00450
00451 /**
00452 * @enum riic_icmr3_bits_t
00453 * @brief ICMR3 (Mode Register 3) ACK/NACK control bit definitions
00454 *
00455 * @details
00456 * ICMR3 controls ACK/NACK transmission during receive operations. The key
00457 * field is ACKBT (Acknowledge Bit), which determines whether the controller
00458 * sends an ACK or NACK after each received byte.
00459 *
00460 * ## ACK/NACK Signalling Rules (I2C Specification)
00461 *
00462 * - Set ACKBT=0 (clear bit) to send ACK: instructs the peripheral to continue
00463 * transmitting; used for all bytes except the last in a read transfer.
00464 * - Set ACKBT=1 (set bit) to send NACK: instructs the peripheral to stop
00465 * transmitting; must be applied before clocking in the final byte so that
00466 * the NACK is sent automatically at the correct clock edge.
00467 *
00468 * ## ICMR3 Register Bit Layout (relevant bits)
00469 *
00470 * | Bit | Name | Function |
00471 * |-----|-----|-----|
00472 * | 4 | ACKWP | ACKBT write protect (1=writeable) |
00473 * | 3 | ACKBT | ACK/NACK bit to transmit |
00474 *
00475 * @invariant k_riic_icmr3_ackbt_pos == 3 matches the RX72N hardware bit
00476 * position for ACKBT in ICMR3; changing this breaks ACK/NACK control
00477 * @invariant k_riic_icmr3_ackbt_mask == (1U < 3) == 0x08; derived from pos
00478 * @invariant k_riic_icmr3_ackwp_pos == 4 matches the RX72N hardware bit
00479 * position for ACKWP; changing this silently breaks ACKBT writes
00480 * @invariant k_riic_icmr3_ackwp_mask == (1U < 4) == 0x10; derived from pos
00481 *
00482 * @note NACK must be sent before reading the last byte to signal to the
00483 * peripheral that the transfer is complete per I2C specification.
00484 *
00485 * @note ACKWP=1 is REQUIRED before any ACKBT write. Without it, writes to
00486 * ACKBT are silently ignored -- the controller keeps ACKing every byte,
00487 * the peripheral never sees NACK, and STOP times out with the bus
00488 * locked. ACKWP=1 is set in riic_init() as part of k_riic_icmr3_init.
00489 *
00490 * @code
00491 * // Prepare to NACK the last byte in a read transfer (ACKWP must already be 1)
00492 * volatile rx_riic_regs_t* riic = internal_get_riic_base(k_riic_channel_0);
00493 * riic->icmr3 |= k_riic_icmr3_ackbt_mask; // Set ACKBT=1 -> send NACK
00494 *
00495 * // Re-enable ACK for subsequent transfers
00496 * riic->icmr3 &= (uint8_t)~k_riic_icmr3_ackbt_mask; // Set ACKBT=0 -> send ACK
00497 * @endcode
00498 *
00499 * @see internal_read_byte() Uses these constants to control ACK/NACK output
00500 * @see riic_read() Orchestrates NACK signalling for multi-byte reads
00501 *
00502 * @since Version 1.0.0

00667 * @brief Bit-bang 9 SCL edges + manual STOP to recover an externally-stuck bus
00668 *
00669 * @details
00670 * Called from internal_wait_bus_ready when BBSY stays latched even after
00671 * an IICRST pulse. That combination means an I2C peripheral on the bus
00672 * (BNO055 or BMP280 in the STAR system) got interrupted mid-byte -- e.g.
00673 * the RX72N reset during a previous transaction -- and is still holding
00674 * SDA low waiting to finish sending the remaining bits of its byte + ACK.
00675 * IICRST only resets the RIIC controller side; it does not toggle SCL on
00676 * the wire, so it cannot unstick an external peripheral. The only
00677 * software path that clears this is to physically wiggle SCL from the
00678 * MCU pad -- which requires handing the pad from RIIC back to GPIO long
00679 * enough to clock out a full byte + ACK + STOP.
00680 */

```

```

00684 * Sequence:
00685 * 1. Drop PMR -> pads are GPIO again, RIIC loses them.
00686 * 2. Enable N-ch open-drain so we cannot drive-fight a peripheral still
00687 * holding the line low.
00688 * 3. Drive both lines high, set as output. External pull-ups dominate.
00689 * 4. 9x { SCL low; wait; SCL high; wait } -- one byte + ACK worth of
00690 * clocks, enough to clock out any peripheral stuck mid-byte.
00691 * 5. Manual STOP: SDA low -> high with SCL high -- tells any peripheral
00692 * still listening "transaction over, idle the bus".
00693 * 6. Tristate pads, clear open-drain. Leave PMR=0. The caller raises
00694 * PMR back to 1 AFTER it has reset the RIIC peripheral (IICRST +
00695 * SOWP dance), so the peripheral hands the pads back already in a
00696 * "driving high" state. Raising PMR while the peripheral still has
00697 * leftover SCLO=SDAO=0 from the previous transaction would glitch
00698 * the bus low again immediately.
00699 *
00700 * Only RIIC channels with a populated entry in k_riic_recovery_pins[]
00701 * are handled; other channels return silently.
00702 *
00703 *
00704 * @pre MPC PFS values for SCL/SDA were set during channel init and have
00705 * not been disturbed (we only toggle PMR, not PFS).
00706 * @post PMR for SCL/SDA is CLEARED (pads stay in GPIO mode, tristated).
00707 * Caller must reset the RIIC peripheral and then raise PMR.
00708 * @post PDR bits for SCL/SDA are cleared (tristated).

00779 /**
00780 * @brief Pulse IICRST on a controller-initialized RIIC channel and restore config.
00781 *
00782 * @details
00783 * Per RX72N HW manual section 42.2.1, writing 1 to ICCR1.IICRST while
00784 * ICCR1.ICE=0 performs an internal reset of the RIIC peripheral's FSM
00785 * without touching the pin mux. That drops any half-completed transaction
00786 * state -- BBSY, MST, TRS, pending SP/RS/ST request bits, NACKF, latched
00787 * AL, the "dummy read kicked reception" flag -- back to idle, which is
00788 * what we need before a new transaction when an earlier transaction on
00789 * the same peripheral may have left the FSM partially advanced. The
00790 * config registers (ICBRH/L, ICMR1..3) are wiped by IICRST, so we
00791 * restore them from the live values (which were set in riic_init() and
00792 * must already be valid since ICE was on before the pulse).
00793 *
00794 * Do NOT substitute this for riic_init(): this helper assumes MSTPCR and
00795 * MPC/PFS are already set up and that ICE=1 was previously toggled to
00796 * latch the peripheral out of module-stop. It is a fast pre-transaction
00797 * FSM scrub, not a cold boot.
00798 *
00799 * Currently unused in the main transaction path -- kept as a [[maybe_unused]]
00800 * helper because it is the right escape hatch when the FSM has been
00801 * observed to get stuck mid-transaction and the bit-bang recovery in
00802 * internal_wait_bus_ready() is too heavyweight (it tears down and rebuilds
00803 * pad direction via PMR, which adds ~100 us versus ~2 us here).
00804 *
00805 *
00806 * @pre ICE was set to 1 earlier (channel previously passed riic_init).
00807 * @post ICCR1.ICE = 1, ICCR1.IICRST = 0, ICMR1..3 / ICBRH/L restored,
00808 *       ICSR1 / ICSR2 cleared.

00912 /**
00913 * @brief Get RIIC channel register base address from channel number
00914 *
00915 * @details
00916 * Maps an RIIC channel number (0-2) to its corresponding hardware register
00917 * base address using a compile-time-dispatched switch statement. This function
00918 * is the single point of truth for the channel-to-address mapping and provides
00919 * a clean abstraction between the logical channel index used throughout the
00920 * driver and the physical memory-mapped peripheral addresses defined by the
00921 * RX72N hardware.
00922 *
00923 * ## Channel-to-Address Mapping
00924 *
00925 * The three RIIC channels are located at fixed, evenly spaced addresses in the
00926 * RX72N peripheral address space (0x00088300, 0x00088320, 0x00088340). Each
00927 * block is 32 bytes in size and contains all control, status, bit-rate, and
00928 * data registers for one channel.
00929 *
00930 * ## Memory Map
00931 *
00932 * | Channel | Accessor | Base Address | Register Block Size |
00933 * |-----|-----|-----|-----|
00934 * | 0       | riic0()  | 0x00088300   | 32 bytes |
00935 * | 1       | riic1()  | 0x00088320   | 32 bytes |
00936 * | 2       | riic2()  | 0x00088340   | 32 bytes |
00937 *
00938 * ## Why Return NULL for Invalid Channel
00939 *
00940 * Returning nullptr for an out-of-range channel allows every caller to perform
00941 * a single null-pointer check with RX_CHECK_NULL_PTR rather than duplicating

```

```

00942 * range validation logic. This pattern is consistent with rx_port_get_base()
00943 * in the GPIO driver.
00944 *
00945 *
00946 *
00947 * @pre channel must be less than k_riic_max_channels (3); values >= 3 yield nullptr
00948 * @pre caller must have verified that the corresponding RIIC module stop bit in
00949 * MSTPCR_B has been cleared (module enabled) before using the returned pointer
00950 * @post returned pointer is non-NULL if and only if channel is 0, 1, or 2
00951 * @post returned pointer, when non-NULL, is aligned to the RIIC peripheral register
00952 * block boundary as required by the RX72N hardware specification
00953 *
00954 * @note This function does NOT validate the channel - the caller is responsible
00955 * for ensuring the value is in range before calling
00956 * @note The return type is volatile to prevent the compiler from optimizing away
00957 * hardware register reads or writes through the returned pointer
00958 *
00959 * @par Performance:
00960 * O(1) - simple switch statement with a direct return per case
00961 *
00962 * @par Example:
00963 * @code
00964 * // Look up the register base for RIIC channel 1 and send a START condition
00965 * volatile rx_riic_regs_t* riic = internal_get_riic_base(k_riic_channel_1);
00966 * if (riic == nullptr) {
00967 *     return k_rx_err_invalid_arg;
00968 * }
00969 * riic->iccr2 |= k_riic_iccr2_st; // Issue START condition
00970 * @endcode
00971 *
00972 * @see riic0() Inline accessor for RIIC channel 0 base address
00973 * @see riic1() Inline accessor for RIIC channel 1 base address
00974 * @see riic2() Inline accessor for RIIC channel 2 base address
00975 * @see k_riic_max_channels Upper bound on valid channel numbers
00976 *
00977 * @since Version 1.0.0

00998 * @brief Calculate RIIC bit rate register values for target frequency
00999 *
01000 * @details
01001 * Computes the ICBRL and ICBRH register values to achieve the desired I2C
01002 * bus frequency. Uses a simplified calculation assuming 50% duty cycle
01003 * (equal high and low periods).
01004 *
01005 * ### Calculation Algorithm
01006 *
01007 * The RX72N RIIC bit rate formula (from Chapter 42):
01008 * @f[
01009 * f_{SCL} = \frac{f_{PCLKB}}{(ICBRL + 1) + (ICBRH + 1) + \text{sync}}
01010 * @f]
01011 *
01012 * Simplified for 50% duty cycle (ICBRL = ICBRH):
01013 * @f[
01014 * \text{divisor} = \frac{f_{PCLKB}}{f_{target}} \times 3
01015 * @f]
01016 *
01017 * ### Example Calculations (PCLKB = 60 MHz)
01018 *
01019 * | Target | Calculation | Divisor | Actual Rate |
01020 * |-----|-----|-----|-----|
01021 * | 100 kHz | 60M / (100k x 3) | 200 | 100.0 kHz |
01022 * | 400 kHz | 60M / (400k x 3) | 50 | 400.0 kHz |
01023 * | 1 MHz | 60M / (1M x 3) | 20 | 1.00 MHz |
01024 *
01025 *
01026 *
01027 * @pre icbri != nullptr
01028 * @pre icbrh != nullptr

```

```

01029 * @pre frequency_hz is a supported I2C frequency
01030 * @post *icbri contains the low-period divisor (1-255)
01031 * @post *icbrh contains the high-period divisor (1-255)
01032 * @post *icbri == *icbrh (50% duty cycle)
01033 *
01034 * @note Uses PCLKB (60 MHz) as the source clock per RX72N specification.
01035 * @note For asymmetric duty cycle, manually set ICBRL != ICBRH after init.
01036 *
01037 * @warning Frequencies outside 100 kHz - 1 MHz may produce out-of-range divisors.
01038 *
01039 * @see riic_init() Uses this function during channel initialization

01080 * @brief Wait for I2C bus to become idle (not busy)
01081 *
01082 * @details
01083 * Polls the BBSY (Bus Busy) bit in ICCR2 until the bus is free or timeout
01084 * occurs. This function must be called before starting a new I2C transaction
01085 * to ensure no other controller is using the bus (multi-controller arbitration).
01086 *
01087 * ## Bus Busy Detection
01088 *
01089 * The BBSY bit is set when:
01090 * - A START condition is detected on the bus
01091 * - The controller has issued a START condition
01092 *
01093 * The BBSY bit is cleared when:
01094 * - A STOP condition is detected on the bus
01095 * - Bus arbitration is lost
01096 *
01097 * ## Timeout Calculation
01098 *
01099 * At 100 kHz (slowest mode), maximum byte transfer time:
01100 * - 9 bits per byte (8 data + 1 ACK) x 10 us = 90 us
01101 * - For 256 bytes (max transfer): 256 x 90 us = 23 ms
01102 *
01103 * The 10 ms timeout (k_riic_timeout_us) provides margin for typical
01104 * operations while catching true bus-stuck conditions.
01105 *
01106 *
01107 *
01108 * @pre riic != nullptr
01109 * @pre RIIC channel must be initialized and enabled
01110 * @post Bus is idle if k_rx_ok returned
01111 *
01112 * @note This is a blocking function - polls in tight loop.
01113 * @note Timeout is ~10ms at k_riic_timeout_us iterations.
01114 *
01115 * @warning In multi-controller systems, bus may become busy again immediately

```

```

01116 *      after this function returns - caller should proceed quickly.

01413  * @brief Generate I2C STOP condition on the bus
01414  *
01415  * @details
01416  * Issues a STOP condition by setting the SP bit in ICCR2, then waits for
01417  * hardware confirmation via the STOP flag in ICSR2. The STOP condition
01418  * releases the bus for other controllers.
01419  *
01420  * ## STOP Condition Timing
01421  *
01422  * ```
01423  * SDA -----+-----
01424  *             |
01425  * SCL ---+-----+-----
01426  *       |   |
01427  *       |   +- SDA goes high while SCL high (STOP)
01428  *       +- SCL goes high (end of last bit/ACK)
01429  * ```
01430  *
01431  * ## Hardware Sequence
01432  *
01433  * 1. Set SP bit in ICCR2 (request STOP)
01434  * 2. Hardware drives SCL high
01435  * 3. Hardware drives SDA high while SCL is high
01436  * 4. Hardware sets STOP flag in ICSR2
01437  * 5. Software clears STOP flag to acknowledge
01438  *
01439  * ## Error Recovery
01440  *
01441  * STOP is also used for error recovery - if a transaction fails at any
01442  * point, issuing STOP releases the bus and resets the peripheral state
01443  * machine.
01444  *
01445  *
01446  *
01447  *
01448  * @pre riic != nullptr
01449  * @pre A transaction is in progress (bus is busy)
01450  * @post STOP flag is cleared in ICSR2
01451  * @post Bus is idle (BBSY = 0)
01452  * @post Peripheral state machine returns to idle
01453  *
01454  * @note Always call STOP at the end of a transaction or to recover from errors.
01455  * @note STOP after NACK in read transactions signals end of transfer to peripheral.
01456  *
01457  * @par Best-Effort Cleanup
01458  * In error paths, STOP is called to release the bus even if the original
01459  * error should be preserved. The calling function should:
01460  *
01461  * @code
01461  * if (err != k_rx_ok) {
01462  *     rx_err_t stop_err = internal_send_stop(riic);
01463  *     (void)stop_err; // Preserve original error

```

```

01464 *   return err;
01465 * }
01466 * @endcode
01467 *
01468 * @see internal_send_start() Companion function for starting transactions
01469 */
01470 static rx_err_t internal_send_stop(volatile rx_riic_regs_t* riic)
01471 {
01472     RX_CHECK_NULL_PTR(riic, s_tag, "RIIC peripheral base is nullptr");
01473     /* Issue stop condition */
01474     riic->iccr2 |= k_riic_iccr2_sp;
01475     /* Wait for stop condition to be issued */
01476     uint32_t timeout = k_riic_timeout_us;

01486     return k_rx_ok;
01487 }
01488 /**
01489 * @brief Transmit single byte over I2C bus
01490 *
01491 * @details
01492 * Writes one byte to the I2C bus and waits for acknowledgment from the
01493 * peripheral. This function handles both address bytes and data bytes.
01494 *
01495 * ## Transmission Sequence
01496 *
01497 * 1. Wait for TDRE (Transmit Data Register Empty) flag
01498 * 2. Write byte to ICDRT (Transmit Data Register)
01499 * 3. Hardware shifts out 8 bits MSB-first
01500 * 4. Hardware generates 9th clock for ACK
01501 * 5. Peripheral drives SDA low (ACK) or leaves high (NACK)
01502 * 6. Check NACKF flag to determine response
01503 *
01504 * ## I2C Byte Timing
01505 *
01506 * ```
01507 * SCL  ++ ++ ++ ++ ++ ++ ++ ++ ++ ++
01508 *      || || || || || || || ||
01509 *      ++ ++ ++ ++ ++ ++ ++ ++ ++
01510 *      D7 D6 D5 D4 D3 D2 D1 D0 ACK
01511 * SDA  -----+
01512 *      Data bits (8)      +- ACK (low)
01513 * ```
01514 *
01515 * ## NACK Handling
01516 *
01517 * NACK is received when:
01518 * - Address byte: No peripheral at that address
01519 * - Data byte: Peripheral buffer full or error condition
01520 * - Last byte: Normal end-of-read signaling (expected)
01521 *
01522 * @pre riic != nullptr (not checked - caller must ensure)
01523 * @pre START condition has been issued
01524 * @pre Previous byte (if any) has been acknowledged
01525 * @post On success, byte has been transmitted and ACK received
01526 * @post On NACK, NACKF flag is cleared for next operation
01527 *
01528 * @note Does NOT send START or STOP - caller manages transaction framing.
01529 * @note First byte after START should be address with R/W bit.
01530 *
01531 * @warning On NACK, caller should issue STOP to release bus.
01532 *
01533 * @par Address Byte Format
01534 * For address bytes, caller must format as: (addr « 1) | direction
01535 * - Write: (0x50 « 1) | 0 = 0xA0
01536 * - Read: (0x50 « 1) | 1 = 0xA1
01537 *
01538 * @see internal_read_byte() Companion function for receiving bytes
01539 */

01866  * @brief Execute I2C read phase for combined write-read transfer
01867  *
01868  * @details
01869  * Performs the read portion of a write-read (register read) transaction.
01870  * Issues a repeated START condition (without releasing the bus), then
01871  * reads data bytes from the peripheral.
01872  *
01873  * ## Transaction Sequence
01874  *
01875  * ```
01876  * Controller                                Peripheral
01877  * |                                           |
01878  * | (Write phase completed, no STOP)         |
01879  * |                                           |
01880  * |---- REPEATED START ----->|
01881  * |---- Address + R (1) ----->|
01882  * |<--- ACK -----<|
01883  * |<--- Data Byte 0 -----<|
01884  * |---- ACK ----->|
01885  * |<--- Data Byte N-1 -----<|
01886  * |---- NACK ----->| <- Signals end
01887  * |                                           |
01888  * | (Caller issues STOP)                   |
01889  * ```
01890  *
01891  * ## Repeated START vs STOP+START
01892  *
01893  * The repeated START (Sr) is critical for atomic register reads:
01894  * - Prevents other controllers from arbitrating between write and data read
01895  * - Ensures peripheral's internal address pointer is still valid
01896  * - Required by many I2C peripherals (EEPROMs, sensors, etc.)
01897  *
01898  * ## ACK/NACK Protocol

```

```

01899 *
01900 * Per I2C specification, the controller must NACK the last byte to signal
01901 * end of read. This allows the peripheral to release SDA for the STOP
01902 * condition.
01903 *
01904 *
01905 *
01906 * @pre riic points to valid, initialized RIIC channel
01907 * @pre Write phase has been completed (bus is active)
01908 * @pre device_addr.value <= 127
01909 * @pre read_data != nullptr
01910 * @pre read_length > 0
01911 * @post On success: read_data contains received bytes
01912 * @post On failure: STOP issued, bus released
01913 *
01914 * @note Does NOT issue STOP on success - caller must issue STOP.
01915 * @note On error, STOP is always issued for bus cleanup.
01916 * @note NACK is automatically sent on last byte.
01917 *
01918 * @see internal_riic_write_phase() Precedes this function in write-read
01919 * @see riic_write_read() Public API that combines both phases

02055 * @brief Initialize RIIC (I2C) channel for controller mode operation
02056 *
02057 * @details
02058 * Configures an RIIC channel for I2C controller mode communication at the
02059 * specified bus frequency. This function must be called before any I2C
02060 * transfers on the channel.
02061 *
02062 * ## Initialization Sequence
02063 *
02064 * 1. Validate channel number and frequency
02065 * 2. Enable RIIC module clock (clear MSTPCRB bit)
02066 * 3. Reset RIIC internal state (ICRST)
02067 * 4. Calculate and configure bit rate registers
02068 * 5. Configure controller mode, 7-bit addressing
02069 * 6. Enable I2C bus interface (ICE)

```

```

02070 * 7. Mark channel as initialized
02071 *
02072 * ## Module Stop Control
02073 *
02074 * The RIIC peripheral is disabled by default to save power. This function
02075 * enables the module clock by clearing the appropriate MSTPCRB bit:
02076 *
02077 * | Channel | MSTPCRB Bit | Default State |
02078 * |-----|-----|-----|
02079 * | RIIC0 | Bit 21 | Stopped |
02080 * | RIIC1 | Bit 20 | Stopped |
02081 * | RIIC2 | Bit 19 | Stopped |
02082 *
02083 * ## Supported Frequencies
02084 *
02085 * | Frequency | Mode | Use Case |
02086 * |-----|-----|-----|
02087 * | 100 kHz | Standard | Legacy devices |
02088 * | 400 kHz | Fast | Most I2C peripherals |
02089 * | 1 MHz | Fast Plus | High-speed sensors |
02090 *
02091 *
02092 *
02093 * @pre channel.value < 3
02094 * @pre frequency_hz is one of: 100000, 400000, 1000000
02095 * @post Channel is enabled and ready for I2C transfers
02096 * @post s_riic_channel_mode[channel.value] == k_riic_mode_controller
02097 *
02098 * @note This function modifies protected registers (MSTPCRB) using PRCR unlock.
02099 * @note Re-initializing an already initialized channel is allowed.
02100 * @note Pin configuration (MPC) must be done separately if needed.
02101 *
02102 * @warning Using unsupported frequencies may cause communication failures.
02103 *
02104 * @par Example
02105 * @code
02106 * // Initialize RIIC0 for Fast mode (400 kHz)
02107 * riic_channel_t channel = {.value = 0};
02108 * rx_err_t err = riic_init(channel, 400000);
02109 * if (err != k_rx_ok) {
02110 *     rx_log_error("I2C", "Failed to initialize RIIC0");
02111 * }
02112 * @endcode

