)
 +- SDA goes low while SCL high (START)

8.105.4.38 Hardware Sequence

1. Set ST bit in ICCR2 (request START)
2. Hardware pulls SDA low while SCL is high
3. Hardware sets START flag in ICSR2
4. Software clears START flag to acknowledge

Precondition

riic != nullptr
 Bus must be idle (BBSY = 0) - use [internal_wait_bus_ready\(\)](#) first
 RIIC channel must be enabled (ICE = 1)

Postcondition

START flag is cleared in ICSR2
 Bus is now busy (BBSY = 1)

Note

Clears the START detection flag after successful START.
 After START, caller must send address byte within timeout.

Warning

If START fails, caller must issue STOP to release bus.

Here is the caller graph for this function:

8.105.4.39 `internal_send_stop()`

```

rx_err_t internal_send_stop (
    volatile rx\_riic\_regs\_t * riic) [static]

```

Generate I2C STOP condition on the bus.

Issues a STOP condition by setting the SP bit in ICCR2, then waits for hardware confirmation via the STOP flag in ICSR2. The STOP condition releases the bus for other controllers.

8.105.4.40 STOP Condition Timing

```

SDA -----+-----
           |
SCL ----+---+-----
       |   |
       |   +- SDA goes high while SCL high (STOP)
       +- SCL goes high (end of last bit/ACK)

```

8.105.4.41 Hardware Sequence

1. Set SP bit in ICCR2 (request STOP)
2. Hardware drives SCL high
3. Hardware drives SDA high while SCL is high
4. Hardware sets STOP flag in ICSR2
5. Software clears STOP flag to acknowledge

8.105.4.42 Error Recovery

STOP is also used for error recovery - if a transaction fails at any point, issuing STOP releases the bus and resets the peripheral state machine.

Precondition

riic != nullptr
A transaction is in progress (bus is busy)

Postcondition

STOP flag is cleared in ICSR2
Bus is idle (BBSY = 0)
Peripheral state machine returns to idle

Note

Always call STOP at the end of a transaction or to recover from errors.
STOP after NACK in read transactions signals end of transfer to peripheral.

Best-Effort Cleanup

In error paths, STOP is called to release the bus even if the original error should be preserved. The calling function should:

```
if (err != k_rx_ok) {  
    rx_err_t stop_err = internal_send_stop(riic);  
    (void)stop_err; // Preserve original error  
    return err;  
}
```

8.105.4.44 `internal_write_address_for_read()`

```
rx_err_t internal_write_address_for_read (
    volatile rx_riic_regs_t * riic,
    const uint8_t addr_byte) [static]
```

Send the address|R byte that opens a controller-receive transaction.

After the controller switches to receive mode (ICCR2 = MST, TRS=0) and has issued START or repeated-START, the address byte with R bit must be sent. `internal_write_byte()` cannot be used here: per RX72N HW manual section 42.2.1 the TRS bit auto-clears to 0 on the rising edge of the 9th SCL of an addr|R byte, which moves the peripheral into receive mode and sets RDRF automatically – TEND and TDRE-reassertion no longer fire. Waiting for transmit-side flags in that state hangs forever; this helper waits for RDRF | NACKF instead.

Precondition

Bus is active; ICCR2 = MST (TRS=0); start condition already issued

Postcondition

On success: RDRF=1 in ICSR2, ICDRR holds the first data byte

Here is the caller graph for this function:

8.105.4.45 internal`write`byte()

```

rx_err_t internal_write_byte (
    volatile rx_riic_regs_t * riic,
    const uint8_t data) [static]
  
```

Transmit single byte over I2C bus.

Writes one byte to the I2C bus and waits for acknowledgment from the peripheral. This function handles both address bytes and data bytes.