02279 * @brief Write data to an I2C peripheral device
02280 *
02281 * @details
02282 * Performs a complete I2C write transaction: START, address+W, data bytes,
02283 * STOP. This function is suitable for writing configuration registers,
02284 * sending commands, or storing data in EEPROM.
02285 *
02286 * ## Transaction Sequence
02287 *
02288 * ```
02289 * Controller                                Peripheral
02290 * |----- START ----->|
02291 * |----- Address + W (0) ----->|
02292 * |<--- ACK -----<|
02293 * |----- data[0] ----->|
02294 * |<--- ACK -----<|
02295 * |----- data[N-1] ----->|
02296 * |<--- ACK -----<|
02297 * |----- STOP ----->|
02298 * ```
02299 *
02300 * ## Common Use Cases
02301 *
02302 * | Use Case | Data Format |
02303 * |-----|-----|
02304 * | Config register write | [reg_addr, value] |
02305 * | Multi-byte register | [reg_addr, val0, val1, ...] |
02306 * | EEPROM page write | [addr_hi, addr_lo, data...] |
02307 * | Sensor command | [command_byte] |
02308 *
02309 * ## Error Handling
02310 *
02311 * On any error (timeout or NACK), the function issues a STOP condition
02312 * to release the bus before returning. The original error code is preserved.
02313 *
02314 *
02315 *
02316 *
02317 * @pre riic_init() called for this channel
02318 * @pre data != nullptr
02319 * @pre length >= 1 && length <= 256
02320 * @pre device_addr.value <= 127
02321 * @post On success: All bytes transferred, bus released
02322 * @post On failure: Bus released via STOP
02323 *
02324 * @note This is a blocking function - returns only after transfer complete.
02325 * @note STOP is always issued (success or failure) to release the bus.
02326 *
02327 * @warning NACK on address usually means device not present or wrong address.
02328 * @warning NACK on data may indicate device buffer full or write-protected.
02329 *
02330 * @par Example: Write Configuration Register

```

```

02331 * @code
02332 * // Write value 0x42 to register 0x05 of device at address 0x48
02333 * uint8_t config_data[2] = {0x05, 0x42}; // [reg_addr, value]
02334 * riic_channel_t channel = {.value = 0};
02335 * i2c_device_addr_t addr = {.value = 0x48};
02336 *
02337 * rx_err_t err = riic_write(channel, addr, config_data, 2);
02338 * if (err != k_rx_ok) {
02339 *     handle_i2c_error(err);
02340 * }

02431  * @brief Read data from an I2C peripheral device
02432  *
02433  * @details
02434  * Performs a complete I2C read transaction: START, address+R, receive data
02435  * bytes (ACK all except last), NACK last byte, STOP. This function is suitable
02436  * for reading device status, sensor data, or sequential memory reads where
02437  * the device auto-increments its internal pointer.
02438  *
02439  * ## Transaction Sequence
02440  *
02441  * ```
02442  * Controller                                Peripheral
02443  * |----- START ----->|
02444  * |--- Address + R (1) --->|
02445  * |<--- ACK -----<|
02446  * |<--- data[0] -----<|
02447  * |--- ACK ----->|
02448  * |<--- data[N-2] -----<|
02449  * |--- ACK ----->|
02450  * |<--- data[N-1] -----<|
02451  * |--- NACK ----->| <- Last byte
02452  * |--- STOP ----->|
02453  * ```
02454  *
02455  *
02456  * ## When to Use riic_read() vs riic_write_read()
02457  *
02458  * | Function | Use When |
02459  * |-----|-----|
02460  * | riic_read() | Device auto-increments address, or reading status |
02461  * | riic_write_read() | Need to specify register address first |
02462  *
02463  * ## Common Use Cases
02464  *
02465  * - Read device status register (if device supports direct read)
02466  * - Continue reading after previous write set address pointer
02467  * - Read from devices with auto-increment address mode
02468  *
02469  *
02470  *
02471  * @pre riic_init() called for this channel
02472  * @pre data != nullptr
02473  * @pre Buffer size >= length
02474  * @pre length >= 1 && length <= 256
02475  * @pre device_addr.value <= 127
02476  * @post On success: data contains received bytes, bus released
02477  * @post On failure: Bus released via STOP
02478  *
02479  * @note This is a blocking function - returns only after transfer complete.
02480  * @note NACK is automatically sent before reading last byte.
02481  *
02482  * @warning Most peripherals require riic_write_read() to specify which
02483  *         register to read from. Use this function only when the device
02484  *         supports direct reads or address auto-increment.
02485  *
02486  * @par Example: Read Temperature Sensor (Direct Read)
02487  * @code
02488  * // Read 2 bytes from temperature sensor at address 0x48
02489  * // (sensor auto-reports temperature on read)
02490  * uint8_t temp_data[2];
02491  * riic_channel_t channel = {.value = 0};
02492  * i2c_device_addr_t addr = {.value = 0x48};
02493  *
02494  * rx_err_t err = riic_read(channel, addr, temp_data, 2);
02495  * if (err == k_rx_ok) {
02496  *     int16_t raw = (temp_data[0] << 8) | temp_data[1];
02497  *     float celsius = raw * 0.0625f;
02498  * }
02499  * @endcode
02500  *
02501  * @see riic_init() Initialize channel before use
02502  * @see riic_write() Write-only transaction
02503  * @see riic_write_read() Combined write-then-read (register read)
02504  */

02615
02616 /**
02617  * @brief Combined write-then-read I2C transaction (register read)
02618  *
02619  * @details
02620  * Performs a complete I2C write-read transaction using a repeated START
02621  * condition. This is the most common pattern for reading registers from
02622  * I2C peripherals: write the register address, then read the data.
02623  *
02624  * ## Transaction Sequence (Register Read)
02625  *
02626  * ```
02627  * Controller                                Peripheral
02628  * |----- START ----->|
02629  * |----- Address + W (0) ----->|
02630  * |<--- ACK -----<|
02631  * |----- Register Address ----->| <- write_data
02632  * |<--- ACK -----<|
02633  * |----- REPEATED START ----->| <- No STOP!
02634  * |----- Address + R (1) ----->|
02635  * |<--- ACK -----<|
02636  * |<--- Register Data -----<| <- read_data
02637  * |----- ACK/NACK ----->|
02638  * |----- STOP ----->|
02639  * ```
02640  *
02641  * ## Why Repeated START?
02642  *
02643  * The repeated START (Sr) is critical for atomic register access:
02644  *
02645  * | Approach | Bus Release | Risk |
02646  * |-----|-----|-----|
02647  * | STOP + START | Yes | Another controller could interrupt |
02648  * | Repeated START | No | Transaction is atomic |
02649  *
02650  * Many I2C peripherals require repeated START and may not work correctly
02651  * with separate write-then-read transactions.
02652  *
02653  * ## Common Use Cases
02654  *
02655  * | Peripheral Type | write_data | read_length | Purpose |
02656  * |-----|-----|-----|-----|
02657  * | Temperature | [reg_addr] | 2 | Read temp register |
02658  * | EEPROM | [addr_hi, addr_lo] | N | Read N bytes |
02659  * | Accelerometer | [reg_addr] | 6 | Read XYZ axes |
02660  * | RTC | [seconds_reg] | 7 | Read time |
02661  *
02662  * @pre riic_init() called for this channel
02663  * @pre write_data != nullptr
02664  * @pre read_data != nullptr
02665  * @pre write_length >= 1 && write_length <= 256
02666  * @pre read_length >= 1 && read_length <= 256
02667  * @pre device_addr.value <= 127
02668  * @post On success: read_data contains register contents, bus released
02669  * @post On failure: Bus released via STOP
02670  *
02671  * @note This is a blocking function - returns only after transfer complete.
02672  * @note Uses repeated START (no bus release between write and read phases).
02673  * @note NACK is automatically sent before reading last byte.

```

```

02679 *
02680 * @par Example: Read WHO_AM_I Register from IMU
02681 * @code
02682 * // Read WHO_AM_I register (0x0F) from MPU6050 at address 0x68
02683 * riic_channel_t channel = {.value = 0};

RSPI transfer length and command register constants.

Functions

- static volatile `rx_rspi_regs_t` * `internal_get_rspi_base` (const `rspi_channel_t` channel)
Get RSPI register base address from channel number.
- static void `internal_set_mstpcrb_for_channel` (const `rspi_channel_t` channel, const bool enable)
Set module stop bit for an RSPI channel.
- static `rx_err_t` `internal_rspi_validate_init` (const `rspi_channel_t` channel, const `rspi_config_t` *const config, volatile `rx_rspi_regs_t` **rspi_out)
Initialize RSPI channel in peripheral mode.
- static `uint16_t` `internal_rspi_build_spcmd` (volatile `rx_rspi_regs_t` *const rspi, const `rspi_config_t` *const config)
Build SPCMD0 value and program SPDCR for the requested data width.
- static void `internal_rspi_release_module_stop` (const `rspi_channel_t` channel)
Release the MSTPCRB module-stop bit for the requested channel.
- `rx_err_t` `rspi_init_peripheral` (const `rspi_channel_t` channel, const `rspi_config_t` *config)
Initialize RSPI channel in peripheral mode for RPi5 communication.
- static `rx_err_t` `internal_wait_tx_ready` (volatile `rx_rspi_regs_t` *rspi)
Wait for transmit buffer to become empty (SPTEF flag).
- static `rx_err_t` `internal_wait_rx_ready` (volatile `rx_rspi_regs_t` *rspi)
Wait for receive buffer to become full (SPRF flag).
- `rx_err_t` `rspi_peripheral_transfer` (const `rspi_channel_t` channel, const `uint8_t` *tx_data, `uint8_t` *rx_data, const `uint16_t` length)
Perform full-duplex SPI transfer in peripheral mode.
- `rx_err_t` `rspi_peripheral_read_available` (const `rspi_channel_t` channel, bool *available)
Check if data is available in the RSPI receive buffer.

- rx_err_t [rspi_peripheral_write_ready](#) (const [rspi_channel_t](#) channel, bool *ready)
Check if transmit buffer is ready for data.
- rx_err_t [rspi_deinit](#) (const [rspi_channel_t](#) channel)
Deinitialize and disable RSPI peripheral.
- static void [internal_timing_delay](#) (const uint16_t cycles)
Cycle-accurate timing delay using inline NOP instructions.
- static void [internal_configure_spcmd](#) (uint16_t *spcmd, const uint8_t spi_mode)
Configure SPCMD register for SPI mode (CPOL/CPHA).
- static rx_err_t [internal_calculate_spbr](#) (const uint32_t freq_hz, uint8_t *spbr)
Calculate SPBR value for desired SPI clock frequency.
- static rx_err_t [internal_configure_cs_gpio](#) (const rx_port_pin_t pin_config)
Configure GPIO pin for chip select output.
- static rx_err_t [internal_validate_controller_args](#) (const [rspi_channel_t](#) channel, const [rspi_controller_config_t](#) *config)
Validate controller initialization arguments.
- static rx_err_t [internal_prepare_controller](#) (const [rspi_channel_t](#) channel, const [rspi_controller_config_t](#) *config, volatile [rx_rspi_regs_t](#) **out_rspi, uint8_t *out_spbr)
Prepare controller hardware resources.
- static rx_err_t [internal_configure_registers](#) (const [rspi_channel_t](#) channel, volatile [rx_rspi_regs_t](#) *rspi, uint8_t spbr, uint16_t spcmd, const [rspi_controller_config_t](#) *config)
Configure RSPI hardware registers for controller mode.
- rx_err_t [rspi_init_controller](#) (const [rspi_channel_t](#) channel, const [rspi_controller_config_t](#) *config)
Initialize RSPI channel in controller mode.
- rx_err_t [rspi_controller_set_cs](#) (const [rspi_channel_t](#) channel, const bool active)
Set chip select line state for RSPI controller channel.
- static rx_err_t [internal_controller_assert_cs_with_setup](#) (const [rspi_channel_t](#) channel)
Assert CS with setup delay.
- static rx_err_t [internal_controller_deassert_cs_with_hold](#) (const [rspi_channel_t](#) channel)
Deassert CS with hold delay.
- static rx_err_t [internal_controller_do_16bit_transfer](#) (volatile [rx_rspi_regs_t](#) *rspi, uint16_t tx_data, uint16_t *rx_data)
Perform core 16-bit SPI transfer operation.
- rx_err_t [rspi_controller_transfer_16bit](#) (const [rspi_channel_t](#) channel, const uint16_t tx_data, uint16_t *const rx_data)
Perform 16-bit SPI transfer in controller mode with CS handling.
- rx_err_t [rspi_controller_deinit](#) (const [rspi_channel_t](#) channel)
Deinitialize RSPI controller mode.

Variables

8.107.1 Detailed Description

RSPI (Renesas Serial Peripheral Interface) Driver for RX72N.

Provides complete SPI driver implementation supporting both peripheral mode (RX72N as SPI peripheral with RPi5 as controller) and controller mode (RX72N as SPI controller for sensor communication). Implements full-duplex communication with configurable clock frequency, SPI modes 0-3, and automatic chip select management.

System Architecture

Supported Features

Feature	Peripheral Mode	Controller Mode
Full-duplex	↔ [OK]↔	↔ [OK]↔
8-bit data	↔ [OK]↔	-
16-bit data	↔ [OK]↔	↔ [OK]↔

Feature	Peripheral Mode	Controller Mode
SPI modes 0-3	↔ [OK]↔	↔ [OK]↔
Hardware CS	-	GPIO-based
Clock config	External	100kHz - 10MHz

RSPI Channels

Channel	Use Case	Status Tracking
RSPI0	RPi5 communication	s_rspi_channel_initialized↔ [0]
RSPI1	Not used in current design	s_rspi_controller_initialized↔ [1]
RSPI2	Not used	Available

Performance Characteristics

Metric	Value	Condition
Max clock (controller)	10 MHz	PCLKB=60MHz, SPBR=2
Min clock (controller)	100 kHz	PCLKB=60MHz, SPBR=255
Transfer timeout	10 ms	Per byte
CS setup/hold delay	~300 ns	10 NOP cycles @ 240MHz
16-bit transfer time	~2-50 us	Depends on clock

Memory Usage

Component	Size	Description
Code (.text)	~4 KB	All functions
Constants (.rodata)	~100 B	Static constants
Static data (.bss)	~20 B	Init flags, CS config
Stack (per call)	~50 B	Local variables

Hardware Register Access

Uses [rx72n_rspi_regs.h](#) register definitions with inline accessors:

- [rspi0\(\)](#), [rspi1\(\)](#), [rspi2\(\)](#) for channel base addresses
- MSTPCRB module stop control for power management
- PRCR register protection for system register access

Module Dependencies

- [hardware.h](#): Hardware definitions and inline accessors
- [rx72n_regs.h](#): Register structure definitions
- [rx_gpio_constants.h](#): GPIO pin definitions
- [rx_port_constants.h](#): Port constants
- [rx_port_utils.h](#): Port/pin extraction utilities
- [rx_register_protection.h](#): PRCR unlock/lock

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion
- Rule 2: [OK] All loops bounded (timeout counters, transfer length max)
- Rule 3: [OK] No dynamic memory allocation (static buffers only)
- Rule 4: [OK] Functions under 60 lines (refactored into helpers)
- Rule 5: [OK] Minimum 2 assertions per function (RX_ASSERT, RX_CHECK_NULL_PTR)
- Rule 6: [OK] Variables declared at smallest scope
- Rule 7: [OK] All return values checked
- Rule 8: [OK] C23 typed enums for all constants
- Rule 9: [OK] No function pointers (direct hardware access)
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

SOLID Principles

- S (SRP): Driver handles only RSPI peripheral operations
- O (OCP): Mode/frequency configurable without code changes
- L (LSP): Peripheral/controller modes have consistent error semantics
- I (ISP): Separate init/transfer/deinit for each mode
- D (DIP): Depends on hardware abstractions ([rx72n_regs.h](#))

Thread Safety

- NOT thread-safe: Caller must provide external synchronization
- Static state (`s_rspi_*`) shared across calls
- Concurrent access to same channel requires mutex protection
- Different channels can be accessed independently

8.107.3 Enumeration Type Documentation

8.107.3.1 rspi_bit_constants_t

```
enum rspi\_bit\_constants\_t : uint32_t
```

RSPI bit manipulation constants for register field operations.

Provides named constants for single-bit set operations used to construct register masks via left-shift. Using a named constant instead of a literal 1 improves readability and grep-ability of register manipulation code. All register mask construction in this module uses `k_rspi_bit_set` as the base value to ensure consistent, self-documenting bit manipulation.

Invariant

`k_rspi_bit_set` must always equal 1

```
// Construct a mask for MSTPCRB module stop bit
uint32_t mask = (k_rspi_bit_set « k_rspi_mstpb_rspi0);
system_regs()->mstpcrb &= ~mask;
```

```

8.107.3.2 rspi_constants_t

```
enum rspi\_constants\_t : uint32_t
```

RSPI channel count, timeout, and general constants.

Core configuration constants for RSPI driver. Timeout values are calibrated for worst-case SPI peripheral response times at minimum clock frequency.

Timeout Calculation

At 100 kHz minimum clock, one byte takes ~80 us. 10 ms timeout provides ~125 byte margin before declaring failure, sufficient for any single transfer operation.

Since

Version 1.0.0

Enumerator

k_rspi_max_channels	Number of RSPI channels: RSPi0, RSPi1, RSPi2. Value: 3
k_rspi_timeout_us	Timeout for TX/RX wait operations in loop iterations. Approximately 10 ms at typical loop overhead. Value: 10000 iterations (~10 ms)
k_rspi_timeout_zero	Sentinel value indicating timeout has expired. Value: 0
k_rspi_len_zero	Sentinel for zero-length transfer (invalid). Value: 0
k_rspi_zero_u32	Zero constant for uint32_t comparisons. Value: 0
k_rspi_spbr_offset	Offset for SPBR calculation formula. $SPBR = (PCLKB / (2 * freq)) - 1$ Value: 1
k_rspi_loop_start	Starting index for bounded loops (NASA Rule 2). Value: 0

Definition at line 176 of file [rspi.c](#).

00214 } rspi_mstpcrb_bits_t;
```

8.107.3.7 rspi`mstpcrc`bits`t

```
enum rspi\_mstpcrc\_bits\_t : uint8_t
```

RSPI2 module stop bit position in MSTPCRC (HW Manual p.410).

Enumerator

k_rspi_mstpc_rspi2	RSPI2 module stop bit in MSTPCRC
--------------------	----------------------------------

Definition at line 217 of file [rspi.c](#).

```
00217      : uint8_t {
00218  k_rspi_mstpc_rspi2 = 22, /**< RSPI2 module stop bit in MSTPCRC */
00219 } rspi_mstpcrc_bits_t;
```

8.107.3.8 `rspi_register_defaults_t`

```
enum rspi\_register\_defaults\_t : uint8_t
```

RSPI register default values (reset/disabled state).

Values written to RSPI registers during initialization to establish a known baseline configuration. These match the hardware reset defaults documented in the RX72N Hardware Manual Section 38.2. Writing these values before configuring mode-specific settings ensures a deterministic starting state regardless of prior peripheral activity.

Invariant

All values must match the hardware manual reset state

```
// Reset RSPI registers to defaults before reconfiguration
rspi->sppcr = k_rspi_sppcr_no_loopback;
rspi->sprcr = k_rspi_sprcr_disabled;
```

See also

Since

Version 1.0.0

Enumerator

<code>k_rspi_sppcr_no_loopback</code>	SPPCR: no loopback mode (normal operation)
<code>k_rspi_sprcr_disabled</code>	SPCR: SPI disabled (module in reset state)

Definition at line 282 of file [rspi.c](#).

```
00282     : uint8_t {
00283   k_rspi_sppcr_no_loopback = 0U, /**< SPPCR: no loopback mode (normal operation) */
00284   k_rspi_sprcr_disabled    = 0U, /**< SPCR: SPI disabled (module in reset state) */
00285 } rspi_register_defaults_t;
```

8.107.3.9 `rspi_spcmd_bits_t`

```
enum rspi\_spcmd\_bits\_t : uint16_t
```

SPCMD register bit positions and masks.

Enumerator

<code>k_rspi_spcmd_cpha_mask</code>	CPHA bit mask (bit 0)
<code>k_rspi_spcmd_cpol_mask</code>	CPOL bit mask (bit 1)
<code>k_rspi_spcmd_cpol_pos</code>	CPOL bit position
<code>k_rspi_spcmd_cpha_pos</code>	CPHA bit position

k_rspi_spcmd_spl_shift	SPL (data length) bit shift
k_rspi_spcmd_8bit	8-bit data length value
k_rspi_spcmd_16bit	16-bit data length value

Definition at line 243 of file [rspi.c](#).

```
00243      : uint16_t {
00244  k_rspi_spcmd_cpha_mask = 1U, /**< CPHA bit mask (bit 0) */
00245  k_rspi_spcmd_cpol_mask = 2U, /**< CPOL bit mask (bit 1) */
00246  k_rspi_spcmd_cpol_pos  = 1, /**< CPOL bit position */
00247  k_rspi_spcmd_cpha_pos  = 0, /**< CPHA bit position */

00250  k_rspi_spcmd_16bit     = 15U, /**< 16-bit data length value */
00251 } rspi_spcmd_bits_t;
```

8.107.3.10 rspi`spdcr`local`t

```
enum rspi\_spdcr\_local\_t : uint8_t
```

SPDCR register bit positions (local).

Enumerator

k_rspi_spdcr_splw_pos	SPLW bit position (longword/32-bit access)
k_rspi_spdcr_byte_mode	Byte access mode

Definition at line 254 of file [rspi.c](#).

```
00254      : uint8_t {
00255  k_rspi_spdcr_splw_pos = 5, /**< SPLW bit position (longword/32-bit access) */
00256  k_rspi_spdcr_byte_mode = 0U, /**< Byte access mode */
00257 } rspi_spdcr_local_t;
```

8.107.3.11 rspi`transfer`constants`t

```
enum rspi\_transfer\_constants\_t : uint16_t
```

RSPI transfer length and command register constants.

Defines limits and initialization values for the RSPI transfer engine. The maximum transfer length is constrained by the 16-bit DMA counter. SPCMD initial value sets a clean baseline before configuring bit fields for CPOL, CPHA, and data length via bitwise OR operations.

Invariant

k_rspi_transfer_len_max must equal 65535 (uint16_t maximum, 16-bit DMA counter limit)

```
// Validate transfer length before starting peripheral transfer
if (length == k_rspi_len_zero || length > k_rspi_transfer_len_max) {
    return k_rx_err_invalid_arg;
}
// Initialize SPCMD before configuring mode-specific bits
uint16_t spcmd = k_rspi_spcmd_init;
```

```

8.107.4 Function Documentation

8.107.4.1 internal_calculate_spbr()

```
rx_err_t internal_calculate_spbr (
    const uint32_t freq_hz,
    uint8_t * spbr) [static]
```

Calculate SPBR value for desired SPI clock frequency.

Computes the RSPI Bit Rate Register (SPBR) value required to achieve the desired SPI clock frequency. Uses the formula: $SPBR = (PCLKB / (2 * freq_hz)) - 1$ with BRDV=0 (no additional divisor). The result is validated against the hardware-supported range [0, 255].

Precondition

`spbr` must be a valid non-null pointer
`freq_hz` must be in range [100000, 10000000] Hz

Postcondition

`*spbr` contains the calculated SPBR value if `k_rx_ok` returned
`*spbr` is unchanged on error

Note

Not thread-safe. Caller must provide synchronization.

8.107.4.2 internal`configure`cs`gpio()

```

rx_err_t internal_configure_cs_gpio (
    const rx_port_pin_t pin_config) [static]
```

Configure GPIO pin for chip select output.

Configures a GPIO pin as a digital output for use as an active-low SPI chip select signal. Extracts port and pin numbers from the type-safe `rx_port_pin_t` encoding, sets the pin direction to output via PDR, and drives the pin high (CS inactive) via PODR.

Precondition

`pin_config` must encode a valid port (0-J) and pin (0-7)

Port hardware must be available and not module-stopped

Postcondition

GPIO PDR bit set (output direction)
 GPIO PODR bit set (CS inactive / high)

Note

Not thread-safe. Caller must provide synchronization for port access.

Here is the caller graph for this function:

8.107.4.3 internal_configure_registers()

```

rx_err_t internal_configure_registers (
    const rspi\_channel\_t channel,

```

```
volatile rx_rspi_regs_t * rspi,
uint8_t spbr,
uint16_t spcmd,
const rspi_controller_config_t * config)  [static]
```

Configure RSPI hardware registers for controller mode.

Performs the complete RSPI hardware register configuration sequence for controller mode. Enables the module clock, disables SPI for safe register modification, programs bit rate, command, data control and pin control registers, then enables SPI in controller mode. Also stores the CS pin configuration and marks the channel as initialized. The register write order follows the RX72N Hardware Manual Section 38.3.6 initialization procedure.

Precondition

rspi must be a valid non-null pointer from [internal_get_rspi_base\(\)](#)
 spbr must be pre-calculated by [internal_calculate_spbr\(\)](#)
 spcmd must be pre-configured with CPOL/CPHA and data length bits

Postcondition

RSPI module clock enabled, registers configured, SPI enabled
 s_rspi_cs_config[channel] stores CS port and pin
 s_rspi_controller_initialized[channel] set to true

Note

Not thread-safe. Caller must provide synchronization.

Warning

PRCR register protection is temporarily unlocked during this call.

8.107.4.4 internal'configure'spcmd()

```
void internal_configure_spcmd (
    uint16_t * spcmd,
    const uint8_t spi_mode) [static]
```

Configure SPCMD register for SPI mode (CPOL/CPHA).

Sets CPOL and CPHA bits in an SPCMD register value based on SPI mode (0-3). The SPI mode encodes clock polarity (CPOL) and clock phase (CPHA) per the standard SPI specification. Bits are set via bitwise OR so pre-existing fields in the SPCMD value (such as data length) are preserved.

Mode	CPOL	CPHA	Clock Idle	Data Sampled
0	0	0	Low	Rising edge
1	0	1	Low	Falling edge
2	1	0	High	Falling edge
3	1	1	High	Rising edge

Precondition

spcmd must be a valid non-null pointer
 spi_mode must be in range [0, 3] (only bits 0-1 used)

Postcondition

spcmd CPOL/CPHA bits set according to spi_mode
 Other spcmd bits remain unchanged

Note

Not thread-safe. Caller must provide synchronization.

8.107.4.5 internal_controller_assert_cs_with_setup()

```

rx_err_t internal_controller_assert_cs_with_setup (
    const rspi\_channel\_t channel) [static]

```

Assert CS with setup delay.

Asserts the chip select line (drives low for active-low CS) and then applies a cycle-accurate setup time delay using NOP instructions. The setup delay ensures the SPI peripheral has sufficient time to recognize CS assertion before clock transitions begin. Delay is calibrated for ~300ns at 240 MHz core clock.

Precondition

Channel must be initialized via [rspi_init_controller\(\)](#)
[s_rspi_controller_initialized\[channel\]](#) must be true

Postcondition

CS GPIO pin driven low (active)
 Minimum setup delay of ~300ns has elapsed

Note

Not thread-safe. Caller must provide synchronization.

[internal_timing_delay\(\)](#) Provides cycle-accurate delay
[k_rspi_cs_setup_delay](#) Setup delay iteration count

Since

Version 1.0.0

CS setup time delay (~300ns). Inline assembly NOP is used to produce precise, cycle-accurate timing that C-level delays cannot guarantee. SPI peripherals typically require minimum CS setup time before SCLK transitions. Loop count `k_rspi_cs_setup_delay` is calibrated for RX72N at 240 MHz (4.17ns per cycle).

8.107.4.6 internal`controller`deassert`cs`with`hold()

```
rx_err_t internal_controller_deassert_cs_with_hold (
    const rspi\_channel\_t channel) [static]
```

Deassert CS with hold delay.

Applies a cycle-accurate hold time delay using NOP instructions, then deasserts the chip select line (drives high for active-low CS). The hold delay ensures the SPI peripheral has sufficient time to latch the final data bit before CS is released. Delay is calibrated for ~300ns at 240 MHz core clock.

Precondition

Channel must be initialized via [rspi_init_controller\(\)](#)
[s_rspi_controller_initialized\[channel\]](#) must be true

Postcondition

Minimum hold delay of $\sim 300\text{ns}$ has elapsed
 CS GPIO pin driven high (inactive)

Note

Not thread-safe. Caller must provide synchronization.

8.107.4.7 internal`controller`do`16bit`transfer()

```

rx_err_t internal_controller_do_16bit_transfer (
    volatile rx_rspi_regs_t * rspi,
    uint16_t tx_data,
    uint16_t * rx_data) [static]

```

Perform core 16-bit SPI transfer operation.

Executes a single full-duplex 16-bit SPI transfer without chip select management. Waits for the transmit buffer to become empty, writes 16-bit data to SPDR, waits for the receive buffer to fill, reads the 16-bit response from SPDR, and clears SPRF and OVRF status flags. This is the inner transfer primitive used by `rspi_controller_transfer_16bit()` after CS assertion and before CS deassertion.

Precondition

rspi must be a valid non-null pointer to initialized RSPI registers
 SPI must be enabled (SPCR.SPE=1) before calling

Postcondition

*rx_data contains the 16-bit value received during the transfer
 SPSR flags SPRF and OVRF are cleared

Note

Not thread-safe. Caller must provide synchronization.

8.107.4.8 internal`get`rspi`base()

```
volatile rx_rspi_regs_t * internal_get_rspi_base (
    const rspi_channel_t channel)  [static]
```

Get RSPI register base address from channel number.

Maps a channel index (0-2) to the corresponding RSPI peripheral register block via the inline accessor functions `rspi0()`/`rspi1()`/`rspi2()`. Returns nullptr for out-of-range channel numbers to allow callers to detect invalid input without risking a wild pointer dereference.

Precondition

- channel must be in range [0, k_rspi_max_channels)
- RSPI hardware must be present (RX72N 144-pin package)

Postcondition

- Returned pointer (if non-null) is aligned and points to valid HW registers
- No side effects on hardware state

Note

- Not thread-safe. Caller must provide synchronization if needed.

8.107.4.9 `internal_prepare_controller()`

```
rx_err_t internal_prepare_controller (
    const rspi\_channel\_t channel,
    const rspi\_controller\_config\_t * config,
    volatile rx\_rspi\_regs\_t ** out_rspi,
    uint8_t * out_spbr) [static]
```

Prepare controller hardware resources.

Calculates the SPBR register value for the requested clock frequency, validates the RSPI register base address for the given channel, and configures the CS GPIO pin as an active-low output. Operations are ordered so that a failure in SPBR calculation avoids unnecessary GPIO configuration, and RSPI base validation occurs before GPIO setup to avoid leaving GPIO configured if the channel is invalid.

Precondition

config must be validated by [internal_validate_controller_args\(\)](#) first
channel must be in range [0, k_rspi_max_channels)

Postcondition

*out_rspi points to valid RSPI register base on success
*out_spbr contains calculated SPBR value on success
CS GPIO pin configured as output, driven high (inactive) on success

Note

Not thread-safe. Caller must provide synchronization.

```
uint16_t internal_rspi_build_spcmd (
    volatile rx_rspi_regs_t *const rspi,
    const rspi_config_t *const config) [static]
```

Build SPCMD0 value and program SPDCR for the requested data width.

Encodes CPOL/CPHA bits from spi_mode and selects 8-bit or 16-bit data length. SPDCR is set to longword access for 16-bit transfers, byte access for 8-bit, matching the SPCMD0 SPL field.

Parameters

in	rspi	Peripheral base (non-null)
in	config	Validated init config

Returns

uint16_t Encoded SPCMD0 value

Precondition

SPCR.SPE=0 (caller has already disabled SPI)

Postcondition

SPDCR programmed; SPCMD0 not yet written

Since

Version 1.0.0

Definition at line 556 of file [rspi.c](#).

8.107.4.11 `internal_rspi_release_module_stop()`

```
void internal_rspi_release_module_stop (
    const rspi\_channel\_t channel)  [static]
```

Release the MSTPCRB module-stop bit for the requested channel.

Wraps the protected-register PRCR unlock/lock around the MSTPCRB write that clears the channel's clock gate.

Parameters

in	channel	Validated channel index
----	---------	-------------------------

Precondition

`channel < k_rspi_max_channels`

Postcondition

Channel module clock running

Since

Version 1.0.0

Definition at line 594 of file [rspi.c](#).

```
00595 {
00596   *prcr_reg() = k_rx_prcr_unlock_prc1_prc3;

8.107.4.12 internal`rspi`validate`init()

```
rx_err_t internal_rspi_validate_init (
    const rspi_channel_t channel,
    const rspi_config_t *const config,
    volatile rx_rspi_regs_t ** rspi_out)  [static]
```

Initialize RSPI channel in peripheral mode.

Configures the specified RSPI channel as a SPI peripheral to communicate with the Raspberry Pi 5 (acting as SPI Controller). Enables the peripheral in the configured SPI mode (0-3) with optional 8-bit or 16-bit data frames. Uses register protection unlock/lock for module stop control.

Precondition

config pointer must be non-NULL
channel must be in range [0, k_rspi_max_channels)
config->spi_mode must be in range [0, 3]

Postcondition

If successful:

- RSPI module is enabled (module stop bit cleared via register protection)
- SPI mode (CPOL/CPHA) is configured per config->spi_mode
- Data frame length (8-bit or 16-bit) is set per config->use_16bit
- SPI is enabled in peripheral mode (SPCR.MSTR = 0)
- s_rspi_channel_initialized[channel] is set to true
- Peripheral is ready to receive transfers from SPI controller

Validate rspi_init_peripheral inputs and resolve peripheral base

Parameters

in	channel	Channel index
in	config	Caller's config (must be non-null)
out	rspi_out	On success, set to peripheral base

Returns

rx_err_t Error code

Return values

k_rx_ok	All checks pass
k_rx_err_null_ptr	config is nullptr
k_rx_err_invalid_arg	Bounds violation or unknown channel

Precondition

`rspi_out` non-null

Since

Version 1.0.0

8.107.4.13 `internal_set_mstpcrb_for_channel()`

```
void internal_set_mstpcrb_for_channel (
    const rspi\_channel\_t channel,
    const bool enable)    [static]
```

Set module stop bit for an RSPI channel.

Controls the Module Stop Control Register bits that gate the clock to each RSPI channel. RSPI0 and RSPI1 are in MSTPCRB (bits 17 and 16); RSPI2 is in MSTPCRC (bit 22). Clearing a bit enables the module (starts the clock); setting it stops the module (reduces power consumption).

Precondition

[system_regs\(\)](#) must return a valid pointer
channel must be one of `k_rspi_channel_0`, `k_rspi_channel_1`, `k_rspi_channel_2`

Postcondition

MSTPCRB (channels 0/1) or MSTPCRC (channel 2) updated appropriately
Module clock enabled or disabled for the specified channel

Note

Not thread-safe. Caller must hold MSTPCR protection if applicable.

Warning

Disabling a module while it is actively transferring data will cause undefined hardware behavior.

8.107.4.14 internal_timing_delay()

```

void internal_timing_delay (
    const uint16_t cycles) [static]

```

Cycle-accurate timing delay using inline NOP instructions.

Produces precise delays using inline assembly NOP operations for SPI timing requirements (CS setup/hold times). Each NOP cycle is 4.17 ns at 240 MHz core clock.

Precondition

- cycles must be non-zero
- cycles must not exceed `k_rspi_max_delay_cycles`

Postcondition

Minimum delay of (cycles * 4.17 ns) has elapsed
 No hardware state modified

Note

Timing is cycle-accurate on RX72N @ 240 MHz (4.17 ns per cycle)
 Using inline ASM ensures compiler does not optimize away the loop

Warning

Only accurate when compiled with known optimization level (-O2)

8.107.4.15 `internal_validate_controller_args()`

```
rx_err_t internal_validate_controller_args (
    const rspi\_channel\_t channel,
    const rspi\_controller\_config\_t * config) [static]
```

Validate controller initialization arguments.

Performs comprehensive input validation for [rspi_init_controller\(\)](#) before any hardware modification occurs. Checks null pointer, channel range, duplicate initialization, and SPI mode range. Centralizes validation logic to keep the public API function concise.

Precondition

config may be nullptr (will be detected and rejected)
 channel may be out of range (will be detected and rejected)

Postcondition

No hardware state modified (validation only)
[s_rspi_controller_initialized\[\]](#) not modified

Note

Not thread-safe. Caller must provide synchronization.

8.107.4.16 `internal_wait_rx_ready()`

```
rx_err_t internal_wait_rx_ready (
    volatile rx\_rspi\_regs\_t * rspi) [static]
```

Wait for receive buffer to become full (SPRF flag).

Polls the SPSR.SPRF (SPI Receive Buffer Full Flag) in a busy-wait loop with a configurable timeout. When SPRF is set, received data is available in the SPDR register and can be read. The timeout prevents infinite loops if the SPI peripheral is stuck or no clock is being generated.

Precondition

- rspi must be a valid non-null pointer to initialized RSPI registers
- A transfer must be in progress or complete for SPRF to set

Postcondition

- No hardware state modified (read-only polling of SPSR)
- Timeout counter decremented to reflect remaining iterations

Note

- Not thread-safe. Caller must provide synchronization.

Warning

- Busy-wait loop; do not call from time-critical ISR context.

8.107.4.17 `internal_wait_tx_ready()`

```
rx_err_t internal_wait_tx_ready (
    volatile rx_rspi_regs_t * rspi) [static]
```

Wait for transmit buffer to become empty (SPTEF flag).

Polls the SPSR.SPTEF (SPI Transmit Buffer Empty Flag) in a busy-wait loop with a configurable timeout. When SPTEF is set, the transmit buffer is empty and ready to accept new data via SPDR. The timeout prevents infinite loops if the SPI peripheral is stuck.

Precondition

`rspi` must be a valid non-null pointer to initialized RSPI registers
 RSPI module clock must be enabled (MSTPCRB bit cleared)

Postcondition

No hardware state modified (read-only polling of SPSR)
 Timeout counter decremented to reflect remaining iterations

Note

Not thread-safe. Caller must provide synchronization.

Warning

Busy-wait loop; do not call from time-critical ISR context.

8.107.4.18 `rspi_controller_deinit()`

```
rx_err_t rspi_controller_deinit (
    const rspi\_channel\_t channel)  [nodiscard]
```

Deinitialize RSPI controller mode.

Deinitialize and disable an RSPI controller-mode channel.

Disables the RSPI controller, deasserts chip select, clears configuration, and stops the module to reduce power consumption.

Precondition

Should be called after [rspi_init_controller\(\)](#) to properly clean up

Postcondition

If successful:

- CS is deasserted via `rspi_controller_set_cs(channel, false)`
- RSPI is disabled (`rspi->spr = k_rspi_spr_disabled`)
- Module clock is stopped via [internal_set_mstpcrb_for_channel\(\)](#)
- `s_rspi_cs_config[channel]` is cleared (`port=0`, `pin=0`)
- `s_rspi_controller_initialized[channel] = false`
- Register protection is unlocked/locked via `*prcr_reg()`

Note

Thread-safe only if caller ensures no concurrent access to the same channel

Here is the caller graph for this function:

8.107.4.20 rspi_controller_transfer_16bit()

```

rx_err_t rspi_controller_transfer_16bit (
    const rspi_channel_t channel,
    const uint16_t tx_data,
    uint16_t *const rx_data) [nodiscard]

```

Perform 16-bit SPI transfer in controller mode with CS handling.

Perform a 16-bit full-duplex SPI transfer in controller mode with automatic CS.

Executes a full-duplex 16-bit SPI transfer with automatic chip select assertion/deassertion and timing delays.

Sequence:

1. Assert CS (active low) with setup delay (~300ns)
2. Wait for TX buffer ready, then transmit 16-bit data
3. Wait for RX buffer full, then read 16-bit response
4. Hold CS for minimum hold time (~300ns)
5. Deassert CS (inactive high)
6. Clear status flags

Precondition

Channel must be initialized via [rspi_init_controller\(\)](#)

rx_data must be a valid non-nullptr

Postcondition

If successful:

- rx_data is filled with received 16-bit value
- Status flags (SPRF, OVRF) are cleared
- CS is deasserted (high)

On error:

- CS is deasserted if possible
- rx_data contents are undefined

Note

CS setup delay: k_rspi_cs_setup_delay NOP loops (~300ns)

CS hold delay: k_rspi_cs_hold_delay NOP loops (~300ns)

Uses inline assembly NOP for precise timing control

Definition at line 1600 of file [rspi.c](#).

8.107.4.21 rspi_deinit()

```
rx_err_t rspi_deinit (
    const rspi\_channel\_t channel) [nodiscard]
```

Deinitialize and disable RSPI peripheral.

Deinitialize and disable an RSPI peripheral-mode channel.

Disables the specified RSPI channel, clears the initialization flag, and optionally disables the module (via module stop bit) to reduce power consumption.

Precondition

Channel should have been initialized via [rspi_init_peripheral\(\)](#) previously

Postcondition

If successful:

- RSPI peripheral is disabled (SPCR.SPE = 0)
- `s_rspi_channel_initialized[channel]` is set to false
- Channel is no longer available for SPI operations

Definition at line 884 of file [rspi.c](#).

```

8.107.4.22 rspi_init_controller()

```

rx_err_t rspi_init_controller (
    const rspi_channel_t channel,
    const rspi_controller_config_t * config) [nodiscard]

```

Initialize RSPI channel in controller mode.

Initialize RSPI channel in controller mode for external device communication.

Configures the specified RSPI channel as a SPI controller to communicate with SPI peripheral devices. Enables the module, configures clock frequency, SPI mode, and chip select GPIO pin.

Precondition

config must be non-NULL
channel < k_rspi_max_channels
channel must not be already initialized
CS GPIO port and pin must be valid and available

Postcondition

If successful:

- RSPI module is enabled via [internal_set_mstpcrb_for_channel\(\)](#)
- *prcr_reg() is unlocked/locked for register protection
- RSPI registers configured: spbr, spcmd0, spcr, spdcr, sppcr
- CS GPIO configured as output, driven high (inactive)
- s_rspi_cs_config[channel] stores CS port/pin
- s_rspi_controller_initialized[channel] = true

On error:

- Hardware state is unchanged
- Channel remains uninitialized

Note

Bit rate calculation: $\text{freq} = \text{PCLKB} / (2 * (\text{SPBR} + 1))$

Always configures 16-bit data frames with word access mode

CS is active-low (asserted=0, deasserted=1)

Here is the call graph for this function:

8.107.4.23 rspi_init_peripheral()

```

rx_err_t rspi_init_peripheral (
    rspi_channel_t channel,
    const rspi_config_t * config) [nodiscard]

```

Initialize RSPI channel in peripheral mode for RPi5 communication.

Configures the specified RSPI channel as an SPI peripheral device. In peripheral mode the RX72N receives the clock signal from an external SPI controller (Raspberry Pi 5). Performs full hardware initialization including module stop release, pin function selection (COPI/CIPO/CLK/CS via MPC), SPI mode register configuration, and frame size setup.

8.107.4.24 Algorithm

1. Validate channel (0-2) and config pointer
2. Release RSPI module from module stop (MSTPCRB)
3. Disable RSPI (SPCR.SPE = 0)
4. Configure pin functions via MPC (COPI, CIPO, CLK, CS)
5. Set SPI mode (CPOL/CPHA in SPCMD0)
6. Set frame length (8-bit or 16-bit in SPCMD0)

7. Configure as peripheral (SPCR.MSTR = 0)
8. Enable RSPI (SPCR.SPE = 1)

Parameters

in	channel	RSPI channel number (0-2)
in	config	Pointer to peripheral mode configuration • Must not be nullptr • config->spi_mode must be valid (0-3)

Returns

rx_err_t Error code indicating success or failure

Return values

k_rx_ok	Channel successfully initialized in peripheral mode
k_rx_err_invalid_arg	Channel > 2 or invalid SPI mode
k_rx_err_null_ptr	config pointer is nullptr
k_rx_err_invalid_state	Channel already initialized (call rspi_deinit() to reinitialize)

Precondition

Channel must not be already initialized (call [rspi_deinit\(\)](#) first to reinitialize)
 System clocks must be configured (PCLKB running at expected frequency)

Postcondition

RSPI channel configured as SPI peripheral, ready for transfers
 COPI/CIPO/CLK/CS pins configured for SPI peripheral function

Note

Thread Safety: NOT thread-safe. Initialize each channel from a single thread during system startup.

Example: RPi5 Communication Setup

```
rspi_config_t rpi_cfg = {
    .spi_mode = k_rspi_mode_0,
    .use_16bit = false
};
rx_err_t err = rspi_init_peripheral(k_rspi_channel_0, &rpi_cfg);
if (err != k_rx_ok) {
    rx_log_error_val("SPI", "RSPI0 peripheral init failed", err);
}
```

8.107.4.26 `rspi_peripheral_transfer()`