8.105.4.46 Transmission Sequence

1. Wait for TDRE (Transmit Data Register Empty) flag
2. Write byte to ICDRT (Transmit Data Register)
3. Hardware shifts out 8 bits MSB-first
4. Hardware generates 9th clock for ACK
5. Peripheral drives SDA low (ACK) or leaves high (NACK)
6. Check NACKF flag to determine response

8.105.4.47 I2C Byte Timing

```

SCL  ++ ++ ++ ++ ++ ++ ++ ++ ++ ++
      || || || || || || || ||
      ++ ++ ++ ++ ++ ++ ++ ++ ++ ++
      D7 D6 D5 D4 D3 D2 D1 D0 ACK
SDA  -----+
      Data bits (8)      +- ACK (low)
  
```

8.105.4.48 NACK Handling

NACK is received when:

- Address byte: No peripheral at that address
- Data byte: Peripheral buffer full or error condition
- Last byte: Normal end-of-read signaling (expected)

Precondition

riic != nullptr (not checked - caller must ensure)
 START condition has been issued
 Previous byte (if any) has been acknowledged

Postcondition

On success, byte has been transmitted and ACK received
 On NACK, NACKF flag is cleared for next operation

Note

Does NOT send START or STOP - caller manages transaction framing.
 First byte after START should be address with R/W bit.

Warning

On NACK, caller should issue STOP to release bus.

Address Byte Format

For address bytes, caller must format as: $(\text{addr} \ll 1) \mid \text{direction}$

- Write: $(0x50 \ll 1) \mid 0 = 0xA0$
- Read: $(0x50 \ll 1) \mid 1 = 0xA1$

8.105.4.49 riic`deinit`peripheral()

```

rx_err_t riic_deinit_peripheral (
    const riic\_channel\_t channel) [nodiscard]

```

Deinitialize an RIIC channel that was initialized in peripheral mode.

Deinitialize an RIIC channel previously initialized in peripheral mode.

Disables the peripheral address match (ICSER.SAR0E), clears the SARL0/SARU0 address registers, resets the RIIC module, and marks the channel as uninitialized. After this call, [riic_init\(\)](#) or [riic_init_peripheral\(\)](#) may be called again on the same channel.

Precondition

channel.value must be in range [0, k_riic_max_channels - 1]

Channel must have been initialized via [riic_init_peripheral\(\)](#)

Postcondition

s_riic_channel_mode[channel.value] == k_riic_mode_uninitialized on success

RIIC peripheral address match disabled; hardware in reset state

Note

Only available on RX72N target (guarded by RX preprocessor)

Not thread-safe; provide external synchronization if needed

Here is the call graph for this function:

8.105.4.50 riic_init()

```

rx_err_t riic_init (
    riic_channel_t channel,
    uint32_t frequency_hz) [nodiscard]

```

Initialize RIIC channel for I2C controller communication.

Configures the specified RIIC peripheral channel for I2C controller mode at the requested clock frequency. Performs full hardware initialization including module stop release, pin function selection (SCL/SDA via MPC), internal reset sequence, bit rate register (BRH/BRL) calculation from PCLKB, and interrupt configuration.

8.105.4.51 Algorithm

1. Validate channel number (0-2) and frequency
2. Release RIIC module from module stop (MSTPCRB)
3. Assert internal reset (ICCR1.IICRST = 1)
4. Configure SCL/SDA pins via MPC register
5. Set bit rate registers (BRH/BRL) from PCLKB and frequency_hz
6. Configure noise filter, timeout detection
7. Release internal reset (ICCR1.IICRST = 0)
8. Enable I2C bus (ICCR1.ICE = 1)

8.105.4.52 Supported Frequencies

Frequency	Mode	BRL/BRH	Max Bus Length
100000 Hz	Standard	Auto-calculated	1 m
400000 Hz	Fast	Auto-calculated	0.3 m
1000000 Hz	Fast-plus	Auto-calculated	0.1 m

Parameters

in	channel	RIIC channel wrapper • channel.value range: 0-2 • Use {.value = N} designated initializer
in	frequency_hz	I2C clock frequency in Hz • Valid values: 100000, 400000, 1000000 • Must match connected device capabilities

Returns

rx_err_t Error code indicating success or failure

Return values

k_rx_ok	Channel successfully initialized
k_rx_err_invalid_arg	Channel > 2 or unsupported frequency
k_rx_err_invalid_state	Channel already initialized

Precondition

Channel must not be already initialized (call `riic_deinit` first to reinitialize)
 System clocks must be configured (PCLKB running at expected frequency)

Postcondition

RIIC channel configured and ready for I2C transactions
 SCL/SDA pins configured with open-drain output and internal pull-ups

Note

Thread Safety: NOT thread-safe. Initialize each channel from a single thread during system startup.