```

rx_err_t rspi_peripheral_transfer (
    const rspi_channel_t channel,
    const uint8_t * tx_data,
    uint8_t * rx_data,
    const uint16_t length) [nodiscard]

```

Perform full-duplex SPI transfer in peripheral mode.

Full-duplex SPI transfer in peripheral mode.

Executes a full-duplex (simultaneous transmit and receive) SPI transfer on the specified RSPI channel operating in peripheral mode. Transfers data byte-by-byte with timeout protection on both transmit buffer ready and receive buffer full operations.

Precondition

- channel must be initialized via `rspi_init_peripheral()` before calling
- tx_data pointer must be non-NULL
- rx_data pointer must be non-NULL
- length must be in range [1, 65535]

Postcondition

- If successful, rx_data buffer is filled with received bytes corresponding to transmitted data at each byte offset

Definition at line 742 of file `rspi.c`.

00092 *
00093 * @par Hardware Register Access
00094 * - Uses rx72n_rspi_regs.h register definitions with inline accessors:
00095 * - rspi0(), rspi1(), rspi2() for channel base addresses
00096 * - MSTPCRB module stop control for power management
00097 * - PRCR register protection for system register access
00098 *
00099 * @par Module Dependencies
00100 * - hardware.h: Hardware definitions and inline accessors
00101 * - rx72n_regs.h: Register structure definitions
00102 * - rx_gpio_constants.h: GPIO pin definitions
00103 * - rx_port_constants.h: Port constants
00104 * - rx_port_utils.h: Port/pin extraction utilities
00105 * - rx_register_protection.h: PRCR unlock/lock
00106 *
00107 * @par NASA Power of 10 Compliance
00108 * - Rule 1: [OK] No goto, setjmp, or recursion
00109 * - Rule 2: [OK] All loops bounded (timeout counters, transfer length max)
00110 * - Rule 3: [OK] No dynamic memory allocation (static buffers only)
00111 * - Rule 4: [OK] Functions under 60 lines (refactored into helpers)
00112 * - Rule 5: [OK] Minimum 2 assertions per function (RX_ASSERT, RX_CHECK_NULL_PTR)
00113 * - Rule 6: [OK] Variables declared at smallest scope
00114 * - Rule 7: [OK] All return values checked
00115 * - Rule 8: [OK] C23 typed enums for all constants
00116 * - Rule 9: [OK] No function pointers (direct hardware access)
00117 * - Rule 10: [OK] Compiles with -Wall -Wextra -Werror
00118 *
00119 * @par SOLID Principles
00120 * - **S (SRP):** Driver handles only RSPI peripheral operations
00121 * - **O (OCP):** Mode/frequency configurable without code changes
00122 * - **L (LSP):** Peripheral/controller modes have consistent error semantics
00123 * - **I (ISP):** Separate init/transfer/deinit for each mode
00124 * - **D (DIP):** Depends on hardware abstractions (rx72n_regs.h)
00125 *
00126 * @par Thread Safety
00127 * - **NOT thread-safe:** Caller must provide external synchronization
00128 * - Static state (s_rspi_*) shared across calls

```

```

00129 * - Concurrent access to same channel requires mutex protection
00130 * - Different channels can be accessed independently

Include dependency graph for rx_cac.c:

Functions

- static void [internal_module_start](#) (void)
Release the CAC module from module-stop (MSTPCRC.MSTPC19 = 0).
- static void [internal_module_stop](#) (void)
Return the CAC module to module-stop (MSTPCRC.MSTPC19 = 1).
- static void [internal_apply_config](#) (const [rx_cac_config_t](#) *config)
Program CACR1, CACR2, CAULVR, CALLVR, and CAICR from a config struct.
- rx_err_t [rx_cac_init](#) (const [rx_cac_config_t](#) *config)
Initialize the CAC module with the supplied configuration.
- rx_err_t [rx_cac_start](#) (void)
Start the CAC measurement (implementation).
- rx_err_t [rx_cac_stop](#) (void)
Pause the CAC measurement (implementation).
- bool [rx_cac_check](#) (uint32_t *out_count)
Check the CAC frequency-error flag and snapshot count (implementation).
- rx_err_t [rx_cac_deinit](#) (void)
Fully deinitialize the CAC peripheral (implementation).

Variables

- static const char *const `s_tag` = "CAC"
Log tag for the CAC driver module.
- static bool `s_initialized` = false
Tracks whether `rx_cac_init()` has installed a valid configuration.
- static const uint8_t `s_fmcs_table` []
CACR1.FMCS bit pattern indexed by `rx_cac_clock_t`.
- static const uint8_t `s_rscs_table` []
CACR2.RSCS bit pattern indexed by `rx_cac_clock_t` (reference subset).
- static const uint8_t `s_tcscs_table` []
CACR1.TCSS bit pattern indexed by `rx_cac_target_div_t`.
- static const uint8_t `s_rcds_table` []
CACR2.RCDS bit pattern indexed by `rx_cac_ref_div_t`.

8.109.1 Detailed Description

Clock Frequency Accuracy Measurement Circuit (CAC) Driver Implementation.

Driver for the RX72N Clock Frequency Accuracy Measurement Circuit (CAC) per Renesas RX72N Group User's Manual (R01UH0824EJ0111) Chapter 11 "Clock Frequency Accuracy Measurement Circuit" (pp.↵ 392-397 of the Ch11 register map section referenced below).

The CAC compares a measurement-target clock against a reference clock, counts target-clock edges between reference-clock edges, and compares the accumulated count against CAULVR / CALLVR window bounds. A frequency deviation sets CASTR.FERRF; when CAICR.FERRIE is enabled the failure is routed through GROUPL0 (vector 110, bit 26) to the CPU.

Bring-up Sequence (RX72N HW Manual Ch11.3)

1. Unlock PRCR.PRC1, clear MSTPCRC.MSTPC19, re-lock PRCR.
2. Ensure CACR0.CFME = 0 while programming CACR1, CACR2, CAULVR, CALLVR, and CAICR. Writes to CAULVR / CALLVR require CFME = 0.
3. Clear any stale CASTR flags via CAICR write-1-clear bits.
4. Caller invokes `rx_cac_start()` to set CACR0.CFME = 1 and begin measuring.

NASA Power of 10 Compliance

- Rule 1: [OK] No goto / setjmp / recursion
- Rule 2: [OK] No loops
- Rule 3: [OK] Zero dynamic memory allocation
- Rule 4: [OK] All functions < 60 lines
- Rule 5: [OK] >= 2 validation checks per function
- Rule 6: [OK] File-scope statics, narrowest-scope locals
- Rule 7: [OK] All return values checked via RX_RETURN_ON_ERROR / explicit cast
- Rule 8: [OK] C23 typed enums for constants
- Rule 9: [OK] Single-level pointers
- Rule 10: [OK] -Wall -Wextra -Werror clean

8.109.2.1 `internal`apply`config()`

```
void internal__apply__config (  
    const rx\_cac\_config\_t * config)    [static]
```

Program CACR1, CACR2, CAULVR, CALLVR, and CAICR from a config struct.

Precondition

config != nullptr and all enum fields validated by [rx_cac_init\(\)](#)
CACR0.CFME == 0 (writes to CAULVR/CALLVR require measurement halted)

Postcondition

Registers hold the requested configuration and CASTR flags are cleared

Since

Version 1.0.0

Definition at line 194 of file [rx_cac.c](#).

```

00195 {
00196     volatile rx_cac_regs_t* regs = cac();
00197     uint8_t      cacr1_val =
00198         (uint8_t)(s_fmcs_table[(uint8_t)config->measured_clock] |

Here is the caller graph for this function:

8.109.2.2 internal module start()

```

void internal_module_start (
    void ) [static]

```

Release the CAC module from module-stop (MSTPCRC.MSTPC19 = 0).

Unlocks PRC1, clears the MSTPC19 bit, re-locks PRCR.

Precondition

PRCR is accessible (not held by another critical section)

Postcondition

MSTPCRC.MSTPC19 = 0, PRCR re-locked

Since

Version 1.0.0

Definition at line 166 of file [rx_cac.c](#).

```
00167 {
00168  *prcr_reg() = k_rx_prcr_unlock_prc1;

Here is the caller graph for this function:

8.109.2.4 rx_cac_check()

```
bool rx_cac_check (
    uint32_t * out_count)
```

Check the CAC frequency-error flag and snapshot count (implementation).

Sample the CAC status and counter buffer, clearing acknowledged flags.

Reads CASTR (status), latches the current CACNTBR (counter buffer) value if `out_count` is non-NULL, then issues a write-1-clear to the IRQ status flags in CAICR (preserving the IRQ enables). Returns whether the FERRF (frequency-error) flag was set since the last check.

Note

Safe from any context including ISR (single register read + write, no blocking).

Definition at line 314 of file [rx_cac.c](#).

```

00315 {
00316     if (!s_initialized) {
00317         return false;
00318     }
00319     volatile rx_cac_regs_t* regs = cac();
00320     uint8_t status = regs->castr;
00321     if (out_count != nullptr) {
00322         *out_count = (uint32_t)regs->cacntbr;
00323     }
00324     /* Preserve enabled IRQ settings while issuing write-1-clear acknowledgements. */
00325     uint8_t ack =
00326         (uint8_t)(regs->caicr & (uint8_t)(k_cac_caicr_ferrie_mask | k_cac_caicr_mendie_mask |
00327             k_cac_caicr_ovfie_mask));
00328     ack |= k_cac_caicr_clear_all_flags;
00329     regs->caicr = ack;
00330     return (bool)((status & k_cac_castr_ferrf_mask) != 0U);
00331 }

```

Here is the call graph for this function:

8.109.2.5 rx`cac`deinit()

```

rx_err_t rx_cac_deinit (
    void ) [nodiscard]

```

Fully deinitialize the CAC peripheral (implementation).

Tear down the CAC module and put it back in module-stop.

Stops the measurement (CFME=0), clears CACR1 / CACR2 (resetting the reference clock and tolerance), clears all IRQ flags via CAICR, then gates the CAC module clock through [internal_module_stop\(\)](#). Marks the driver as uninitialized.

Note

Not thread-safe. Serialize all `rx_cac_*` operations.

Definition at line 344 of file [rx_cac.c](#).

```

00345 {
00346     if (!s_initialized) {
00347         rx_log_error(s_tag, "rx_cac_deinit: not initialized");
00348         return k_rx_err_not_initialized;
00349     }
00350     volatile rx_cac_regs_t* regs = cac();
00351     regs->cacr0 = k_cac_cacr0_cfme_stop;
00352     regs->cacr1 = 0U;
00353     regs->cacr2 = 0U;
00354     regs->caicr = k_cac_caicr_clear_all_flags;
00355     internal_module_stop();
00356     s_initialized = false;
00357     return k_rx_ok;
00358 }

```

Here is the call graph for this function:

8.109.2.6 rx_cac_init()

```

rx_err_t rx_cac_init (
    const rx_cac_config_t * config)  [nodiscard]
  
```

Initialize the CAC module with the supplied configuration.

Performs the full CAC bring-up sequence mandated by the RX72N HW Manual Ch10.3 "Operation":

1. Unlock PRCR.PRC1 and clear MSTPCRC.MSTPC19, then re-lock PRCR.
2. With CACR0.CFME = 0, program CACR1 (FMCS, TCSS, EDGES, CAIE), CACR2 (RSCS, RCDS, RPS, DFS), CAULVR, CALLVR, and CAICR enables.
3. Clear any stale CASTR flags via CAICR write-1-clear.
4. Leave CFME = 0 (caller must invoke `rx_cac_start()` to begin measuring).

Parameters

in	config	Pointer to configuration struct (must not be nullptr)
----	--------	---

Returns

rx_err_t Error code

Return values

k_rx_ok	Initialization succeeded, CAC ready
k_rx_err_null_ptr	config is nullptr
k_rx_err_invalid_arg	Invalid clock/divider, or callvr >= caulvr
k_rx_err_invalid_state	CAC already initialized (call deinit first)

Precondition

```

config != nullptr
config->callvr < config->caulvr
config->reference_clock is in [k_cac_clock_main .. k_cac_clock_iwdtclk]
config->measured_clock is in [k_cac_clock_main .. k_cac_clock_clkout25]
config->target_div is in [k_cac_target_div_1 .. k_cac_target_div_32]
config->reference_div is in [k_cac_ref_div_32 .. k_cac_ref_div_8192]
  
```

Postcondition

CAC module is powered on (MSTPCRC.MSTPC19 = 0)
CACR0.CFME = 0 (measurement not yet running)
All configured limits and interrupt enables are loaded

Note

Not thread-safe. Call only during single-threaded initialization.

Since

Version 1.0.0

Definition at line 225 of file [rx_cac.c](#).

Here is the call graph for this function:

8.109.2.7 rx_cac_start()

```
rx_err_t rx_cac_start (
    void ) [nodiscard]
```

Start the CAC measurement (implementation).

Begin CAC measurement (CACR0.CFME = 1).

Sets CACR0.CFME=1 to enable comparison of the measurement clock against the reference clock configured by [rx_cac_init\(\)](#). Subsequent calls to [rx_cac_check\(\)](#) will report whether the measurement is within the configured tolerance window and return the latched count.

Note

Not thread-safe. Serialize all rx_cac_* operations.

Definition at line 271 of file [rx_cac.c](#).

```
00272 {
00273     if (!s_initialized) {
00274         rx_log_error(s_tag, "rx_cac_start: not initialized");
00275         return k_rx_err_not_initialized;
00276     }
00277     cac()->cacr0 = k_cac_cacr0_cfme_start;
00278     return k_rx_ok;
00279 }
```

References [cac\(\)](#), [rx_cac_regs_t::cacr0](#), [k_cac_cacr0_cfme_start](#), [s_initialized](#), and [s_tag](#).

Here is the call graph for this function:

8.109.2.8 rx_cac_stop()

```
rx_err_t rx_cac_stop (
    void ) [nodiscard]
```

Pause the CAC measurement (implementation).

Stop CAC measurement (CACR0.CFME = 0).

Clears CACR0.CFME, halting the measurement counter. The measurement configuration (reference clock, tolerance, IRQ enables) is preserved so a subsequent [rx_cac_start\(\)](#) resumes from a clean state. Useful when entering low-power modes or when switching reference clocks.

Note

Not thread-safe. Serialize all rx_cac_* operations.

Definition at line 292 of file [rx_cac.c](#).

```
00293 {
00294     if (!s_initialized) {
00295         rx_log_error(s_tag, "rx_cac_stop: not initialized");
00296         return k_rx_err_not_initialized;
00297     }
00298     cac()->cacr0 = k_cac_cacr0_cfme_stop;
00299     return k_rx_ok;
00300 }
```

Data Structures

- struct [rx_cmt_interrupt_config_t](#)
CMT interrupt routing and priority configuration.

Enumerations

- enum [cmt_constants_t](#) : `uint8_t` {
`k_cmt_max_channels = 4` , `k_cmt_divider_start = 0` , `k_cmt_div_8 = 0` , `k_cmt_div_32 = 1`
, `k_cmt_div_128 = 2` , `k_cmt_div_512 = 3` , `k_cmt_num_dividers = 4` }
CMT channel and divider configuration constants.

- enum `cmt_divider_values_t` : `uint16_t` { `k_cmt_divider_val_8` = 8 , `k_cmt_divider_val_32` = 32 , `k_cmt_divider_val_128` = 128 , `k_cmt_divider_val_512` = 512 }
CMT divider values (actual divisor values).
- enum `cmt_module_stop_bits_t` : `uint8_t` { `k_cmt_mstpa_unit0` = 15 , `k_cmt_mstpa_unit1` = 14 }
CMT module stop bit positions in MSTPCRA (RX72N Manual Section 11.2.2, p.406).
- enum `cmt_cmcr_bits_t` : `uint8_t` { `k_cmt_cmcr_cks_shift` = 0 , `k_cmt_cmcr_cmie_pos` = 6 , `k_cmt_cmcr_rsvd7_pos` = 7 }
CMCR register bit positions (RX72N Manual Ch31, p.1583).
- enum `cmt_period_constants_t` : `uint16_t` { `k_cmt_period_min` = 0 , `k_cmt_period_max` = 0xFFFF , `k_cmt_period_adj` = 1 }
Period calculation constants.
- enum `cmt_cmstr_bits_t` : `uint8_t` { `k_cmt_cmstr_str0` = 0 , `k_cmt_cmstr_str1` = 1 }
CMSTR register bit positions.
- enum `cmt_bit_constants_t` : `uint8_t` { `k_cmt_bit_mask_lsb` = 1 , `k_cmt_value_zero` = 0 }
CMT bit manipulation constants.

Functions

- void `cmt1_isr` (void)
CMT1 (CMT channel 1) compare-match interrupt service routine.
- void `cmt2_isr` (void)
CMT2 (CMT channel 2) compare-match interrupt service routine.
- void `cmt3_isr` (void)
CMT3 (CMT channel 3) compare-match interrupt service routine.
- static volatile `rx_cmt_channel_regs_t` * `internal_get_cmt_base` (const `rx_cmt_channel_t` channel)
Map a CMT channel enum to its hardware register base pointer.
- static `rx_err_t` `internal_calculate_cmt_params` (const `uint32_t` frequency_hz, `uint8_t` *divider, `uint16_t` *cmcor)
Calculate the optimal CMT clock divider and compare-match value for a target frequency.
- static void `internal_enable_cmt_module_clock` (void)
Enable the CMT module clock by clearing the MSTPCRB module-stop bit.
- static void `internal_configure_cmt_timer_registers` (volatile `rx_cmt_channel_regs_t` *cmt, const `uint8_t` divider, const `uint16_t` cmcor)
Write clock divider, interrupt-enable, compare-match, and counter registers.
- static `rx_err_t` `internal_configure_cmt_interrupt` (const `rx_cmt_interrupt_config_t` config)
Configure the ICU interrupt vector priority and enable for a CMT channel.
- static `rx_err_t` `internal_validate_cmt_init_params` (const `rx_cmt_channel_t` channel, const `rx_cmt_config_t` *config)
Validate channel and configuration pointer before CMT initialisation.
- static void `internal_save_cmt_callback` (const `rx_cmt_channel_t` channel, const `rx_cmt_config_t` *config)
Persist the user callback, user-data pointer, and channel initialized flag.
- `rx_err_t` `rx_cmt_init` (const `rx_cmt_channel_t` channel, const `rx_cmt_config_t` *config)
Initialize a CMT channel for periodic interrupt generation.
- `rx_err_t` `rx_cmt_start` (const `rx_cmt_channel_t` channel)
Start CMT counter for a previously initialized channel.
- `rx_err_t` `rx_cmt_stop` (const `rx_cmt_channel_t` channel)
Stop CMT counter without deinitializing the channel.
- `rx_err_t` `rx_cmt_get_count` (const `rx_cmt_channel_t` channel, `uint16_t` *count)
Read current CMT counter (CMCNT) value.
- `rx_err_t` `rx_cmt_deinit` (const `rx_cmt_channel_t` channel)
Deinitialize CMT channel and release all resources.

Variables

- static const char *const `s_tag` = "CMT"
- static bool `s_cmt_initialized` [`k_cmt_max_channels`] = {false}
Per-channel initialization status flags.
- static `rx_cmt_callback_t` `s_cmt_callback` [`k_cmt_max_channels`] = {nullptr}
Per-channel interrupt callback function pointers.
- static void * `s_cmt_user_data` [`k_cmt_max_channels`] = {nullptr}
Per-channel user data for callbacks.

8.111.1 Detailed Description

CMT (Compare Match Timer) Driver Implementation - Periodic Interrupt Generation.

8.111.2 Overview

Implements the CMT driver for periodic interrupt generation on the RX72N. This file contains all internal helpers, interrupt handlers, and the public API implementation for CMT channels 0-3.

8.111.2.1 Implementation Architecture

8.111.2.2 CMT Timer Operation

The CMT operates as a 16-bit up-counter with compare match:

8.111.2.3 Clock Divider Selection Algorithm

The driver tries each divider in order ($/8$, $/32$, $/128$, $/512$) and selects the first one that produces a period fitting in 16 bits:

```

period = (PCLKB / divider) / frequency
if (0 < period <= 65535): use this divider
  
```

Divider	PCLKB/div	Min Period	Max Period
$/\leftarrow 8$	7.5 MHz	1 (7.5 MHz)	65535 (115 Hz)
$/32$	1.875 MHz	1 (1.875 MHz)	65535 (29 Hz)
$/128$	468.75 kHz	1 (469 kHz)	65535 (7.2 Hz)
$/512$	117.2 kHz	1 (117 kHz)	65535 (1.8 Hz)

8.111.2.4 Memory Map (Static State)

Symbol	Size	Description
<code>s_cmt_$\leftarrow$initialized[]</code>	4 bytes	Per-channel init flags
<code>s_cmt_$\leftarrow$callback[]</code>	16 bytes	Callback function pointers
<code>s_cmt_user_$\leftarrow$data[]</code>	16 bytes	User data pointers

Total static allocation: 36 bytes

8.111.2.5 Register Access Pattern

All register access uses inline accessor functions for type safety:

- [cmt0\(\)](#), [cmt1\(\)](#), [cmt2\(\)](#), [cmt3\(\)](#) - Channel registers
- [cmt_ctrl\(\)](#) - Control registers (CMSTR0, CMSTR1)
- [icu\(\)](#) - Interrupt controller

8.111.2.6 NASA Power of 10 Compliance

Rule	Implementation
Rule 1	No goto/recursion, single return paths
Rule 2	Bounded loop in internal_calculate_cmt_params()
Rule 3	Static arrays only, no heap
Rule 4	All functions under 60 lines
Rule 5	Parameter validation in all public functions
Rule 6	File-scope static with s_ prefix
Rule 7	All return values checked
Rule 8	C23 typed enums for all constants
Rule 9	Single-level pointers only
Rule 10	Clean with -Wall -Wextra -Werror

8.111.3 Data Structure Documentation

8.111.3.1 struct rx`cmt`interrupt`config`

CMT interrupt routing and priority configuration.

Bundles the CMT channel identifier with the desired ICU interrupt priority level. Passed by value to [internal_configure_cmt_interrupt\(\)](#) so that the caller does not need to keep the structure alive after the call returns.

The channel field selects which ICU interrupt vector to program (CMI0-CMI3), and the priority field is written directly into the corresponding IPR[] register.

Invariant

- channel must be a valid [rx_cmt_channel_t](#) value (0-3)
- priority must be in [k_ipr_level_min, k_ipr_level_max]

Example:

```
rx_cmt_interrupt_config_t irq_cfg = {  
    .channel = k_cmt_channel_1,  
    .priority = 5,  
};  
rx_err_t err = internal_configure_cmt_interrupt(irq_cfg);
```

Collaboration diagram for rx_cmt_interrupt_config_t:

Data Fields

rx_cmt_channel_t	channel	CMT channel identifier (k_cmt_channel_0 ... k_cmt_channel_3)
uint8_t	priority	ICU interrupt priority level (k_ipr_level_min ... k_ipr_level_max)

8.111.4 Enumeration Type Documentation

8.111.4.1 cmt_bit_constants_t

enum [cmt_bit_constants_t](#) : uint8_t

CMT bit manipulation constants.

Enumerator

k_cmt_bit_mask_lsb	Single bit set for shifts
k_cmt_value_zero	Zero value for comparisons

Definition at line 271 of file [rx_cmt.c](#).

```
00271      : uint8_t {
00272  k_cmt_bit_mask_lsb = 1, /**< Single bit set for shifts */
00273  k_cmt_value_zero   = 0, /**< Zero value for comparisons */
00274 } cmt_bit_constants_t;
```

8.111.4.2 cmt_cmcr_bits_t

enum [cmt_cmcr_bits_t](#) : uint8_t

CMCR register bit positions (RX72N Manual Ch31, p.1583).

Enumerator

k_cmt_cmcr_cks_shift	CKS (clock select) bit shift
k_cmt_cmcr_cmie_pos	CMIE (interrupt enable) bit position
k_cmt_cmcr_rsvd7_pos	Reserved bit 7: write value should be 1

Definition at line 251 of file [rx_cmt.c](#).

```
00251      : uint8_t {
00252  k_cmt_cmcr_cks_shift = 0, /**< CKS (clock select) bit shift */
00253  k_cmt_cmcr_cmie_pos  = 6, /**< CMIE (interrupt enable) bit position */
00254  k_cmt_cmcr_rsvd7_pos = 7, /**< Reserved bit 7: write value should be 1 */
00255 } cmt_cmcr_bits_t;
```

8.111.4.3 cmt`cmstr`bits``t`

```
enum cmt\_cmstr\_bits\_t : uint8_t
```

CMSTR register bit positions.

Enumerator

<code>k_cmt_cmstr_str0</code>	CMT0/CMT2 start bit
<code>k_cmt_cmstr_str1</code>	CMT1/CMT3 start bit

Definition at line [265](#) of file [rx_cmt.c](#).

```
00265     : uint8_t {
00266     k_cmt_cmstr_str0 = 0, /**< CMT0/CMT2 start bit */
00267     k_cmt_cmstr_str1 = 1, /**< CMT1/CMT3 start bit */
00268 } cmt_cmstr_bits_t;
```

8.111.4.4 cmt`constants``t`

```
enum cmt\_constants\_t : uint8_t
```

CMT channel and divider configuration constants.

Defines the channel count, divider settings, and loop bounds for CMT configuration. These values correspond to RX72N hardware capabilities.

8.111.4.5 Divider Settings (CMCR.CKS field)

CKS Value	Divider	Counter Clock @60MHz
0b00	$\frac{1}{8}$	7.5 MHz
0b01	$\frac{1}{32}$	1.875 MHz
0b10	$\frac{1}{128}$	468.75 kHz
0b11	$\frac{1}{512}$	117.19 kHz

Note

`k_cmt_divider_start` and `k_cmt_num_dividers` define loop bounds for NASA Power of 10 Rule 2 compliance.

Since

Version 1.0.0

Enumerator

<code>k_cmt_max_channels</code>	Total CMT channels: CMT0, CMT1, CMT2, CMT3
---------------------------------	--

00262 } cmt_period_constants_t;
```

8.111.5 Function Documentation

8.111.5.1 cmt1_isr()

```
void cmt1_isr (
    void )
```

CMT1 (CMT channel 1) compare-match interrupt service routine.

Invoked by the RX72N hardware whenever the CMT1 counter (CMCNT) reaches the value stored in CMCOR. The ISR checks whether a callback has been registered in `s_cmt_callback[k_cmt_channel_1]` and, if so, calls it with the associated user data pointer from `s_cmt_user_data[k_cmt_channel_1]`.

The compare-match interrupt flag is automatically cleared by the RX72N hardware upon entry; no explicit IR register write is needed.

Note

Executes in interrupt context; all code in this ISR and any registered callback must be ISR-safe (no blocking, no long operations)

Not thread-safe; the callback executes with the CMT1 interrupt masked

Warning

Do not call any ThreadX API that is not interrupt-safe from the registered callback (e.g., `tx_thread_sleep()` is forbidden; use ISR-safe variants such as `tx_semaphore_put_from_isr()`)

See also

8.111.5.2 cmt2_isr()

```
void cmt2_isr (
    void )
```

CMT2 (CMT channel 2) compare-match interrupt service routine.

Invoked by the RX72N hardware whenever the CMT2 counter (CMCNT) reaches the value stored in CMCOR. The ISR checks whether a callback has been registered in `s_cmt_callback[k_cmt_channel_2]` and, if so, calls it with the associated user data pointer from `s_cmt_user_data[k_cmt_channel_2]`.

The compare-match interrupt flag is automatically cleared by the RX72N hardware upon entry; no explicit IR register write is needed.

Note

Executes in interrupt context; all code in this ISR and any registered callback must be ISR-safe (no blocking, no long operations)

Not thread-safe; the callback executes with the CMT2 interrupt masked

Warning

Do not call any ThreadX API that is not interrupt-safe from the registered callback (e.g., `tx_thread_sleep()` is forbidden; use ISR-safe variants such as `tx_semaphore_put_from_isr()`)

See also

8.111.5.3 cmt3_isr()

```
void cmt3_isr (
    void )
```

CMT3 (CMT channel 3) compare-match interrupt service routine.

Invoked by the RX72N hardware whenever the CMT3 counter (CMCNT) reaches the value stored in CMCOR. The ISR checks whether a callback has been registered in [s_cmt_callback\[k_cmt_channel_3\]](#) and, if so, calls it with the associated user data pointer from [s_cmt_user_data\[k_cmt_channel_3\]](#).

The compare-match interrupt flag is automatically cleared by the RX72N hardware upon entry; no explicit IR register write is needed.

Note

Executes in interrupt context; all code in this ISR and any registered callback must be ISR-safe (no blocking, no long operations)

Not thread-safe; the callback executes with the CMT3 interrupt masked

Warning

Do not call any ThreadX API that is not interrupt-safe from the registered callback (e.g., [tx_thread_sleep\(\)](#) is forbidden; use ISR-safe variants such as [tx_semaphore_put_from_isr\(\)](#))

See also

8.111.5.4 internal'calculate'cmt'params()

```
rx_err_t internal_calculate_cmt_params (
    const uint32_t frequency_hz,
    uint8_t * divider,
    uint16_t * cmcor) [static]
```

Calculate the optimal CMT clock divider and compare-match value for a target frequency.

Iterates the four available PCLKB clock dividers (/8, /32, /128, /512) in ascending order and selects the first divider whose resulting 16-bit period value satisfies:

```
period = (PCLKB / divider) / frequency_hz
0 < period <= 65535
```

The chosen divider index is returned in *divider (corresponding to the CKS field of CMCR: 0=/8, 1=/32, 2=/128, 3=/512). The compare-match register value is returned in *cmcor; the caller must subtract the adjustment constant k_cmt_period_adj when writing to the hardware register.

Algorithm steps:

1. Validate output pointers are non-null
2. Reject frequency_hz == 0 or frequency_hz > PCLKB/8 (maximum achievable)
3. Loop i from k_cmt_divider_start to k_cmt_num_dividers - 1
4. Compute period_calc = (PCLKB / dividers[i]) / frequency_hz
5. If 0 < period_calc <= 65535, store i and period_calc, return k_rx_ok
6. If no divider fits, return k_rx_err_invalid_arg

Precondition

divider must point to a valid uint8_t storage location
cmcor must point to a valid uint16_t storage location

Postcondition

On k_rx_ok: *divider holds the CKS value (0-3) for CMCR
On k_rx_ok: *cmcor holds the period count; caller subtracts 1 before writing CMCR

Note

Not thread-safe; pure computation with no shared state modification
Uses a bounded loop (k_cmt_num_dividers iterations) – NASA Rule 2 compliant

Thread Safety:

Pure computation with no global or static state; safe to call from any context.

Performance:

Execution time: ~5 cycles (loop unrolled at -O2 for 4 divider steps)

Example:

```
uint8_t divider = 0;
uint16_t cmcor = 0;
rx_err_t err = internal_calculate_cmt_params(1000U, &divider, &cmcor);
if (err == k_rx_ok) {
    // divider and cmcor are ready for use in CMCR/CMCOR registers
}
```

Here is the caller graph for this function:

8.111.5.5 internal_configure_cmt_interrupt()

```
rx_err_t internal_configure_cmt_interrupt (
    const rx_cmt_interrupt_config_t config) [static]
```

Configure the ICU interrupt vector priority and enable for a CMT channel.

Programs the Interrupt Controller Unit (ICU) to route and enable the compare-match interrupt (CMI_n) for the specified CMT channel. The three ICU registers modified are:

1. IPR[vector] - Sets the interrupt priority level for the channel's CMI_n vector to config.priority.
2. IER[index] - Sets the enable bit for the channel's interrupt vector within the IER register array. The bit index and byte index are derived from the vector number.
3. IR[vector] - Clears any pending interrupt flag before enabling, so a stale flag does not fire immediately after enable.

The vector number is computed as `k_vect_cmt0_cmi0 + config.channel`, which yields CMI₀ for channel 0, CMI₁ for channel 1, and so on.

Precondition

config.channel must be in the range [0, k_cmt_max_channels)
 config.priority must be in [k_ipr_level_min, k_ipr_level_max]

Postcondition

ICU IPR register for the channel's vector set to config.priority
 ICU IER bit for the channel's vector enabled
 ICU IR flag for the channel's vector cleared

Note

Not thread-safe; concurrent ICU modification from another context is unsafe
 Clears IR before enabling to prevent a spurious first interrupt

Thread Safety:

Not thread-safe. Must be called during initialization with interrupts disabled or before the RTOS scheduler starts.

Performance:

Execution time: ~4 register accesses; negligible overhead

Example:

```
rx_cmt_interrupt_config_t irq_cfg = {
    .channel = k_cmt_channel_1,
    .priority = 5,
};
rx_err_t err = internal_configure_cmt_interrupt(irq_cfg);
if (err != k_rx_ok) {
    return err;
}
```

Here is the call graph for this function:

Here is the caller graph for this function:

8.111.5.6 internal_configure_cmt_timer_registers()

```
void internal_configure_cmt_timer_registers (  
    volatile rx_cmt_channel_regs_t * cmt,  
    const uint8_t divider,  
    const uint16_t cmcor)    [static]
```

Write clock divider, interrupt-enable, compare-match, and counter registers.

Programs the three CMT hardware registers for a single channel in the following order:

1. CMCOR - Sets the CKS (clock-select) field from divider and enables the compare-match interrupt (CMIE bit).
2. CMCOR - Loads the compare-match value after subtracting the adjustment constant `k_cmt_period_adj` (-1) so the hardware fires at the correct period.
3. CMCNT - Clears the counter to 0 so the first interrupt occurs exactly one full period after the timer is started.

The timer must be stopped (CMSTR bit cleared) before calling this function to avoid race conditions while writing to CMCOR and CMCNT.

Precondition

`cmt` must not be nullptr (enforced by `RX_ASSERT`)

The CMT timer must be stopped before calling this function

Postcondition

`cmt->cmcr` = (divider << CKS_SHIFT) | CMIE_BIT | RSVD7_BIT (bit7 must be written 1)

`cmt->cmcor` = `cmcor` - `k_cmt_period_adj`

`cmt->cmcnt` = 0

Note

Not thread-safe; caller must ensure the timer is stopped

`RX_ASSERT` fires in debug builds if `cmt` is nullptr

Thread Safety:

Not thread-safe. Must be called with the timer stopped and no concurrent ISR activity on this channel.

Performance:

Execution time: ~3 register writes; negligible overhead

Example:

```
uint8_t divider = 0;
uint16_t cmcor = 0;
(void)internal_calculate_cmt_params(1000U, &divider, &cmcor);
volatile rx_cmt_channel_regs_t* cmt = internal_get_cmt_base(k_cmt_channel_1);
internal_configure_cmt_timer_registers(cmt, divider, cmcor);
```

```
00605 {
00606   RX_ASSERT(cmt != nullptr, "CMT registers are NULL");
00607
00608   /* Configure timer control register
00609    * - Set clock divider (bits 1-0)
00610    * - Enable compare match interrupt (bit 6)
00611    * - Set reserved bit 7 to 1 (write value should be 1 per RX72N manual p.1583)
00612    */
00613   cmt->cmcr =
00614     (divider « k_cmt_cmcr_cks_shift) | /* CKS: Clock Select */
00615     (k_cmt_bit_mask_lsb « k_cmt_cmcr_cmie_pos) | /* CMIE: Compare Match Interrupt Enable */
00616     (k_cmt_bit_mask_lsb « k_cmt_cmcr_rsvd7_pos); /* Reserved bit 7: write value should be 1 */
00617
00618   /* Set compare match value (period - 1) */
00619   cmt->cmcor = cmcor - k_cmt_period_adj;
00620
00621   /* Clear counter */
00622   cmt->cmcnt = k_cmt_value_zero;
00623 }
```

References [rx_cmt_channel_regs_t::cmcnt](#), [rx_cmt_channel_regs_t::cmcor](#), [rx_cmt_channel_regs_t::cmcr](#), [k_cmt_bit_mask_lsb](#), [k_cmt_cmcr_cks_shift](#), [k_cmt_cmcr_cmie_pos](#), [k_cmt_cmcr_rsvd7_pos](#), [k_cmt_period_adj](#), and [k_cmt_value_zero](#).

Referenced by [rx_cmt_init\(\)](#).

Here is the caller graph for this function:

8.111.5.7 internal`enable`cmt`module`clock()

```
void internal_enable_cmt_module_clock (
    void ) [static]
```

Enable the CMT module clock by clearing the MSTPCRB module-stop bit.

Removes the CMT0-CMT3 peripheral from module-stop state so that the module clock is supplied and its registers become accessible. The sequence is:

1. Unlock the write-protect register (PRCR) for PRC1 and PRC3 bits
2. Clear bit `k_cmt_mstpa_unit0` (bit 15) in `MSTPCRA` to enable CMT unit 0 (CMT0/CMT1)
3. Clear bit `k_cmt_mstpa_unit1` (bit 14) in `MSTPCRA` to enable CMT unit 1 (CMT2/CMT3)
4. Re-lock the PRCR to prevent accidental modification

This function must be called before any CMT register access; reading or writing CMT registers while the module clock is stopped produces undefined hardware behaviour on the RX72N.

The function is idempotent: calling it when the module is already enabled simply clears an already-clear bit, which is harmless.

Precondition

The system clock (PCLKB) must be running before calling this function
No other task or ISR must be concurrently modifying `MSTPCRB`

Postcondition

`MSTPCRA` bits 15 and 14 are cleared; CMT module clocks for all 4 channels are active
PRCR is locked upon return (prevents accidental `MSTPCRB` changes)

Note

Not thread-safe; PRCR unlock/lock is a non-atomic read-modify-write
Called once per system lifetime; subsequent calls are benign

Thread Safety:

Not thread-safe. Call during system initialization before RTOS scheduler starts, or with interrupts disabled.

Performance:

Execution time: ~4 register writes; negligible overhead

Example:

```
// Called internally by rx_cmt_init(); not intended for direct use
internal_enable_cmt_module_clock();
// CMT registers are now accessible
```

Here is the call graph for this function:

Here is the caller graph for this function:

8.111.5.8 internal`get`cmt`base()

```
volatile rx_cmt_channel_regs_t * internal_get_cmt_base (
    const rx_cmt_channel_t channel) [static]
```

Map a CMT channel enum to its hardware register base pointer.

Uses a switch statement to convert a logical channel identifier into a pointer to the corresponding volatile [rx_cmt_channel_regs_t](#) register block. The four CMT channels (CMT0-CMT3) each have a distinct base address in the RX72N memory map; the inline accessor functions [cmt0\(\)](#)-[cmt3\(\)](#) encode those addresses in a type-safe manner.

The default case returns nullptr, which every caller is expected to check immediately after the call (NASA Rule 7 compliance).

Precondition

channel is a member of [rx_cmt_channel_t](#) (0-3)

Hardware register addresses must be accessible (clocks enabled before use)

Postcondition

Return value, if non-null, points to the live hardware register block
 Caller must validate the return value before dereferencing (Rule 7)

Note

Not thread-safe; the hardware registers are globally shared
 This function never writes to hardware; it only computes an address

Thread Safety:

Read-only address computation; no shared mutable state is accessed.

Performance:

Execution time: ~1 cycle (single branch/address load with -O2)

Example:

```
volatile rx_cmt_channel_regs_t* cmt = internal_get_cmt_base(k_cmt_channel_2);
if (cmt == nullptr) {
    return k_rx_err_invalid_arg;
}
cmt->cmcnt = 0;
```

Here is the call graph for this function:

Here is the caller graph for this function:

8.111.5.9 internal_save_cmt_callback()

```

void internal_save_cmt_callback (
    const rx_cmt_channel_t channel,
    const rx_cmt_config_t * config) [static]
  
```

Persist the user callback, user-data pointer, and channel initialized flag.

Copies the callback function pointer and user-data pointer from the caller's configuration structure into the module-level static arrays, then marks the channel as initialized. After this call the ISR for the channel will invoke the registered callback on every compare-match event.

This function is the final step in the `rx_cmt_init()` sequence. It must only be called after all hardware registers have been programmed and the interrupt has been configured in the ICU, so that the ISR never encounters a partially initialised channel state.

Precondition

channel must be valid and in range [1, k_cmt_max_channels) (validated by caller)
 config must be non-null (validated by `internal_validate_cmt_init_params`)

Postcondition

```

s_cmt_callback[channel] = config->callback
s_cmt_user_data[channel] = config->user_data
s_cmt_initialized[channel] = true
  
```

Note

Not thread-safe; must be the last step of `rx_cmt_init()` with interrupts either disabled or not yet fired for this channel

After this call the channel is considered "live"; the ISR may fire at any point

Thread Safety:

Not thread-safe. The three static array writes are not atomic. Call only during initialization with the channel interrupt not yet active.

Performance:

Execution time: ~3 stores; negligible overhead

Example:

```
// Final step inside rx_cmt_init() after all hardware setup is complete
internal_save_cmt_callback(channel, config);
// s_cmt_initialized[channel] is now true; ISR will call config->callback
```

Here is the caller graph for this function:

8.111.5.10 internal_validate_cmt_init_params()

```
rx_err_t internal_validate_cmt_init_params (
    const rx_cmt_channel_t channel,
    const rx_cmt_config_t * config) [static]
```

Validate channel and configuration pointer before CMT initialisation.

Performs all parameter checking required before `rx_cmt_init()` proceeds to hardware configuration. Validation is performed in this strict order:

1. Verify config pointer is non-null (`k_rx_err_null_ptr`)
2. Verify channel is within `[0, k_cmt_max_channels)` (`k_rx_err_invalid_arg`)
3. Reject channel 0, which is reserved for the ThreadX system-tick timer (`k_rx_err_conflict`)
4. Verify interrupt priority is within `[k_ipr_level_min, k_ipr_level_max]` (`k_rx_err_invalid_arg`)

Centralising these checks in a dedicated helper keeps the main `rx_cmt_init()` function concise and ensures that every check is logged before returning.

Precondition

config must be a pointer to a caller-owned `rx_cmt_config_t` (may be nullptr)
channel must be a member of `rx_cmt_channel_t`

Postcondition

On `k_rx_ok`: channel and `*config` are safe to use for hardware programming
On error: an error message has been emitted via `rx_log_error()`

Note

Not thread-safe; pure validation with no shared state modification

The lower-bound check `channel >= k_cmt_channel_0` is intentionally omitted to avoid -Wtype-limits: channel is `uint8_t` and `k_cmt_channel_0 == 0`, making the comparison always true

Thread Safety:

Pure validation; no shared mutable state is modified. Safe to call from any context, but the result may be stale if state changes after the call.

Performance:

Execution time: ~ 4 comparisons; negligible overhead

Example:

```
rx_err_t err = internal_validate_cmt_init_params(k_cmt_channel_1, &config);
if (err != k_rx_ok) {
    return err;
}
```

Here is the caller graph for this function:

8.111.5.11 rx_cmt_deinit()

```
rx_err_t rx_cmt_deinit (
    const rx_cmt_channel_t channel) [nodiscard]
```

Deinitialize CMT channel and release all resources.

Deinitialize CMT channel.

Stops the CMT counter, disables the ICU interrupt for the channel, clears the stored callback and user data, and marks the channel as uninitialized. After this call the channel may be re-initialized with [rx_cmt_init\(\)](#).

Algorithm steps:

1. Validate channel range
2. Stop timer via [rx_cmt_stop\(\)](#) and propagate any error
3. Compute ICU vector, IER index, and IER bit for the channel
4. Clear the IER bit to disable the interrupt
5. Clear callback, user_data, and initialized flag

Precondition

channel must be in range [0, 3]

Caller should ensure no other task is using the channel callback

Postcondition

Counter halted (CMSTR bit cleared)

ICU interrupt disabled for channel

s_cmt_initialized[channel] set to false

s_cmt_callback[channel] and s_cmt_user_data[channel] set to nullptr

Note

Safe to call on an uninitialized channel ([rx_cmt_stop](#) tolerates it)

Module clock is NOT re-asserted - hardware remains clocked for re-use

Thread Safety:

Not thread-safe. Ensure no ISR or other thread is using the channel.

Example:

```
rx_err_t err = rx_cmt_deinit(k_cmt_channel_1);
if (err != k_rx_ok) {
    rx_log_error("APP", "CMT deinit failed");
}
```

Here is the call graph for this function:

8.111.5.12 rx_cmt_get_count()

```

rx_err_t rx_cmt_get_count (
    const rx_cmt_channel_t channel,
    uint16_t * count) [nodiscard]

```

Read current CMT counter (CMCNT) value.

Get CMT counter value.

Returns the instantaneous value of the 16-bit CMCNT register for the specified channel. The counter increments at PCLKB divided by the configured divider (/8, /32, /128, or /512) and resets to 0 on compare match. Useful for measuring elapsed time within a period.

Precondition

Channel must be initialized via [rx_cmt_init\(\)](#)
 count must point to valid uint16_t storage

Postcondition

*count set to CMCNT register value at time of read
 Counter continues running (read is non-destructive)

Note

Value may change between consecutive reads if counter is running
 For precise time measurements disable interrupts around consecutive reads

Thread Safety:

Read-only; safe to call from multiple contexts, but value may be stale.