Example: Initialize IMU I2C Bus

```
riic_channel_t ch = {.value = 0};
rx_err_t err = riic_init(ch, 400000); // 400 kHz fast mode
if (err != k_rx_ok) {
    rx_log_error_val("I2C", "RIIC0 init failed", err);
    return;
}
rx_log_info("I2C", "RIIC0 initialized at 400 kHz");
```

Here is the call graph for this function:

8.105.4.53 riic`init`peripheral()

```

rx_err_t riic_init_peripheral (
    const riic_channel_t channel,
    const i2c_device_addr_t device_addr) [nodiscard]

```

Initialize RIIC channel in peripheral (device) mode.

Configures the RIIC peripheral to act as an I2C peripheral device, responding to a fixed 7-bit I2C address issued by a controller (RPI5). Sets up the peripheral address register (SARL0/SARU0), enables address match detection (ICSER.SAR0E), and leaves the module in peripheral mode (MS=0 in ICMR1).

8.105.4.54 Initialization Sequence

1. Validate channel number and device address
2. Enable RIIC module clock (clear MSTPCRB bit)
3. Reset RIIC internal state (IICRST)
4. Configure peripheral address in SARL0/SARU0
5. Enable SAR0 address match detection (ICSER.SAR0E)
6. Configure peripheral mode (MS=0), 7-bit addressing
7. Enable I2C bus interface (ICE)
8. Mark channel as initialized

Precondition

channel.value must be in range [0, k_riic_max_channels - 1]
 device_addr.value must be <= k_riic_addr_max_7bit (0x7F)

Postcondition

RIIC peripheral responds to device_addr on the I2C bus
 s_riic_channel_mode[channel.value] == k_riic_mode_peripheral

Note

Only available on RX72N target (guarded by RX preprocessor)
 Not thread-safe during initialization

Here is the call graph for this function:

8.105.4.55 riic`peripheral`read()

```

rx_err_t riic_peripheral_read (
    const riic\_channel\_t channel,

```

```
uint8_t * data,  
const uint16_t max_length,  
uint16_t * bytes_read) [nodiscard]
```

Read bytes written by the I2C controller to this peripheral.

Polls ICSR2.RDRF (Receive Data Register Full) to detect incoming bytes from the I2C controller (RPi5). Reads up to max_length bytes into the caller-supplied buffer. Returns immediately with bytes_read == 0 if no data is currently available (non-blocking). Each byte read clears the RDRF flag automatically on the RX72N.

8.105.4.56 Read Algorithm

1. Validate pointers, channel, and max_length
2. Clear *bytes_read to 0
3. Poll ICSR2.RDRF; if set, read ICDRR into data[*bytes_read], increment count
4. Repeat until RDRF clear or max_length reached
5. Return k_rx_ok with actual count in *bytes_read

Precondition

channel must be initialized via [riic_init_peripheral\(\)](#)
data != nullptr with at least max_length bytes of capacity
max_length >= 1 && max_length <= k_riic_peripheral_transfer_limit

Postcondition

*bytes_read contains the number of bytes placed in data (0 to max_length)
data[0..(*bytes_read)-1] contain valid received bytes on k_rx_ok

Note

Non-blocking: returns immediately with available data (bytes_read may be 0)
Only available on RX72N target (guarded by RX preprocessor)
Not thread-safe, caller must provide external synchronization

8.105.4.57 riic`peripheral`write()

```

rx_err_t riic_peripheral_write (
    const riic_channel_t channel,
    const uint8_t * data,
    const uint16_t length) [nodiscard]

```

Write bytes for the I2C controller to read from this peripheral.