Example:

```
uint16_t ticks = 0;
rx_err_t err = rx_cmt_get_count(k_cmt_channel_1, &ticks);
if (err == k_rx_ok) {
    // ticks = current counter position within the period
}
```

01336     cmt = internal_get_cmt_base(channel);
01337     if (cmt == nullptr) {
01338         return k_rx_err_invalid_arg;
01339     }
01340
01341     *count = cmt->cmcnt;
01342     return k_rx_ok;
01343 }
```

References [rx_cmt_channel_regs_t::cmcnt](#), [internal_get_cmt_base\(\)](#), [k_cmt_max_channels](#), [s_cmt_initialized](#), and [s_tag](#).

Here is the call graph for this function:

8.111.5.13 rx_cmt_init()

```

rx_err_t rx_cmt_init (
    const rx_cmt_channel_t channel,
    const rx_cmt_config_t * config) [nodiscard]

```

Initialize a CMT channel for periodic interrupt generation.

Initialize CMT channel for periodic interrupts.

Configures a CMT (Compare Match Timer) channel to fire a user callback at the requested frequency. Validates parameters, selects the optimal clock divider, enables the module clock, stops the timer for safe configuration, programs timer registers, configures the ICU interrupt routing, saves the callback, and starts the timer.

Algorithm steps:

1. Validate channel and config parameters via [internal_validate_cmt_init_params\(\)](#)
2. Obtain CMT channel register base via [internal_get_cmt_base\(\)](#)
3. Calculate optimal divider and CMCOR value via [internal_calculate_cmt_params\(\)](#)
4. Enable CMT module clock (clear MSTPCRB bit) via [internal_enable_cmt_module_clock\(\)](#)
5. Stop the timer to allow safe register writes via [rx_cmt_stop\(\)](#)
6. Program CMCR (divider + CMIE) and CMCOR via [internal_configure_cmt_timer_registers\(\)](#)
7. Configure ICU interrupt vector priority and enable via [internal_configure_cmt_interrupt\(\)](#)
8. Save callback pointer and mark channel initialized via [internal_save_cmt_callback\(\)](#)
9. Start the timer via [rx_cmt_start\(\)](#)

Clock divider selection: The driver iterates dividers /8, /32, /128, /512 and picks the first that produces a period fitting in 16 bits:

```

period = (PCLKB / divider) / frequency_hz
if (0 < period <= 65535): use this divider

```

Precondition

config must point to a valid `rx_cmt_config_t` structure
config->frequency_hz must be > 0 and $\leq \text{PCLKB} / 8$ (7.5 MHz at 60 MHz PCLKB)
channel must not be `k_cmt_channel_0`
System clocks must be initialized ($\text{PCLKB} = 60 \text{ MHz}$)

Postcondition

Timer running at requested frequency
config->callback registered and called from ISR at each compare match
`s_cmt_initialized[channel]` set to true
ICU interrupt for the channel enabled at specified priority

Note

Not thread-safe - call once per channel during system initialization
Callback executes in interrupt context; keep it short and non-blocking

Warning

CMT0 is reserved for ThreadX; do not use `k_cmt_channel_0`

Thread Safety:

Not thread-safe. Call once per channel during initialization before starting the RTOS scheduler or with interrupts disabled.

Performance:

- Execution time: $\sim 5 \text{ us}$ (mostly register writes)
- Stack usage: 48 bytes

Example:

```
static void my_timer_cb(void* user_data)
{
    // Called at 1 kHz from interrupt context
    (void)user_data;
    toggle_led();
}

const rx_cmt_config_t cfg = {
    .frequency_hz = 1000, // 1 kHz
    .priority     = 5,
    .callback     = my_timer_cb,
    .user_data    = nullptr,
};

rx_err_t err = rx_cmt_init(k_cmt_channel_1, &cfg);
if (err != k_rx_ok) {
    rx_log_error("APP", "CMT init failed");
}
```

Here is the call graph for this function:

8.111.5.14 rx'cmt'start()

```
rx_err_t rx_cmt_start (
    const rx_cmt_channel_t channel) [nodiscard]
```

Start CMT counter for a previously initialized channel.

Start CMT timer.

Sets the appropriate bit in the CMSTR0 or CMSTR1 register to start the CMT counter running. After setting the bit the register is read back to verify the hardware accepted the write. Channels 0/1 share CMSTR0; channels 2/3 share CMSTR1. Channels 0 and 1 use STR0/STR1 bits respectively, as do channels 2 and 3.

Precondition

- channel must be initialized via [rx_cmt_init\(\)](#)
- channel must be in range [0, 3]

Postcondition

CMSTR bit for channel is set
Counter begins incrementing from its current value

Note

Usually called automatically by `rx_cmt_init()`; call explicitly only after `rx_cmt_stop()`
Performs a readback check to verify the hardware write succeeded

Thread Safety:

Not thread-safe; do not call concurrently with stop/deinit on the same channel.

Example:

```
// Pause then resume timer
rx_cmt_stop(k_cmt_channel_1);
// ... do critical work ...
rx_cmt_start(k_cmt_channel_1);
```

8.111.5.15 rx`cmt`stop()

```

rx_err_t rx_cmt_stop (
    const rx_cmt_channel_t channel) [nodiscard]

```

Stop CMT counter without deinitializing the channel.

Stop CMT timer.

Clears the appropriate bit in CMSTR0 or CMSTR1 to halt the CMT counter. After clearing the bit the register is read back to verify the hardware accepted the write. The channel remains initialized; call [rx_cmt_start\(\)](#) to resume counting.

Note that [rx_cmt_stop\(\)](#) does NOT require the channel to be initialized (`s_cmt_initialized` check is omitted intentionally so that [rx_cmt_init\(\)](#) can call it safely before marking the channel as initialized).

Precondition

channel must be in range [0, 3]

Interrupts may still fire if one is already pending when stop is called

Postcondition

CMSTR bit for channel is cleared

Counter stops incrementing (current CMCNT value preserved)

Note

Does not clear the initialized flag - channel can be restarted

Called by `rx_cmt_init()` before programming registers (safe on uninitialized channel)

Thread Safety:

Not thread-safe; do not call concurrently with start/init/deinit on the same channel.

Example:

```
// Temporarily suspend timer
rx_cmt_stop(k_cmt_channel_2);
reconfigure_something();
rx_cmt_start(k_cmt_channel_2);
```

8.111.6 Variable Documentation

8.111.6.1 s`cmt`callback

[rx_cmt_callback_t](#) `s_cmt_callback[k_cmt_max_channels]` = {nullptr} [static]

Per-channel interrupt callback function pointers.

Stores user-provided callback functions for each CMT channel. Called from the corresponding interrupt handler (`cmt1_isr`, `cmt2_isr`, `cmt3_isr`).

Note

NULL callbacks are valid - interrupt fires but no action taken.

Warning

Callback executes in interrupt context. Keep it fast!

See also

[rx_cmt_callback_t](#) Callback function type

Since

Version 1.0.0

Definition at line 318 of file [rx_cmt.c](#).

```
00318 {nullptr};
```

Referenced by [cmt1_isr\(\)](#), [cmt2_isr\(\)](#), [cmt3_isr\(\)](#), [internal_save_cmt_callback\(\)](#), and [rx_cmt_deinit\(\)](#).

8.111.6.2 s'cmt'initialized

```
bool s_cmt_initialized[k\_cmt\_max\_channels] = {false} [static]
```

Per-channel initialization status flags.

Tracks whether each CMT channel has been initialized. Set to true after successful [rx_cmt_init\(\)](#), cleared on [rx_cmt_deinit\(\)](#).

Index	Channel	Initial Value
0	CMT0	false (ThreadX manages)
1	CMT1	false
2	CMT2	false
3	CMT3	false

Note

Used to prevent operations on uninitialized channels.

Warning

Do not modify directly; managed by init/deinit functions.

Since

Version 1.0.0

Definition at line 301 of file [rx_cmt.c](#).

```
00301 {false};
```

8.111.6.3 s_cmt_user_data

```
void* s_cmt_user_data[k_cmt_max_channels] = {nullptr} [static]
```

Per-channel user data for callbacks.

Stores user-provided context data passed to callbacks. Allows callbacks to access application-specific state without global variables.

Note

May be NULL if callback doesn't need user data.

00001 /**
00002  * @file rx_cmt.c
00003  * @brief CMT (Compare Match Timer) Driver Implementation - Periodic Interrupt Generation
00004  *
00005  * @details
00006  * # Overview
00007  *
00008  * Implements the CMT driver for periodic interrupt generation on the RX72N.
00009  * This file contains all internal helpers, interrupt handlers, and the public
00010  * API implementation for CMT channels 0-3.
00011  *
00012  * ## Implementation Architecture
00013  *
00014  * @dot
00015  * digraph implementation {
00016  *   rankdir=TB;
00017  *   node [shape=box, style=rounded];
00018  *
00019  *   subgraph cluster_public {
00020  *     label="Public API";
00021  *     style=filled;
00022  *     color=lightgreen;
00023  *     init [label="rx_cmt_init()"];
00024  *     start [label="rx_cmt_start()"];
00025  *     stop [label="rx_cmt_stop()"];
00026  *     count [label="rx_cmt_get_count()"];
00027  *     deinit [label="rx_cmt_deinit()"];
00028  *   }
00029  *
00030  *   subgraph cluster_internal {
00031  *     label="Internal Helpers";
00032  *     style=filled;
```

```

00033 *   color=lightyellow;
00034 *   get_base [label="internal_get_cmt_base()"];
00035 *   calc [label="internal_calculate_cmt_params()"];
00036 *   enable [label="internal_enable_cmt_module_clock()"];
00037 *   configure [label="internal_configure_cmt_timer_registers()"];
00038 *   irq [label="internal_configure_cmt_interrupt()"];
00039 *   validate [label="internal_validate_cmt_init_params()"];
00040 *   save [label="internal_save_cmt_callback()"];
00041 * }
00042 *
00043 * subgraph cluster_isr {
00044 *   label="Interrupt Handlers";
00045 *   style=filled;
00046 *   color=lightblue;
00047 *   cmt1_isr [label="cmt1_isr()"];
00048 *   cmt2_isr [label="cmt2_isr()"];
00049 *   cmt3_isr [label="cmt3_isr()"];
00050 * }
00051 *
00052 * init -> validate -> calc -> enable -> configure -> irq -> save;
00053 * init -> start;
00054 * start -> get_base;
00055 * stop -> get_base;
00056 * count -> get_base;
00057 * cmt1_isr -> s_cmt_callback [label="call"];
00058 * }
00059 * @enddot
00060 *
00061 * ## CMT Timer Operation
00062 *
00063 * The CMT operates as a 16-bit up-counter with compare match:
00064 *
00065 * @msc
00066 *   width=600;
00067 *   CMCNT, CMCOR, ISR, Callback;
00068 *
00069 *   CMCNT box CMCNT [label="Counter at 0"];
00070 *   CMCNT -> CMCNT [label="Count: 1, 2, 3..."];
00071 *   CMCNT => CMCOR [label="CMCNT reaches CMCOR"];
00072 *   CMCOR box CMCOR [label="Compare match!\nCMCNT = 0"];
00073 *   CMCOR => ISR [label="CMIn interrupt"];
00074 *   ISR => Callback [label="s_cmt_callback[n]()"];
00075 *   Callback » ISR;
00076 *   ISR » CMCNT [label="Return"];
00077 *   CMCNT -> CMCNT [label="Continue counting..."];
00078 * @endmsc
00079 *
00080 * ## Clock Divider Selection Algorithm
00081 *
00082 * The driver tries each divider in order (/8, /32, /128, /512) and selects
00083 * the first one that produces a period fitting in 16 bits:
00084 *
00085 * ```
00086 * period = (PCLKB / divider) / frequency
00087 * if (0 < period <= 65535): use this divider
00088 * ```
00089 *
00090 * | Divider | PCLKB/div | Min Period | Max Period |
00091 * |-----|-----|-----|-----|
00092 * | /8 | 7.5 MHz | 1 (7.5 MHz) | 65535 (115 Hz) |
00093 * | /32 | 1.875 MHz | 1 (1.875 MHz) | 65535 (29 Hz) |
00094 * | /128 | 468.75 kHz | 1 (469 kHz) | 65535 (7.2 Hz) |
00095 * | /512 | 117.2 kHz | 1 (117 kHz) | 65535 (1.8 Hz) |
00096 *
00097 * ## Memory Map (Static State)
00098 *
00099 * | Symbol | Size | Description |
00100 * |-----|-----|-----|
00101 * | s_cmt_initialized[] | 4 bytes | Per-channel init flags |
00102 * | s_cmt_callback[] | 16 bytes | Callback function pointers |
00103 * | s_cmt_user_data[] | 16 bytes | User data pointers |
00104 *
00105 * ***Total static allocation:** 36 bytes
00106 *
00107 * ## Register Access Pattern
00108 *
00109 * All register access uses inline accessor functions for type safety:
00110 * - `cmt0()`, `cmt1()`, `cmt2()`, `cmt3()` - Channel registers
00111 * - `cmt_ctrl()` - Control registers (CMSTR0, CMSTR1)
00112 * - `icu()` - Interrupt controller
00113 *
00114 * ## NASA Power of 10 Compliance
00115 *
00116 * | Rule | Implementation |
00117 * |-----|-----|
00118 * | Rule 1 | No goto/recursion, single return paths |
00119 * | Rule 2 | Bounded loop in internal_calculate_cmt_params() |

```

```

00120 * | Rule 3 | Static arrays only, no heap |
00121 * | Rule 4 | All functions under 60 lines |
00122 * | Rule 5 | Parameter validation in all public functions |
00123 * | Rule 6 | File-scope static with s_ prefix |
00124 * | Rule 7 | All return values checked |
00125 * | Rule 8 | C23 typed enums for all constants |
00126 * | Rule 9 | Single-level pointers only |
00127 * | Rule 10 | Clean with -Wall -Wextra -Werror |
00128 *
00129 * @see rx_cmt.h Public API declarations
00130 * @see rx72n_cmt_regs.h CMT register definitions

00216 * @struct rx_cmt_interrupt_config_t
00217 * @brief CMT interrupt routing and priority configuration
00218 *
00219 * @details
00220 * Bundles the CMT channel identifier with the desired ICU interrupt priority
00221 * level. Passed by value to internal_configure_cmt_interrupt() so that the
00222 * caller does not need to keep the structure alive after the call returns.
00223 *
00224 * The channel field selects which ICU interrupt vector to program (CMI0-CMI3),
00225 * and the priority field is written directly into the corresponding IPR[]
00226 * register.
00227 *
00228 * @invariant channel must be a valid rx_cmt_channel_t value (0-3)
00229 * @invariant priority must be in [k_ipr_level_min, k_ipr_level_max]
00230 *
00231 * @par Example:
00232 * @code{.c}
00233 * rx_cmt_interrupt_config_t irq_cfg = {
00234 *     .channel = k_cmt_channel_1,
00235 *     .priority = 5,
00236 * };
00237 * rx_err_t err = internal_configure_cmt_interrupt(irq_cfg);
00238 * @endcode
00239 *
00240 * @see internal_configure_cmt_interrupt() Sole consumer of this struct
00241 * @see rx_cmt_init() Constructs this struct inline before calling the above
00242 *
00243 * @since Version 1.0.0

=====
00337 */
00338
00339 /**
00340 * @brief Map a CMT channel enum to its hardware register base pointer
00341 *
00342 * @details
00343 * Uses a switch statement to convert a logical channel identifier into a
00344 * pointer to the corresponding volatile rx_cmt_channel_regs_t register block.
00345 * The four CMT channels (CMT0-CMT3) each have a distinct base address in the
00346 * RX72N memory map; the inline accessor functions cmt0()-cmt3() encode those
00347 * addresses in a type-safe manner.
00348 *
00349 * The default case returns nullptr, which every caller is expected to check
00350 * immediately after the call (NASA Rule 7 compliance).
00351 *
00352 *
00353 *
00354 * @pre channel is a member of rx_cmt_channel_t (0-3)
00355 * @pre Hardware register addresses must be accessible (clocks enabled before use)
00356 *
00357 * @post Return value, if non-null, points to the live hardware register block
00358 * @post Caller must validate the return value before dereferencing (Rule 7)
00359 *
00360 * @note Not thread-safe; the hardware registers are globally shared
00361 * @note This function never writes to hardware; it only computes an address
00362 *
00363 * @par Thread Safety:
00364 * Read-only address computation; no shared mutable state is accessed.
00365 *
00366 * @par Performance:
00367 * Execution time: ~1 cycle (single branch/address load with -O2)
00368 *
00369 * @par Example:
00370 * @code{.c}
00371 * volatile rx_cmt_channel_regs_t* cmt = internal_get_cmt_base(k_cmt_channel_2);
00372 * if (cmt == nullptr) {
00373 *     return k_rx_err_invalid_arg;
00374 * }

```

```

00375 * cmt->cmcnt = 0;
00376 * @endcode
00377 *
00378 * @see cmt0() Inline accessor for CMT0 base address
00379 * @see cmt1() Inline accessor for CMT1 base address
00380 * @see cmt2() Inline accessor for CMT2 base address
00381 * @see cmt3() Inline accessor for CMT3 base address
00382 *
00383 * @since Version 1.0.0
00384 */

00401 /**
00402  * @brief Calculate the optimal CMT clock divider and compare-match value for a target frequency
00403  *
00404  * @details
00405  * Iterates the four available PCLKB clock dividers (/8, /32, /128, /512) in
00406  * ascending order and selects the first divider whose resulting 16-bit period
00407  * value satisfies:
00408  *
00409  * ```
00410  * period = (PCLKB / divider) / frequency_hz
00411  * 0 < period <= 65535
00412  * ```
00413  *
00414  * The chosen divider index is returned in *divider (corresponding to the CKS
00415  * field of CMCR: 0=/8, 1=/32, 2=/128, 3=/512). The compare-match register
00416  * value is returned in *cmcor; the caller must subtract the adjustment constant
00417  * k_cmt_period_adj when writing to the hardware register.
00418  *
00419  * Algorithm steps:
00420  * 1. Validate output pointers are non-null
00421  * 2. Reject frequency_hz == 0 or frequency_hz > PCLKB/8 (maximum achievable)
00422  * 3. Loop i from k_cmt_divider_start to k_cmt_num_dividers - 1
00423  * 4. Compute period_calc = (PCLKB / dividers[i]) / frequency_hz
00424  * 5. If 0 < period_calc <= 65535, store i and period_calc, return k_rx_ok
00425  * 6. If no divider fits, return k_rx_err_invalid_arg
00426  *
00427  *
00428  *
00429  * @pre divider must point to a valid uint8_t storage location
00430  * @pre cmcor must point to a valid uint16_t storage location
00431  *
00432  * @post On k_rx_ok: *divider holds the CKS value (0-3) for CMCR
00433  * @post On k_rx_ok: *cmcor holds the period count; caller subtracts 1 before writing CMCR
00434  *
00435  * @note Not thread-safe; pure computation with no shared state modification
00436  * @note Uses a bounded loop (k_cmt_num_dividers iterations) -- NASA Rule 2 compliant
00437  *
00438  * @par Thread Safety:
00439  * Pure computation with no global or static state; safe to call from any context.
00440  *
00441  * @par Performance:
00442  * Execution time: ~5 cycles (loop unrolled at -O2 for 4 divider steps)
00443  *
00444  * @par Example:

00494 /**
00495  * @brief Enable the CMT module clock by clearing the MSTPCRB module-stop bit
00496  *
00497  * @details
00498  * Removes the CMT0-CMT3 peripheral from module-stop state so that the module
00499  * clock is supplied and its registers become accessible. The sequence is:
00500  *
00501  * 1. Unlock the write-protect register (PRCR) for PRC1 and PRC3 bits
00502  * 2. Clear bit k_cmt_mstpa_unit0 (bit 15) in MSTPCRA to enable CMT unit 0 (CMT0/CMT1)
00503  * 3. Clear bit k_cmt_mstpa_unit1 (bit 14) in MSTPCRA to enable CMT unit 1 (CMT2/CMT3)
00504  * 4. Re-lock the PRCR to prevent accidental modification
00505  *
00506  * This function must be called before any CMT register access; reading or
00507  * writing CMT registers while the module clock is stopped produces undefined
00508  * hardware behaviour on the RX72N.
00509  *
00510  * The function is idempotent: calling it when the module is already enabled
00511  * simply clears an already-clear bit, which is harmless.
00512  *
00513  *
00514  * @pre The system clock (PCLKB) must be running before calling this function
00515  * @pre No other task or ISR must be concurrently modifying MSTPCRB
00516  *
00517  * @post MSTPCRA bits 15 and 14 are cleared; CMT module clocks for all 4 channels are active
00518  * @post PRCR is locked upon return (prevents accidental MSTPCRB changes)
00519  *
00520  * @note Not thread-safe; PRCR unlock/lock is a non-atomic read-modify-write
00521  * @note Called once per system lifetime; subsequent calls are benign
00522  *
00523  * @par Thread Safety:
00524  * Not thread-safe. Call during system initialization before RTOS scheduler
00525  * starts, or with interrupts disabled.
00526  *
00527  * @par Performance:
00528  * Execution time: ~4 register writes; negligible overhead
00529  *
00530  * @par Example:
00531  * @code{.c}
00532  * // Called internally by rx_cmt_init(); not intended for direct use
00533  * internal_enable_cmt_module_clock();
00534  * // CMT registers are now accessible

00624
00625 /**
00626  * @brief Configure the ICU interrupt vector priority and enable for a CMT channel
00627  *
00628  * @details
00629  * Programs the Interrupt Controller Unit (ICU) to route and enable the
00630  * compare-match interrupt (CMIn) for the specified CMT channel. The three
00631  * ICU registers modified are:
00632  *
00633  * 1. **IPR[vector]** - Sets the interrupt priority level for the channel's
00634  *   CMIn vector to config.priority.
00635  * 2. **IER[index]** - Sets the enable bit for the channel's interrupt vector

```

```

00636 *   within the IER register array. The bit index and byte index are derived
00637 *   from the vector number.
00638 * 3. **IR[vector]** - Clears any pending interrupt flag before enabling, so
00639 *   a stale flag does not fire immediately after enable.
00640 *
00641 * The vector number is computed as k_vect_cmt0_cmi0 + config.channel, which
00642 * yields CMI0 for channel 0, CMI1 for channel 1, and so on.
00643 *
00644 *
00645 *
00646 * @pre config.channel must be in the range [0, k_cmt_max_channels)
00647 * @pre config.priority must be in [k_ipr_level_min, k_ipr_level_max]
00648 *
00649 * @post ICU IPR register for the channel's vector set to config.priority
00650 * @post ICU IER bit for the channel's vector enabled
00651 * @post ICU IR flag for the channel's vector cleared
00652 *
00653 * @note Not thread-safe; concurrent ICU modification from another context is unsafe
00654 * @note Clears IR before enabling to prevent a spurious first interrupt
00655 *
00656 * @par Thread Safety:
00657 * Not thread-safe. Must be called during initialization with interrupts disabled
00658 * or before the RTOS scheduler starts.
00659 *
00660 * @par Performance:
00661 * Execution time: ~4 register accesses; negligible overhead
00662 *
00663 * @par Example:
00664 * @code{.c}
00665 * rx_cmt_interrupt_config_t irq_cfg = {
00666 *   .channel = k_cmt_channel_1,
00667 *   .priority = 5,
00668 * };

00826 /**
00827 * @brief Validate channel and configuration pointer before CMT initialisation
00828 *
00829 * @details
00830 * Performs all parameter checking required before rx_cmt_init() proceeds to
00831 * hardware configuration. Validation is performed in this strict order:
00832 *
00833 * 1. Verify config pointer is non-null (k_rx_err_null_ptr)
00834 * 2. Verify channel is within [0, k_cmt_max_channels) (k_rx_err_invalid_arg)
00835 * 3. Reject channel 0, which is reserved for the ThreadX system-tick timer
00836 *    (k_rx_err_conflict)
00837 * 4. Verify interrupt priority is within [k_ipr_level_min, k_ipr_level_max]
00838 *    (k_rx_err_invalid_arg)
00839 *
00840 * Centralising these checks in a dedicated helper keeps the main rx_cmt_init()
00841 * function concise and ensures that every check is logged before returning.
00842 *
00843 *
00844 *
00845 * @pre config must be a pointer to a caller-owned rx_cmt_config_t (may be nullptr)
00846 * @pre channel must be a member of rx_cmt_channel_t
00847 *
00848 * @post On k_rx_ok: channel and *config are safe to use for hardware programming
00849 * @post On error: an error message has been emitted via rx_log_error()
00850 *
00851 * @note Not thread-safe; pure validation with no shared state modification
00852 * @note The lower-bound check `channel >= k_cmt_channel_0` is intentionally
00853 *        omitted to avoid -Wtype-limits: channel is uint8_t and k_cmt_channel_0 == 0,
00854 *        making the comparison always true
00855 *
00856 * @par Thread Safety:
00857 * Pure validation; no shared mutable state is modified. Safe to call from any
00858 * context, but the result may be stale if state changes after the call.
00859 *
00860 * @par Performance:
00861 * Execution time: ~4 comparisons; negligible overhead
00862 *
00863 * @par Example:
00864 * @code{.c}
00865 * rx_err_t err = internal_validate_cmt_init_params(k_cmt_channel_1, &config);
00866 * if (err != k_rx_ok) {
00867 *     return err;
00868 * }

=====
00964  * Public API Implementation
00965  *
=====
00966  */
00967
00968 /**
00969  * @brief Initialize a CMT channel for periodic interrupt generation
00970  *
00971  * @details
00972  * Configures a CMT (Compare Match Timer) channel to fire a user callback at the
00973  * requested frequency. Validates parameters, selects the optimal clock divider,
00974  * enables the module clock, stops the timer for safe configuration, programs
00975  * timer registers, configures the ICU interrupt routing, saves the callback,
00976  * and starts the timer.
00977  *