Loads data bytes into the RIIC transmit data register (ICDRT) one at a time. For each byte, polls ICSR2.TDRE (Transmit Data Register Empty) until the register is available or a 1 ms timeout expires, then writes the byte. The controller clock-shifts bytes out automatically after each write.

8.105.4.58 Write Algorithm

1. Validate pointer, channel, and length
2. For each byte in data[0..length-1]: a. Poll ICSR2.TDRE with k_riic_periph_timeout_us count-down b. If timeout, return k_rx_err_timeout c. Write data[i] to ICDRT
3. Return k_rx_ok

Precondition

channel must be initialized via [riic_init_peripheral\(\)](#)
 data != nullptr with at least length valid bytes
 length >= 1

Postcondition

On k_rx_ok: all length bytes have been written to ICDRT
 On k_rx_err_timeout: partial write may have occurred (i bytes written)

Note

Only available on RX72N target (guarded by RX preprocessor)
 Not thread-safe, caller must provide external synchronization

Here is the call graph for this function:

8.105.4.59 riic_read()

```

rx_err_t riic_read (
    const riic_channel_t channel,
    const i2c_device_addr_t device_addr,
    uint8_t * data,
    const uint16_t length) [nodiscard]

```

Read data from an I2C peripheral device.

Read data from I2C device on specified RIIC channel.

Performs a complete I2C read transaction: START, address+R, receive data bytes (ACK all except last), NACK last byte, STOP. This function is suitable for reading device status, sensor data, or sequential memory reads where the device auto-increments its internal pointer.

8.105.4.60 Transaction Sequence

8.105.4.61 When to Use `riic_read()` vs `riic_write_read()`

Function	Use When
<code>riic_read()</code>	Device auto-increments address, or reading status
<code>riic_write_read()</code>	Need to specify register address first

8.105.4.62 Common Use Cases

- Read device status register (if device supports direct read)
- Continue reading after previous write set address pointer
- Read from devices with auto-increment address mode

Precondition

`riic_init()` called for this channel
`data != nullptr`
 Buffer size $\geq$ length
 length ≥ 1 && length ≤ 256
 device_addr.value ≤ 127

Postcondition

On success: data contains received bytes, bus released
 On failure: Bus released via STOP

Note

This is a blocking function - returns only after transfer complete.
 NACK is automatically sent before reading last byte.

Warning

Most peripherals require `riic_write_read()` to specify which register to read from. Use this function only when the device supports direct reads or address auto-increment.

Example: Read Temperature Sensor (Direct Read)

```

// Read 2 bytes from temperature sensor at address 0x48
// (sensor auto-reports temperature on read)
uint8_t temp_data[2];
riic_channel_t channel = {.value = 0};
i2c_device_addr_t addr = {.value = 0x48};

rx_err_t err = riic_read(channel, addr, temp_data, 2);
if (err == k_rx_ok) {
    int16_t raw = (temp_data[0] « 8) | temp_data[1];
    float celsius = raw * 0.0625f;
}

```

Here is the call graph for this function:

8.105.4.63 riic_write()

```

rx_err_t riic_write (
    const riic_channel_t channel,
    const i2c_device_addr_t device_addr,

```

```
const uint8_t * data,
const uint16_t length) [nodiscard]
```

Write data to an I2C peripheral device.

Write data to I2C device on specified RIIC channel.

Performs a complete I2C write transaction: START, address+W, data bytes, STOP. This function is suitable for writing configuration registers, sending commands, or storing data in EEPROM.

8.105.4.64 Transaction Sequence

8.105.4.65 Common Use Cases

Use Case	Data Format
Config register write	[reg_addr, value]
Multi-byte register	[reg_addr, val0, val1, ...]
EEPROM page write	[addr_hi, addr_lo, data...]
Sensor command	[command_↔ byte]

8.105.4.66 Error Handling

On any error (timeout or NACK), the function issues a STOP condition to release the bus before returning. The original error code is preserved.

Precondition

```
riic_init() called for this channel
data != nullptr
length >= 1 && length <= 256
device_addr.value <= 127
```

Postcondition

```
On success: All bytes transferred, bus released
On failure: Bus released via STOP
```

Note

This is a blocking function - returns only after transfer complete.
 STOP is always issued (success or failure) to release the bus.

Warning

NACK on address usually means device not present or wrong address.
 NACK on data may indicate device buffer full or write-protected.

Example: Write Configuration Register

```
// Write value 0x42 to register 0x05 of device at address 0x48
uint8_t config_data[2] = {0x05, 0x42}; // [reg_addr, value]
riic_channel_t channel = {.value = 0};
i2c_device_addr_t addr = {.value = 0x48};

rx_err_t err = riic_write(channel, addr, config_data, 2);
if (err != k_rx_ok) {
    handle_i2c_error(err);
}
```

Here is the call graph for this function:

8.105.4.67 riic`write`read()

```

rx_err_t riic_write_read (
    const riic\_channel\_t channel,

```

```

const i2c_device_addr_t device_addr,
const uint8_t * write_data,
const uint16_t write_length,
uint8_t * read_data,
const uint16_t read_length) [nodiscard]

```

Combined write-then-read I2C transaction (register read).

Write then read from I2C device using repeated START (combined transaction).

Performs a complete I2C write-read transaction using a repeated START condition. This is the most common pattern for reading registers from I2C peripherals: write the register address, then read the data.

8.105.4.68 Transaction Sequence (Register Read)

8.105.4.69 Why Repeated START?

The repeated START (Sr) is critical for atomic register access:

Approach	Bus Release	Risk
STOP + START	Yes	Another controller could interrupt
Repeated START	No	Transaction is atomic

Many I2C peripherals require repeated START and may not work correctly with separate write-then-read transactions.

8.105.4.70 Common Use Cases

Peripheral Type	write`data	read`length	Purpose
Temperature	[reg_↔ addr]	2	Read temp register
EEPROM	[addr_hi, addr_lo]	N	Read N bytes
Accelerometer	[reg_↔ addr]	6	Read XYZ axes

Peripheral Type	write`data	read`length	Purpose
RTC	[seconds_↔ reg]	7	Read time

Precondition

```

riic_init() called for this channel
write_data != nullptr
read_data != nullptr
write_length >= 1 && write_length <= 256
read_length >= 1 && read_length <= 256
device_addr.value <= 127

```

Postcondition

On success: read_data contains register contents, bus released
On failure: Bus released via STOP

Note

This is a blocking function - returns only after transfer complete.
Uses repeated START (no bus release between write and read phases).
NACK is automatically sent before reading last byte.

Example: Read WHO_AM_I Register from IMU

```

// Read WHO_AM_I register (0x0F) from MPU6050 at address 0x68
riic_channel_t channel = {.value = 0};
i2c_device_addr_t imu_addr = {.value = 0x68};

uint8_t reg_addr = 0x0F; // WHO_AM_I register
uint8_t who_am_i;

rx_err_t err = riic_write_read(channel, imu_addr,
                               &reg_addr, 1, // Write: register address
                               &who_am_i, 1); // Read: 1 byte

if (err == k_rx_ok && who_am_i == 0x68) {
    // IMU detected and responding correctly
}

```

Example: Read 6 Bytes of Accelerometer Data

```

// Read ACCEL_XOUT_H through ACCEL_ZOUT_L (6 bytes starting at 0x3B)
uint8_t reg_addr = 0x3B;
uint8_t accel_data[6];

rx_err_t err = riic_write_read(channel, imu_addr,
                               &reg_addr, 1,
                               accel_data, 6);

if (err == k_rx_ok) {
    int16_t accel_x = (accel_data[0] « 8) | accel_data[1];
    int16_t accel_y = (accel_data[2] « 8) | accel_data[3];
    int16_t accel_z = (accel_data[4] « 8) | accel_data[5];
}

```

8.105.5 Variable Documentation

8.105.5.1 k'riic'recovery'pins

const [riic_recovery_pins_t](#) k_riic_recovery_pins[k_riic_max_channels] [static]

Initial value:

```

= {
[k_riic_channel_0] = {0U, 0U, 0U, 0U, 0U},
[k_riic_channel_1] =
{0x0008C002U, k_riic_port2_odr0_addr, 1U, 0U, (uint8_t)((1U « 1) | (1U « 3))},
[k_riic_channel_2] = {0U, 0U, 0U, 0U, 0U},
}

```

Per-channel recovery pin lookup.