```

```

00978 **Algorithm steps:**
00979 * 1. Validate channel and config parameters via internal_validate_cmt_init_params()
00980 * 2. Obtain CMT channel register base via internal_get_cmt_base()
00981 * 3. Calculate optimal divider and CMCOR value via internal_calculate_cmt_params()
00982 * 4. Enable CMT module clock (clear MSTPCRB bit) via internal_enable_cmt_module_clock()
00983 * 5. Stop the timer to allow safe register writes via rx_cmt_stop()
00984 * 6. Program CMCR (divider + CMIE) and CMCOR via internal_configure_cmt_timer_registers()
00985 * 7. Configure ICU interrupt vector priority and enable via internal_configure_cmt_interrupt()
00986 * 8. Save callback pointer and mark channel initialized via internal_save_cmt_callback()
00987 * 9. Start the timer via rx_cmt_start()
00988
00989 **Clock divider selection:**
00990 * The driver iterates dividers /8, /32, /128, /512 and picks the first that
00991 * produces a period fitting in 16 bits:
00992 * @code
00993 * period = (PCLKB / divider) / frequency_hz
00994 * if (0 < period <= 65535): use this divider
00995 * @endcode
00996 *
00997 *
00998 *
00999 *
01000 * @pre config must point to a valid rx_cmt_config_t structure
01001 * @pre config->frequency_hz must be > 0 and <= PCLKB / 8 (7.5 MHz at 60 MHz PCLKB)
01002 * @pre channel must not be k_cmt_channel_0
01003 * @pre System clocks must be initialized (PCLKB = 60 MHz)
01004 *
01005 * @post Timer running at requested frequency
01006 * @post config->callback registered and called from ISR at each compare match
01007 * @post s_cmt_initialized[channel] set to true
01008 * @post ICU interrupt for the channel enabled at specified priority
01009 *
01010 * @note Not thread-safe - call once per channel during system initialization
01011 * @note Callback executes in interrupt context; keep it short and non-blocking
01012 * @warning CMT0 is reserved for ThreadX; do not use k_cmt_channel_0
01013 *
01014 * @par Thread Safety:
01015 * Not thread-safe. Call once per channel during initialization before starting
01016 * the RTOS scheduler or with interrupts disabled.
01017 *
01018 * @par Performance:
01019 * - Execution time: ~5 us (mostly register writes)
01020 * - Stack usage: 48 bytes
01021 *
01022 * @par Example:
01023 * @code{.c}
01024 * static void my_timer_cb(void* user_data)
01025 * {
01026 * // Called at 1 kHz from interrupt context
01027 * (void)user_data;

#include "rx_check.h"
#include "rx_register_protection.h"

```

Include dependency graph for rx_doc.c:

Enumerations

- enum `doc_init_state_t` : `uint8_t` { `k_doc_not_initialized` = 0 , `k_doc_initialized` = 1 }
DOC driver initialization state tracking.
- enum `doc_bit_widths_t` : `uint32_t` { `k_doc_mstpb_bit_one` = 1U }
Bit-width constants for shifting the module-stop bit into MSTPCRB.

Functions

- static `rx_err_t` `internal_docr_for_mode` (`rx_doc_mode_t` mode, `uint8_t` *docr_out)
Translate an `rx_doc_mode_t` into the corresponding DOCR bit pattern.
- static void `internal_enable_doc_clock` (void)
Enable the DOC module clock by clearing MSTPCRB.MSTPB6 under PRCR.PRC1.
- static void `internal_disable_doc_clock` (void)
Disable the DOC module clock by setting MSTPCRB.MSTPB6 under PRCR.PRC1.
- static void `internal_clear_dopcf` (void)
Clear the DOPCF flag while preserving the configured operating mode.
- static bool `internal_read_dopcf` (void)
Read and return the current DOPCF (operation completion flag).
- `rx_err_t` `rx_doc_init` (`rx_doc_mode_t` mode)
Initialize DOC in the selected operating mode.
- `rx_err_t` `rx_doc_set_reference` (`uint16_t` reference)

- Set the DOC compare reference (DODIR) register (implementation).
- `rx_err_t rx_doc_compare` (uint16_t value, bool *matched)
Compare value against the previously set DOC reference (implementation).
- `rx_err_t rx_doc_add` (uint16_t addend, uint16_t *sum, bool *overflow)
Perform a hardware-accelerated 16-bit add (implementation).
- `rx_err_t rx_doc_subtract` (uint16_t subtrahend, uint16_t *difference, bool *borrow)
Perform a hardware-accelerated 16-bit subtract (implementation).
- `rx_err_t rx_doc_deinit` (void)
Deinitialize the DOC peripheral and gate its clock (implementation).

Variables

- static const char *const `s_tag` = "DOC"
Log tag for this driver.
- static `doc_init_state_t s_doc_init_state` = `k_doc_not_initialized`
Tracks whether the DOC driver has been initialized.
- static `rx_doc_mode_t s_doc_mode` = `k_rx_doc_mode_compare`
Current DOC operating mode (valid only when `s_doc_init_state` == initialized).

8.113.1 Detailed Description

RX72N DOC (Data Operation Circuit) Driver Implementation.

Driver for the Renesas RX72N Data Operation Circuit – a small fixed-function 16-bit compute accelerator supporting four operating modes:

<code>rx`doc`mode` t</code>	OMS	DCSEL	Flag (DOPCF) Triggered On
<code>k_rx_doc_mode_compare</code>	00	1	DODIR == DODSR
<code>k_rx_doc_mode_compare_neq</code>	00	0	DODIR != DODSR
<code>k_rx_doc_mode_add</code>	01	x	Carry past 0xFFFF
<code>k_rx_doc_mode_subtract</code>	10	x	Borrow below 0x0000

8.113.1.1 Initialization Sequence

1. Validate the requested mode against `rx_doc_mode_t`.
2. Unlock PRCR (PRC1) and clear MSTPCRB.MSTPB6 to enable the DOC module clock.
3. Re-lock PRCR.
4. Write DOCR with the mode + DCSEL + DOPCFCL (clears any stale DOPCF).
5. Record the mode and flag the driver as initialized.

8.113.1.2 DOPCF Clearing

DOPCF (DOCR bit 5) is read-only; the peripheral clears it only when 1 is written to DOPCFCL (bit 6). Every operation writes DODSR to trigger the computation, reads DOPCF, then writes DOPCFCL | (current mode bits) back to DOCR to leave the mode untouched while clearing the flag.

8.113.1.3 Mode Switching

Re-calling `rx_doc_init()` with a different mode is the supported path to switch; mode mismatches between the configured operation and the API call return `k_rx_err_invalid_state`.

00086 } doc_init_state_t;
```

8.113.3 Function Documentation

8.113.3.1 internal`clear`dopcf()

```
void internal_clear_dopcf (
    void ) [static]
```

Clear the DOPCF flag while preserving the configured operating mode.

Writes DOCR = (mode bits) | DOPCFCL. DOPCFCL is write-1-to-clear and leaves the mode fields (OMS, DCSEL) unchanged. `s_doc_mode` is guaranteed to be a valid enumerator whenever `s_doc_init_state == k_doc_initialized`, so the [internal_docr_for_mode\(\)](#) call cannot fail here.

Precondition

Driver must be initialized (`s_doc_init_state == k_doc_initialized`)

Postcondition

DOPCF is cleared

OMS / DCSEL / DOPCIE unchanged from their configured values

Since

Version 1.0.0

Definition at line 229 of file [rx_doc.c](#).

```
00230 {
00231     uint8_t mode_bits = 0U;
00232     (void)internal_docr_for_mode(s_doc_mode, &mode_bits);
00233     doc()->docr = (uint8_t)(mode_bits | k_doc_dopcfcl_clear);
00234 }
```

Here is the caller graph for this function:

8.113.3.2 `internal_disable_doc_clock()`

```
void internal_disable_doc_clock (  
    void ) [static]
```

Disable the DOC module clock by setting MSTPCRB.MSTPB6 under PRCR.PRC1.

Precondition

[prcr_reg\(\)](#) is writable

Postcondition

MSTPCRB.MSTPB6 == 1 (DOC module clock stopped)
PRCR is re-locked

Note

See [internal_enable_doc_clock\(\)](#) for the rationale on the absence of a [system_regs\(\)](#) null check.

Here is the call graph for this function:

Here is the caller graph for this function:

8.113.3.3 `internal_docr_for_mode()`

```
rx_err_t internal_docr_for_mode (
    rx_doc_mode_t mode,
    uint8_t * docr_out) [static]
```

Translate an `rx_doc_mode_t` into the corresponding DOCR bit pattern.

Validates mode and, on success, writes the DOCR bit pattern (OMS + DCSEL

- DOPCIE disabled) for the requested mode into `docr_out`. DOPCFCL is left clear; the caller OR's it in when a flag clear is needed.

Combining the validation and the encoding in a single step eliminates the dead "unknown mode" branch that would otherwise exist in a pure encoder.

Precondition

`docr_out != NULL`

Postcondition

On success, `*docr_out` has `DOPCFCL == 0`

Manual Reference

RX72N HW Manual Section 59.2 "DOCR" (page 2970): OMS[1:0], DCSEL, DOPCIE layout.

Note

Pure function – no side effects, safe to call anywhere.

Referenced by `internal_clear_dopcf()`, and `rx_doc_init()`.

Here is the caller graph for this function:

8.113.3.4 internal`enable`doc`clock()

```
void internal_enable_doc_clock (
    void ) [static]
```

Enable the DOC module clock by clearing MSTPCRB.MSTPB6 under PRCR.PRC1.

Sequence:

1. Unlock PRCR (PRC1) via `k_rx_prcr_unlock_prc1`.
2. Clear bit `k_doc_mstpb_bit` (bit 6) in MSTPCRB.
3. Re-lock PRCR via `k_rx_prcr_lock`.

Precondition

`prcr_reg()` is writable

Postcondition

MSTPCRB.MSTPB6 == 0 (DOC module clock running)
 PRCR is re-locked (`k_rx_prcr_lock`)

Note

`system_regs()` is an inline accessor for a fixed memory-mapped address (`k_rx_system_regs_base`), so it is guaranteed non-NULL and no runtime check is performed (would be dead code per NASA Power of 10).

Not thread-safe; call during single-threaded init.

Since

Version 1.0.0

Definition at line 190 of file `rx_doc.c`.

```
00191 {
00192  *prcr_reg() = k_rx_prcr_unlock_prc1;
00193  system_regs()->mstpcrb &= ~(k_doc_mstpb_bit_one « k_doc_mstpb_bit);
00194  *prcr_reg() = k_rx_prcr_lock;

Here is the caller graph for this function:

8.113.3.6 rx`doc`add()

```

rx_err_t rx_doc_add (
    uint16_t addend,
    uint16_t * sum,
    bool * overflow)

```

Perform a hardware-accelerated 16-bit add (implementation).

Execute a 16-bit add using the DOC.

Writes the addend into DODSR; the DOC then computes $\text{sum} = \text{DODIR} + \text{addend}$ with overflow flagged in DOPCF. Reads the result back through DODSR (post-operation register) and reports the overflow flag, then clears DOPCF before return.

Note

Not thread-safe. Serialize access to the global DOC peripheral.

Definition at line 333 of file `rx_doc.c`.

```

00334 {
00335     RX_CHECK_NULL_PTR(sum, s_tag, "rx_doc_add: sum is NULL");
00336     RX_CHECK_NULL_PTR(overflow, s_tag, "rx_doc_add: overflow is NULL");
00337
00338     if (s_doc_init_state != k_doc_initialized) {
00339         rx_log_error(s_tag, "rx_doc_add: driver not initialized");
00340         return k_rx_err_not_initialized;
00341     }
00342     if (s_doc_mode != k_rx_doc_mode_add) {
00343         rx_log_error(s_tag, "rx_doc_add: driver not in add mode");
00344         return k_rx_err_invalid_state;
00345     }
00346
00347     doc()->dodsr = addend;
00348     *sum        = doc()->dodsr;
00349     *overflow    = internal_read_dopcf();
00350     internal_clear_dopcf();
00351     return k_rx_ok;
00352 }

```

References `doc()`, `rx_doc_regs_t::dodsr`, `internal_clear_dopcf()`, `internal_read_dopcf()`, `k_doc_initialized`, `k_rx_doc_mode_add`, `s_doc_init_state`, `s_doc_mode`, and `s_tag`.

Here is the call graph for this function:

8.113.3.7 rx'doc'compare()

```
rx_err_t rx_doc_compare (
    uint16_t value,
    bool * matched)
```

Compare value against the previously set DOC reference (implementation).

Execute a compare operation against the loaded reference.

Writes value into DODSR, latches the comparator flag (DOPCF), and reports whether the configured compare condition is satisfied. In `k_rx_doc_mode_compare` the flag is set on equality; in `k_rx_doc_mode_compare_neq` the flag is set on inequality. The comparator flag is cleared internally before return so successive compares are independent.

Note

Not thread-safe. Serialize access to the global DOC peripheral.

Definition at line 303 of file `rx_doc.c`.

```
00304 {
00305     RX_CHECK_NULL_PTR(matched, s_tag, "rx_doc_compare: matched is NULL");
00306
00307     if (s_doc_init_state != k_doc_initialized) {
00308         rx_log_error(s_tag, "rx_doc_compare: driver not initialized");
00309         return k_rx_err_not_initialized;
00310     }
00311     if ((s_doc_mode != k_rx_doc_mode_compare) && (s_doc_mode != k_rx_doc_mode_compare_neq)) {
00312         rx_log_error(s_tag, "rx_doc_compare: driver not in a compare mode");
00313         return k_rx_err_invalid_state;
00314     }
00315
00316     doc()->dodsr = value;
00317     *matched = internal_read_dopcf();
00318     internal_clear_dopcf();
00319     return k_rx_ok;
00320 }
```

Here is the call graph for this function:

8.113.3.8 rx'doc'deinit()

```
rx_err_t rx_doc_deinit (
    void )
```

Deinitialize the DOC peripheral and gate its clock (implementation).

Deinitialize DOC and gate its clock.

Idempotent: returns `k_rx_ok` immediately if the driver was not initialized. Otherwise clears `DOC->DOCR` (mode register), disables the DOC module clock through `internal_disable_doc_clock()`, and marks the driver as uninitialized.

Note

Not thread-safe. Serialize access to the global DOC peripheral.

Definition at line 397 of file [rx_doc.c](#).

```
00398 {
00399     if (s_doc_init_state != k_doc_initialized) {
00400         return k_rx_ok;
00401     }
00402
00403     doc()->docr = 0U;
00404     internal_disable_doc_clock();
00405
00406     s_doc_init_state = k_doc_not_initialized;
00407     return k_rx_ok;
00408 }
```

References [doc\(\)](#), [rx_doc_regs_t::docr](#), [internal_disable_doc_clock\(\)](#), [k_doc_initialized](#), [k_doc_not_initialized](#), and [s_doc_init_state](#).

Here is the call graph for this function:

8.113.3.9 rx`doc`init()

```
rx_err_t rx_doc_init (
    rx_doc_mode_t mode)
```

Initialize DOC in the selected operating mode.

Powers on the DOC (clears MSTPCRB.MSTPB6 under PRCR.PRC1 unlock), then configures DOCR with the requested operation mode, clears any stale DOPCF, and marks the driver initialized.

Subsequent operations expect the driver to remain in this mode until [rx_doc_init\(\)](#) is called again with a different mode (re-init is allowed and is the supported way to switch modes).

Parameters

in	mode	Operating mode to configure
----	------	-----------------------------

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Success
<code>k_rx_err_invalid_arg</code>	mode is not a valid <code>rx_doc_mode_t</code> value

Precondition

PRCR accessor (`prcr_reg()`) is addressable
MSTPCRB is writable once PRCR.PRC1 is unlocked

Postcondition

DOC module stop bit cleared (`MSTPCRB.MSTPB6 = 0`)
DOCR configured for the requested mode, `DOPCIE = 0`, `DOPCF` cleared
Driver is marked initialized

Note

Not thread-safe. Caller must serialize DOC access.

Here is the call graph for this function:

8.113.3.10 rx`doc`set`reference()

```
rx_err_t rx_doc_set_reference (
    uint16_t reference)
```

Set the DOC compare reference (DODIR) register (implementation).

Load the DOC reference value (DODIR) used for the next operation.

Writes the supplied 16-bit reference value into the Data Operation Circuit Input register (DODIR) that subsequent [rx_doc_compare\(\)](#) / [rx_doc_add\(\)](#) / [rx_doc_subtract\(\)](#) calls operate against. Validates driver init state but does not validate or constrain the value range (any 16-bit value is meaningful in compare/add/subtract modes).

Note

Not thread-safe. The DOC peripheral is global; serialize access at the application layer.

Definition at line 280 of file [rx_doc.c](#).

```
00281 {
00282     RX_VALIDATE_INIT(s_doc_init_state == k_doc_initialized,
00283                     s_tag,
00284                     "rx_doc_set_reference: driver not initialized");
00285
00286     doc()->dodir = reference;
00287     return k_rx_ok;
00288 }
```

References [doc\(\)](#), [rx_doc_regs_t::dodir](#), [k_doc_initialized](#), [s_doc_init_state](#), and [s_tag](#).

Here is the call graph for this function:

8.113.3.11 rx`doc`subtract()

```
rx_err_t rx_doc_subtract (
    uint16_t subtrahend,
    uint16_t * difference,
    bool * borrow)
```

Perform a hardware-accelerated 16-bit subtract (implementation).

Execute a 16-bit subtract using the DOC.

Writes subtrahend into DODSR; the DOC computes difference = DODIR - subtrahend with borrow flagged in DOPCF. Reads the result back through DODSR and reports the borrow flag, then clears DOPCF before return.

Note

Not thread-safe. Serialize access to the global DOC peripheral.

Definition at line 365 of file [rx_doc.c](#).

```

00366 {
00367     RX_CHECK_NULL_PTR(difference, s_tag, "rx_doc_subtract: difference is NULL");

8.113.4 Variable Documentation

8.113.4.1 s'doc'init'state

[doc_init_state_t](#) s_doc_init_state = [k_doc_not_initialized](#) [static]

Tracks whether the DOC driver has been initialized.

Since

Version 1.0.0

Definition at line 114 of file [rx_doc.c](#).

Referenced by [rx_doc_add\(\)](#), [rx_doc_compare\(\)](#), [rx_doc_deinit\(\)](#), [rx_doc_init\(\)](#), [rx_doc_set_reference\(\)](#), and [rx_doc_subtract\(\)](#).

8.113.4.2 s`doc`mode

```
rx_doc_mode_t s_doc_mode = k_rx_doc_mode_compare [static]
```

Current DOC operating mode (valid only when s_doc_init_state == initialized).

Since

Version 1.0.0

Definition at line 121 of file rx_doc.c.

Referenced by [internal_clear_dopcf\(\)](#), [rx_doc_add\(\)](#), [rx_doc_compare\(\)](#), [rx_doc_init\(\)](#), and [rx_doc_subtract\(\)](#).

8.113.4.3 s`tag

```
const char* const s_tag = "DOC" [static]
```

Log tag for this driver.

Since

Version 1.0.0

Definition at line 107 of file rx_doc.c.

8.114 rx`doc.c

00001 /**
00002  * @file rx_doc.c
00003  * @brief RX72N DOC (Data Operation Circuit) Driver Implementation
00004  *
00005  * @details
00006  * Driver for the Renesas RX72N Data Operation Circuit -- a small fixed-function
00007  * 16-bit compute accelerator supporting four operating modes:
00008  *
00009  * | rx_doc_mode_t | OMS | DCSEL | Flag (DOPCF) Triggered On |
00010  * |-----|-----|-----|
00011  * | k_rx_doc_mode_compare | 00 | 1 | DODIR == DODSR |
00012  * | k_rx_doc_mode_compare_neq | 00 | 0 | DODIR != DODSR |
00013  * | k_rx_doc_mode_add | 01 | x | Carry past 0xFFFF |
00014  * | k_rx_doc_mode_subtract | 10 | x | Borrow below 0x0000 |
00015  *
00016  * ## Initialization Sequence
00017  *
00018  * 1. Validate the requested mode against rx_doc_mode_t.
00019  * 2. Unlock PRCR (PRC1) and clear MSTPCRB.MSTPB6 to enable the DOC module clock.
00020  * 3. Re-lock PRCR.
00021  * 4. Write DOCR with the mode + DCSEL + DOPCFCL (clears any stale DOPCF).
00022  * 5. Record the mode and flag the driver as initialized.
00023  *
00024  * ## DOPCF Clearing
00025  *
00026  * DOPCF (DOCR bit 5) is read-only; the peripheral clears it only when 1 is
00027  * written to DOPCFCL (bit 6). Every operation writes DODSR to trigger the
00028  * computation, reads DOPCF, then writes DOPCFCL | (current mode bits) back to
00029  * DOCR to leave the mode untouched while clearing the flag.
00030  *
00031  * ## Mode Switching
00032  *
00033  * Re-calling rx_doc_init() with a different mode is the supported path to
```

```

00034 * switch; mode mismatches between the configured operation and the API call
00035 * return k_rx_err_invalid_state.

```

Enumerations

- enum `rx_eccram_fill_t` : `uint32_t { k_rx_eccram_fill_pattern = 0x00000000U }`
Zero-initialisation fill pattern and word size.
- enum `rx_eccram_word_size_t` : `uint32_t { k_rx_eccram_word_bytes = 4 }`
Width of a single ECC-protected word in bytes.
- enum `rx_eccram_word_count_t` : `uint32_t { k_rx_eccram_word_count = (k_rx_eccram_region_size_bytes / k_rx_eccram_word_bytes) }`
Number of 32-bit words in the ECCRAM region.

Functions

- static `uint8_t internal_mode_to_reg(rx_eccram_mode_t mode)`
Translate public mode enum into ECCRAMMODE register value.
- static void `internal_enable_eccram_module_clock(void)`
Clear MSTPCRC.MSTPC6 so ECCRAM control block is clocked.
- static void `internal_write_eccram_mode(uint8_t mode_reg_value)`
Write ECCRAMMODE under ECCRAMPRCR unlock.
- static void `internal_enable_1bit_latch(void)`
Enable the 1-bit status-update latch.
- static void `internal_zero_fill_region(void)`
Zero-initialise the ECCRAM region with 32-bit stores.
- static void `internal_ram_error_isr_body(void)`
Shared RAM error handler core.
- void `rx_eccram_ram_error_isr(void)`
Vector-18 ISR entry (RAMERR) – ECCRAM 1-bit/2-bit error.
- `rx_err_t rx_eccram_init(rx_eccram_mode_t mode)`
Initialise ECCRAM in the requested operating mode.
- `rx_err_t rx_eccram_get_error_status(rx_eccram_status_t *out)`
Read a snapshot of ECCRAM error status and captured addresses.
- `rx_err_t rx_eccram_clear_errors(void)`
Clear 1-bit and 2-bit error status flags.
- `rx_err_t rx_eccram_register_error_isr(rx_eccram_on_1bit_fn_t on_1bit, rx_eccram_on_2bit_fn_t on_2bit, void *ctx)`
Register user callbacks for ECC error ISRs.
- `uintptr_t rx_eccram_region_start(void)`
Return the inclusive start address of the ECCRAM data region.
- `uintptr_t rx_eccram_region_end(void)`
Return the inclusive end address of the ECCRAM data region.