Mirrors hardware_init.c::internal_riic1_bus_recover for the RIIC1 channel; zero-filled entries are skipped. See STAR PCB schematic + docs/sections/03_hardware_pinout.tex for the canonical pin assignment.

Definition at line 620 of file [riic.c](#).

```

00620                                     {
00621 [k_riic_channel_0] = {0U, 0U, 0U, 0U, 0U},
00622 [k_riic_channel_1] =
00623 {0x0008C002U, k_riic_port2_odr0_addr, 1U, 0U, (uint8_t)((1U « 1) | (1U « 3))},
00624 [k_riic_channel_2] = {0U, 0U, 0U, 0U, 0U},
00625 };

```

Referenced by [internal_riic_bit_bang_handback\(\)](#), and [internal_riic_bit_bang_recover\(\)](#).

8.105.5.2 s'riic'channel'mode

`riic_channel_mode_t s_riic_channel_mode[k_riic_max_channels]` [static]

Initial value:

```
= {k_riic_mode_uninitialized,
   k_riic_mode_uninitialized,
   k_riic_mode_uninitialized}
```

Per-channel RIIC mode tracking array.

Tracks the operational mode of each RIIC channel: uninitialized, controller, or peripheral. Used to enforce that controller APIs are only called on controller-initialized channels and vice-versa.

Index	Channel	Initial State
0	RIIC0	k_riic_mode_uninitialized
1	RIIC1	k_riic_mode_uninitialized
2	RIIC2	k_riic_mode_uninitialized

Invariant

Array size == k_riic_max_channels (3)

Warning

Do not modify directly – only `riic_init()`, `riic_init_peripheral()`, and `riic_deinit_peripheral()` may write to this array.

Note

Not thread-safe; provide external synchronization if needed.

Since

Version 1.0.0

Definition at line 900 of file `riic.c`.

```
00900                                     {k_riic_mode_uninitialized,
00901                                     k_riic_mode_uninitialized,
00902                                     k_riic_mode_uninitialized};
```

Referenced by `riic_deinit_peripheral()`, `riic_init()`, `riic_init_peripheral()`, `riic_peripheral_read()`, `riic_peripheral_write()`, `riic_read()`, `riic_write()`, and `riic_write_read()`.

8.105.5.3 s'tag

`const char* const s_tag = "RIIC"` [static]

Logging tag for RIIC driver messages.

Used with `rx_log_error()` and `rx_log_debug()` for consistent log output formatting. All RIIC driver log messages are prefixed with "RIIC".

Note

Not thread-safe, but read-only after initialization.

Definition at line 570 of file `riic.c`.

00046  * ## I2C Protocol Implementation
00047  *
00048  * This driver implements the I2C protocol in controller mode:
00049  *
00050  * ### Write Transaction
00051  *
00052  * Controller                                     Peripheral
00053  * |----- START ----->|
00054  * |----- Address + W (0) ----->|
00055  * |<--- ACK -----<|
00056  * |----- Data Byte 0 ----->|
00057  * |<--- ACK -----<|
00058  * |----- Data Byte N ----->|
00059  * |<--- ACK -----<|
00060  * |----- STOP ----->|
00061  *
00062  *
00063  *
00064  * ### Read Transaction
00065  *
00066  * Controller                                     Peripheral
00067  * |----- START ----->|
00068  * |----- Address + R (1) ----->|
00069  * |<--- ACK -----<|
00070  * |<--- Data Byte 0 -----<|
00071  * |----- ACK ----->|
00072  * |<--- Data Byte N -----<|
00073  * |----- NACK (last byte) ----->|
00074  * |----- STOP ----->|
00075  *
00076  *
00077  *
00078  * ### Write-Read Transaction (Register Read)
00079  *
00080  * Controller                                     Peripheral
00081  * |----- START ----->|
00082  *

```

```

00083 * |---- Address + W (0) ----->|
00084 * |<--- ACK -----<-|
00085 * |---- Register Address ----->|
00086 * |<--- ACK -----<-|
00087 * |---- REPEATED START ----->|
00088 * |---- Address + R (1) ----->|
00089 * |<--- ACK -----<-|
00090 * |<--- Data Byte 0 -----<-|
00091 * |---- NACK ----->|
00092 * |---- STOP ----->|
00093 * ```
00094 *
00095 * ## Bit Rate Calculation
00096 *
00097 * The I2C clock frequency is calculated from PCLKB (60 MHz) as:
00098 *
00099 * @f[
00100 * f_{SCL} = \frac{f_{PCLKB}}{(ICBRL + ICBRH + 2) \times 2^{CKS}}
00101 * @f]
00102 *
00103 * For simplified calculation with 50% duty cycle (ICBRL = ICBRH):
00104 *
00105 * @f[
00106 * \text{divisor} = \frac{f_{PCLKB}}{f_{SCL} \times 3}
00107 * @f]
00108 *
00109 * | Mode | Speed | Divisor | Actual Rate |
00110 * |-----|-----|-----|-----|
00111 * | Standard | 100 kHz | 200 | 100.0 kHz |
00112 * | Fast | 400 kHz | 50 | 400.0 kHz |
00113 * | Fast Plus | 1 MHz | 20 | 1.00 MHz |
00114 *
00115 * ## Memory Map (Chapter 42 - RIIC)
00116 *
00117 * | Channel | Base Address | Pin SCL | Pin SDA | Module Stop Bit |
00118 * |-----|-----|-----|-----|-----|
00119 * | RIIC0 | 0x00088300 | P16 | P17 | MSTPB21 (MSTPCRB b21) |
00120 * | RIIC1 | 0x00088320 | P21 | P20 | MSTPB20 (MSTPCRB b20) |
00121 * | RIIC2 | 0x00088340 | P66 | P67 | MSTPC17 (MSTPCRC b17) |
00122 *
00123 * ## Register Offsets (per channel)
00124 *
00125 * | Offset | Register | Description |
00126 * |-----|-----|-----|
00127 * | 0x00 | ICCR1 | Control Register 1 |
00128 * | 0x01 | ICCR2 | Control Register 2 |
00129 * | 0x02 | ICMR1 | Mode Register 1 |
00130 * | 0x03 | ICMR2 | Mode Register 2 |
00131 * | 0x04 | ICMR3 | Mode Register 3 |
00132 * | 0x10 | ICBRL | Bit Rate Low period |
00133 * | 0x11 | ICBRH | Bit Rate High period |
00134 * | 0x12 | ICDRT | Transmit Data Register |
00135 * | 0x13 | ICDRR | Receive Data Register |
00136 *
00137 * ## Error Handling
00138 *
00139 * The driver provides comprehensive error detection:
00140 * - **k_rx_err_null_ptr**: nullptr passed to function
00141 * - **k_rx_err_invalid_arg**: Invalid channel, address, or frequency
00142 * - **k_rx_err_invalid_state**: Channel not initialized
00143 * - **k_rx_err_timeout**: Bus busy or operation timeout
00144 * - **k_rx_err_nack**: Peripheral did not acknowledge
00145 *
00146 * ## NASA Power of 10 Compliance
00147 *
00148 * | Rule | Implementation |
00149 * |-----|-----|
00150 * | Rule 1 | No goto, setjmp, or recursion - sequential error handling |
00151 * | Rule 2 | Bounded loops - all loops use k_riic_timeout_us timeout |
00152 * | Rule 3 | No dynamic memory - static channel state array |
00153 * | Rule 4 | Short functions - each < 60 lines |
00154 * | Rule 5 | Validation - RX_CHECK_NULL_PTR, RX_CHECK_RANGE_TAG |
00155 * | Rule 6 | Smallest scope - local variables declared at point of use |
00156 * | Rule 7 | All return values checked - RX_RETURN_ON_ERROR |
00157 * | Rule 8 | Limited preprocessor - only RX_CHECK macros |
00158 * | Rule 9 | Function pointers via interface pattern (not used here) |
00159 * | Rule 10 | Compiles with -Wall -Wextra -Werror |
00160 *
00161 * ## SOLID Principles Compliance
00162 *
00163 * | Principle | Implementation |
00164 * |-----|-----|
00165 * | **S** Single Responsibility | Driver handles only RIIC I2C operations |
00166 * | **O** Open/Closed | Supports multiple frequencies via parameter |
00167 * | **L** Liskov Substitution | Consistent error codes across all functions |
00168 * | **I** Interface Segregation | Separate read/write/write-read APIs |
00169 * | **D** Dependency Inversion | Uses hardware.h abstraction for registers |

```

```

00170 *
00171 * @par Thread Safety
00172 * This module is NOT thread-safe. Each RIIC channel should be accessed
00173 * by only one thread at a time. If multiple threads need I2C access, provide
00174 * external synchronization (mutex/semaphore) at the application level.
00175 *
00176 * @par Example: Read Temperature Sensor
00177 * @code
00178 * // Initialize RIIC0 at 400 kHz (Fast mode)
00179 * riic_channel_t channel = {.value = 0};
00180 * rx_err_t err = riic_init(channel, 400000);
00181 * if (err != k_rx_ok) {
00182 *     handle_error(err);
00183 *     return;
00184 * }
00185 *
00186 * // Read 2 bytes from temperature sensor at address 0x48
00187 * i2c_device_addr_t sensor_addr = {.value = 0x48};
00188 * uint8_t temp_reg = 0x00; // Temperature register
00189 * uint8_t temp_data[2];
00190 *
00191 * err = riic_write_read(channel, sensor_addr, &temp_reg, 1, temp_data, 2);
00192 * if (err == k_rx_ok) {
00193 *     int16_t raw_temp = (temp_data[0] << 8) | temp_data[1];
00194 *     float celsius = raw_temp * 0.0625f; // LM75 resolution
00195 * }
00196 * @endcode
00197 *
00198 * @see rx72n_riic_regs.h RIIC register definitions
00199 * @see hardware.h Hardware abstraction layer

=====
00218 * Constants
00219 *
=====
00220 * All constants use C23 typed enums per STAR coding standards.
00221 * No magic numbers - every value has a named constant with documentation.
00222 *
=====
00223 */
00224 /**
00225 * @enum riic_constants_t
00226 * @brief RIIC channel count, timeout, and transfer limit constants
00227 *
00228 * @details
00229 * General-purpose constants for RIIC driver operation including channel
00230 * limits, timeout values, and transfer size constraints.
00231 *
00232 * @par Timeout Selection
00233 * The 10ms timeout provides sufficient margin for:
00234 * - Standard mode: 100 kHz = 10us/bit, 90us/byte -> 10ms = ~111 bytes
00235 * - Fast mode: 400 kHz = 2.5us/bit, 22.5us/byte -> 10ms = ~444 bytes
00236 * - Fast Plus: 1 MHz = 1us/bit, 9us/byte -> 10ms = ~1111 bytes
00237 *
00238 * @invariant k_riic_max_channels == 3 (hardware limitation)
00239 * @invariant k_riic_max_transfer_length == 256 (single-byte length limit)
00240 */
00241
00242 typedef enum : uint32_t {
00243     k_riic_max_channels = 3, /**< Total RIIC channels: RIIC0, RIIC1, RIIC2 */
00244     k_riic_timeout_us = 25000, /**< Busy-loop iteration budget for I2C flag waits.
00245     * Each iteration reads ICSR2/ICCR2 + decrements a
00246     * volatile counter (~10 cycles @ 240 MHz ~ 40 ns),
00247     * so 25k iters ~ 1 ms wall time -- enough to
00248     * cover a byte at 100 kHz (90 us) with 10x slack
00249     * for clock stretching. Kept below the 900 ms IWDWT
00250     * window even if a 256-byte transfer stacks up
00251     * 256 per-byte timeouts back-to-back. */