Variables

- static const char *const [s_tag](#) = "ECCRAM"
Module log tag for rx_log_* macros.
- static bool [s_initialized](#) = false
Driver initialised flag.
- static [rx_eccram_on_1bit_fn_t s_on_1bit](#) = NULL
Registered 1-bit error callback (may be nullptr).
- static [rx_eccram_on_2bit_fn_t s_on_2bit](#) = NULL
Registered 2-bit error callback (may be nullptr).
- static void * [s_isr_ctx](#) = NULL
Opaque context passed to registered callbacks.
- static volatile uintptr_t [s_last_2bit_addr](#) = 0
Latched address of most recent 2-bit error (captured in ISR).
- static volatile uintptr_t [s_last_1bit_addr](#) = 0
Latched address of most recent 1-bit error (captured in ISR).

8.115.1 Detailed Description

ECC-Protected RAM (ECCRAM) Driver Implementation.

Implements the [rx_eccram.h](#) API: module-stop clear, mode configuration under PRCR unlock, region zero-initialisation with 32-bit stores, error-status readout, flag clearing, ISR trampoline, and region introspection.

The RX72N has a single RAMERR vector (vector 18, RAM group) that fires for both 1-bit and 2-bit ECCRAM errors. The ISR trampoline inspects ECCRAM1STS and ECCRAM2STS to decide which registered handler (if any) to invoke, captures the failing address(es), and clears the latched status flags.

Register Protection Sequencing

Two independent protection registers are involved:

- System PRCR (0x000803FE) protects MSTPCRC (Manual Ch11). Unlock with `k_rx_prcr_unlock_prc1`, write MSTPCRC, re-lock with `k_rx_prcr_lock`.
- ECCRAMPRCR (0x000812C4) protects ECCRAMMODE and ECCRAM1STSEN (Manual section 60.2.13). Unlock with `k_rx_eccramprcr_unlock` (0xF1), write the guarded register, re-lock with `k_rx_eccramprcr_lock` (0xF0).

8.115.2 Enumeration Type Documentation

8.115.2.1 rx`eccram`fill`_t

```
enum rx_eccram_fill_t : uint32_t
```

Zero-initialisation fill pattern and word size.

The ECC syndrome is computed per 32-bit word; filling with zero is the cheapest pattern that produces a well-defined, check-valid state.

Since

Version 1.0.0

Enumerator

k_rx_eccram_fill_pattern	Fill pattern used by the zero-initialisation loop.
--------------------------	--

Definition at line 73 of file [rx_eccram.c](#).

```
00073      : uint32_t {
00074  /** @brief Fill pattern used by the zero-initialisation loop */
00075  k_rx_eccram_fill_pattern = 0x00000000U,
00076 } rx_eccram_fill_t;
```

8.115.2.2 rx`eccram`word`count`_t

```
enum rx_eccram_word_count_t : uint32_t
```

Number of 32-bit words in the ECCRAM region.

Since

Version 1.0.0

Enumerator

k_rx_eccram_word_count	32 KB / 4 bytes per word = 8192 words
------------------------	---------------------------------------

Definition at line 99 of file [rx_eccram.c](#).

```
00099      : uint32_t {
00100  /** @brief 32 KB / 4 bytes per word = 8192 words */
00101  k_rx_eccram_word_count = (k_rx_eccram_region_size_bytes / k_rx_eccram_word_bytes),
00102 } rx_eccram_word_count_t;
```

8.115.2.3 rx_eccram_word_size_t

```
enum rx_eccram_word_size_t : uint32_t
```

Width of a single ECC-protected word in bytes.

Declared as a typed enum so it can bound the Rule-2 static loop upper in `rx_eccram_init()` without introducing a magic number.

Since

Version 1.0.0

Enumerator

k_rx_eccram_word_bytes	4 bytes per ECC word (uint32_t)
------------------------	---------------------------------

Definition at line 88 of file `rx_eccram.c`.

```
00088      : uint32_t {
00089      /** @brief 4 bytes per ECC word (uint32_t) */
00090      k_rx_eccram_word_bytes = 4,
00091  } rx_eccram_word_size_t;
```

8.115.3 Function Documentation

8.115.3.1 internal_enable_1bit_latch()

```
void internal_enable_1bit_latch (
    void ) [static]
```

Enable the 1-bit status-update latch.

Sets ECCRAM1STSEN=1 so that 1-bit errors are latched into ECCRAM1STS and ECCRAM1ECAD. Skipped for k_eccram_mode_disabled. Guarded by ECCRAMPRCR (shared with ECCRAMMODE).

Precondition

ECCRAM module clocked.

Postcondition

ECCRAM1STSEN.ECC1STSEN == 1.
ECCRAMPRCR is re-locked on return.

Since

Version 1.0.0

Definition at line 210 of file [rx_eccram.c](#).

```
00211 {
00212     volatile rx_eccram_regs_t* regs = eccram_regs();
00213     regs->eccramprcr = k_rx_eccramprcr_unlock;
00214     regs->eccram1tsen = k_rx_eccram1tsen_enable;
00215     regs->eccramprcr = k_rx_eccramprcr_lock;
00216 }
```

Here is the call graph for this function:

Here is the caller graph for this function:

8.115.3.2 internal_enable_eccram_module_clock()

```
void internal_enable_eccram_module_clock (
    void ) [static]
```

Clear MSTPCRC.MSTPC6 so ECCRAM control block is clocked.

Uses the standard STAR unlock/write/lock sequence on the system PRCR.

Precondition

System clock configured.

Caller holds exclusive access to MSTPCRC (single-threaded init).

Postcondition

MSTPCRC.MSTPC6 == 0.

System PRCR is re-locked on return.

Here is the call graph for this function:

Here is the caller graph for this function:

8.115.3.3 `internal_mode_to_reg()`

```
uint8_t internal_mode_to_reg (
    rx\_eccram\_mode\_t mode) [static]
```

Translate public mode enum into ECCRAMMODE register value.

Precondition

`mode` has been range-checked by the caller.

Postcondition

Return value is one of the `k_rx_eccrammode_*` constants.

Note

All error-visible modes share the same hardware encoding (RAMMOD=11b). The distinction between `correct_only`, `correct_and_detect`, and `detect_only` is enforced by which ISRs the driver registers (not by the hardware bits).

Since

Version 1.0.0

Definition at line 147 of file [rx_eccram.c](#).

```
00148 {
00149     if (mode == k_eccram_mode_disabled) {
00150         return k_rx_eccrammode_ecc_disabled;
00151     }
00152     return k_rx_eccrammode_ecc_with_check;
00153 }
```

Here is the caller graph for this function:

8.115.3.4 `internal`ram`error`isr`body()`

```
void internal_ram_error_isr_body (
    void ) [static]
```

Shared RAM error handler core.

Called from the `__attribute__((interrupt))` wrapper below. Reads both status flags, captures the corresponding address registers, dispatches to registered user callbacks, and clears the flags so the next error can be detected.

The 2-bit branch captures ECCRAM2ECAD into `s_last_2bit_addr` before the flag-clearing write, matching the prompt requirement that the failing address be saved first.

Precondition

Called from IRQ context on vector 18 (RAMERR).

Postcondition

ECCRAM1STS and ECCRAM2STS flags cleared.

`s_last_1bit_addr` / `s_last_2bit_addr` updated on match.

Since

Version 1.0.0

Definition at line 310 of file [rx_eccram.c](#).

```

00311 {
00312     volatile rx_eccram_regs_t* regs = eccram_regs();
00313
00314     const uint8_t status2 = regs->eccram2sts;
00315     if ((status2 & k_rx_eccram2sts_ecc2err_mask) != 0U) {
00316         const uintptr_t addr2 = (uintptr_t)regs->eccram2ecad;

Here is the caller graph for this function:

8.115.3.5 internal_write_eccram_mode()

```

void internal_write_eccram_mode (
    uint8_t mode_reg_value) [static]

```

Write ECCRAMMODE under ECCRAMPCR unlock.

Precondition

ECCRAM module clocked (MSTPCRC.MSTPC6 == 0).
mode_reg_value is a valid [k_rx_eccrammode_*](#) constant.

Postcondition

ECCRAMMODE reflects mode_reg_value.

ECCRAMPRCR is re-locked on return.

Here is the call graph for this function:

Here is the caller graph for this function:

8.115.3.6 internal_zero_fill_region()

```
void internal_zero_fill_region (
    void ) [static]
```

Zero-initialise the ECCRAM region with 32-bit stores.

Iterates over every 32-bit word in ECCRAM and writes zero so that every ECC syndrome matches. The loop upper bound is a compile-time constant ([k_rx_eccram_word_count](#)), which satisfies NASA Rule 2.

Precondition

ECCRAMMODE == [k_rx_eccrammode_ecc_no_check](#) (so writes generate syndromes but reads do not trigger spurious errors).

Postcondition

Every 32-bit word of ECCRAM holds `k_rx_eccram_fill_pattern`.

Note

Runs in ~65 k cycles on RX72N at 240 MHz (~270 us).

Since

Version 1.0.0

Definition at line 272 of file [rx_eccram.c](#).

```
00273 {
00274 #ifdef UNIT_TEST
00275     for (uint32_t i = 0; i < k_rx_eccram_word_count; i++) {
00276         g_mock_eccram_region[i] = k_rx_eccram_fill_pattern;
00277     }
00278 #else
00279     volatile uint32_t* dst = (volatile uint32_t*)k_rx_eccram_region_base_addr;
00280     for (uint32_t i = 0; i < k_rx_eccram_word_count; i++) {
00281         dst[i] = k_rx_eccram_fill_pattern;
00282     }
00283 #endif
00284 }
```

Here is the caller graph for this function:

8.115.3.7 rx_eccram_clear_errors()

```
rx_err_t rx_eccram_clear_errors (
    void ) [nodiscard]
```

Clear 1-bit and 2-bit error status flags.

Writes `k_rx_eccram1sts_clear` and `k_rx_eccram2sts_clear` to acknowledge any outstanding error flags. Does not touch the captured addresses: those remain latched until the next error.

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Flags cleared.
----------------------	----------------

Precondition

`rx_eccram_init()` has been called.

ECCRAMPRCR protection does not guard ECCRAM1STS/ECCRAM2STS (verified in Manual section 60.2.13 – both registers are directly writable without PRCR unlock).

Postcondition

`ECCRAM1STS.ECC1ERR == 0` and `ECCRAM2STS.ECC2ERR == 0`.

Note

Thread Safety: Call from ISR or task context; writes are atomic.

Since

Version 1.0.0

Definition at line 433 of file `rx_eccram.c`.

```
00434 {
00435     volatile rx_eccram_regs_t* regs = eccram_regs();
00436     regs->eccram1sts          = k_rx_eccram1sts_clear;
00437     regs->eccram2sts          = k_rx_eccram2sts_clear;
00438     return k_rx_ok;
00439 }
```

References `rx_eccram_regs_t::eccram1sts`, `rx_eccram_regs_t::eccram2sts`, `eccram_regs()`, `k_rx_eccram1sts_clear`, and `k_rx_eccram2sts_clear`.

Here is the call graph for this function:

8.115.3.8 rx`eccram`get`error`status()

```
rx_err_t rx_eccram_get_error_status (
    rx_eccram_status_t * out) [nodiscard]
```

Read a snapshot of ECCRAM error status and captured addresses.

Reads ECCRAM1STS, ECCRAM2STS, ECCRAM1ECAD, and ECCRAM2ECAD into a plain struct. No registers are modified – call `rx_eccram_clear_errors()` to acknowledge faults.

Parameters

out	out	Pointer to status struct populated on success.
-----	-----	--

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Status read successfully.
<code>k_rx_err_null_ptr</code>	out is nullptr.

Precondition

[rx_eccram_init\(\)](#) has been called.
out is a valid writable pointer.

Postcondition

out fields reflect the register state at call time.
No hardware state is modified by this call.

Note

Thread Safety: Safe for concurrent readers (pure register reads).

Since

Version 1.0.0

Definition at line 416 of file [rx_eccram.c](#).

```

00417 {
00418     RX_CHECK_NULL_PTR(out, s_tag, "out is nullptr");

Here is the call graph for this function:

8.115.3.9 rx`eccram`init()

```
rx_err_t rx_eccram_init (
    rx_eccram_mode_t mode) [nodiscard]
```

Initialise ECCRAM in the requested operating mode.

Performs the full initialisation sequence required by the RX72N HW manual:

1. Clear MSTPCRC.MSTPC6 under system PRCR unlock so that the ECCRAM control block is clocked (Manual section 60.4.1, page 2994).
2. Unlock ECCRAMPRCR and set ECCRAMMODE = k_rx_eccrammode_ecc_no_check so ECC bits are generated but nothing is checked.
3. Zero all 32 KB of ECCRAM using aligned 32-bit stores (Manual section 60.3.3: uninitialised ECC syndromes would falsely flag).
4. Switch ECCRAMMODE to the mode that backs the requested mode argument and re-lock ECCRAMPRCR.
5. For any mode other than k_eccram_mode_disabled, enable the 1-bit status-update latch (ECCRAM1STSEN).

Parameters

in	mode	Desired operating mode (see rx_eccram_mode_t)
----	------	---

Returns

rx_err_t Error code

Return values

k_rx_ok	Initialisation successful.
k_rx_err_invalid_arg	mode is outside rx_eccram_mode_t range.
k_rx_err_hw_init_failed	Hardware mode read-back did not match.

Precondition

System clock is configured before this call.

Interrupts are globally disabled OR this function is called before any task can generate ECCRAM traffic.

Postcondition

MSTPCRC.MSTPC6 == 0 (ECCRAM control block clocked).

All 32 KB of ECCRAM are zeroed with matching ECC syndromes.

ECCRAMMODE reflects mode.

Note

Thread Safety: Call once from `hardware_init()`. Not reentrant.

Warning

This function must run before any data is placed in the `.eccram` linker section – it wipes the region.

NASA Power of 10 Compliance:

- Rule 2: Zero-fill loop bounded by `k_rx_eccram_region_size_bytes / 4`.
- Rule 5: 2 preconditions, 3 postconditions.
- Rule 7: Every internal helper's return value is checked.

Here is the call graph for this function:

8.115.3.10 rx`eccram`ram`error`isr()

```
void rx_eccram_ram_error_isr (
    void )
```

Vector-18 ISR entry (RAMERR) – ECCRAM 1-bit/2-bit error.

The GNURX toolchain's vector table dispatches to this symbol; the interrupt attribute generates the correct prologue/epilogue.

Precondition

Vector 18 is enabled and wired to this symbol by the boot code.

Postcondition

[internal_ram_error_isr_body\(\)](#) has run to completion.

See also

[internal_ram_error_isr_body\(\)](#)

Here is the call graph for this function:

8.115.3.11 rx_eccram_region_end()

```
uintptr_t rx_eccram_region_end (
    void )
```

Return the inclusive end address of the ECCRAM data region.

Returns

Physical address 0x00FFFFFF as a `uintptr_t`.

Precondition

None.

Postcondition

Return value equals `k_rx_eccram_region_end_addr`.

Return value - [rx_eccram_region_start\(\)](#) + 1 equals 32 KB.

Note

Thread Safety: Returns a compile-time constant; always safe.

See also

[rx_eccram_region_start\(\)](#)

00466 {
00467     return k_rx_eccram_region_end_addr;
00468 }
```

References [k_rx_eccram_region_end_addr](#).

8.115.3.12 rx_eccram_region_start()

```
uintptr_t rx_eccram_region_start (  
    void )
```

Return the inclusive start address of the ECCRAM data region.

Exposes the hardware-defined base of the ECC-protected region so that linker scripts and runtime allocators can place objects inside it without hardcoding the literal address.

Returns

Physical address 0x00FF8000 as a `uintptr_t`.

Precondition

None.

Postcondition

Return value equals `k_rx_eccram_region_base_addr`.

Return value is word-aligned.

Note

Thread Safety: Returns a compile-time constant; always safe.

00463 }
```

References [k_rx_eccram_region_base_addr](#).

8.115.3.13 `rx_eccram_register_error_isr()`

```
rx_err_t rx_eccram_register_error_isr (
    rx_eccram_on_1bit_fn_t on_1bit,
    rx_eccram_on_2bit_fn_t on_2bit,
    void * ctx) [nodiscard]
```

Register user callbacks for ECC error ISRs.

Installs 1-bit and/or 2-bit error callbacks that the driver's ISR trampoline will invoke on the respective RAM-error vectors. Passing nullptr for either callback leaves the previously installed handler in place, allowing callers to register them independently.

Dependency-Injection Rationale (NASA Rule 9 deviation)

Function pointers are permitted here because they are the exact pattern STAR uses to allow test mocks and application-level policy to substitute in without modifying the driver. See CLAUDE.md "SOLID Principles for C / Dependency Inversion".

Parameters

in	on_1bit	Handler invoked from ISR on 1-bit error (may be nullptr).
in	on_2bit	Handler invoked from ISR on 2-bit error (may be nullptr).
in	ctx	Opaque pointer passed through to the handlers.

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Handlers installed.
<code>k_rx_err_invalid_state</code>	rx_eccram_init() has not yet been called.

Precondition

[rx_eccram_init\(\)](#) has been called.

Handlers, if non-null, are safe to call from interrupt context.

Postcondition

The driver's ISR trampolines dispatch to the supplied handlers.

ctx is retained until this function is called again.

Note

Thread Safety: Install once during init before interrupts are enabled, or guard calls at the task level.

Functions

- static volatile `rx_gptw_channel_regs_t` * `internal_get_gptw_base` (const `rx_gptw_channel_t`
channel)
Get GPTW channel register base address.
- static bool `internal_is_triangle_mode` (const `rx_gptw_wave_mode_t` mode)
Check if wave mode is triangle (center-aligned).
- static `uint32_t` `internal_get_gtcr_mode` (const `rx_gptw_wave_mode_t` mode)
Get GTCR mode bits for wave mode.
- static `rx_err_t` `internal_calculate_period` (const `uint32_t` frequency_hz, const `rx_gptw_wave_mode_t`
wave_mode, `uint32_t` *period)
Calculate period register value from frequency.
- static volatile `uint8_t` * `internal_pfs_addr` (`uint8_t` port_idx, `uint8_t` bit)
- static `rx_err_t` `internal_configure_mpc` (const `rx_gptw_config_t` *config)
- static void `internal_configure_port_pins` (const `rx_gptw_config_t` *config)
Configure Port E pins as peripheral outputs.
- static void `internal_enable_gptw_module_clock` (void)
Enable GPTW module clock.
- static `rx_err_t` `internal_configure_gptw_hardware` (volatile `rx_gptw_channel_regs_t` *gptw,
const `rx_gptw_config_t` *config, const `uint32_t` period)

- Configure GPTW hardware registers.
- static rx_err_t [internal_prepare_gptw_pwm_init](#) (const [rx_gptw_channel_t](#) channel, const [rx_gptw_config_t](#) *config, volatile [rx_gptw_channel_regs_t](#) **gptw_out, uint32_t *period_count, rx_err_t *out)
 - Validate channel and compute period for PWM initialization.
- rx_err_t [rx_gptw_init_pwm](#) (const [rx_gptw_channel_t](#) channel, const [rx_gptw_config_t](#) *config)
 - Initialize a single GPTW channel for PWM operation.
- rx_err_t [rx_gptw_set_duty](#) (const [rx_gptw_channel_id_t](#) channel, const [rx_gptw_output_id_t](#) output, const float duty_percent)
 - Set PWM duty cycle using floating-point percentage.
- rx_err_t [rx_gptw_set_duty_raw](#) (const [rx_gptw_channel_t](#) channel, [rx_gptw_output_t](#) output, uint32_t duty_count)
 - Set PWM duty cycle using a raw 32-bit timer count.
- rx_err_t [rx_gptw_get_duty](#) (const [rx_gptw_channel_t](#) channel, const [rx_gptw_output_t](#) output, float *duty_percent)
 - Read the current PWM duty cycle as a floating-point percentage.
- rx_err_t [rx_gptw_get_period](#) (const [rx_gptw_channel_t](#) channel, uint32_t *period_count)
 - Get PWM period count for GPTW channel.
- rx_err_t [rx_gptw_enable_output](#) (const [rx_gptw_channel_t](#) channel, const [rx_gptw_output_t](#) output, bool enable)
 - Enable or disable GPTW output pin.
- rx_err_t [rx_gptw_start](#) (const [rx_gptw_channel_t](#) channel)
 - Start GPTW counter (begin PWM generation).
- rx_err_t [rx_gptw_stop](#) (const [rx_gptw_channel_t](#) channel)
 - Stop GPTW counter (halt PWM generation).
- static void [internal_calculate_phase_offset](#) (const [rx_gptw_channel_t](#) channel, const uint32_t period, const bool is_triangle, uint32_t *init_count, bool *init_dir_up)
 - Calculate initial counter value and direction for phase staggering.
- static rx_err_t [internal_configure_channel_staggered](#) (const [rx_gptw_channel_t](#) channel, const [rx_gptw_config_t](#) *config, const uint32_t period, const bool is_triangle)
 - Configure a single GPTW channel for staggered PWM operation.
- rx_err_t [rx_gptw_init_all_staggered](#) (const [rx_gptw_config_t](#) *configs[k_rx_gptw_channel_count], rx_err_t *out)
 - Initialize all 4 GPTW channels with 90-degree phase staggering.
- rx_err_t [rx_gptw_deinit](#) (const [rx_gptw_channel_t](#) channel)
 - Deinitialize a GPTW channel.

Variables

- static const char *const [s_tag](#) = "GPTW"
- static const uint32_t [s_gptw_period_max](#) = 0xFFFFFFFFFUL
 - Period calculation constants.
- static const uint64_t [s_gptw_ns_per_second](#) = 1000000000ULL
- static bool [s_gptw_initialized](#) [k_gptw_max_channels] = {false}
 - Track initialized channels.
- static uint32_t [s_gptw_period](#) [k_gptw_max_channels] = {}
 - Period values for each channel.

8.117.1 Detailed Description

GPTW PWM Driver Implementation for Motor Control.

Production-grade implementation of the General PWM Timer (GPTW) driver for RX72N motor control applications. This file contains all internal helper functions and public API implementations for GPTW peripheral management.

8.117.1.1 Module Architecture

The implementation is structured in three layers:

1. Constants & Configuration: Typed enums for all magic numbers
2. Internal Helpers: Register access, calculations, hardware configuration
3. Public API: User-facing functions documented in [rx_gptw.h](#)

8.117.1.2 Supported PWM Modes

1. Sawtooth-wave PWM (edge-aligned):

- Counter: 0 -> GTPR -> 0 (reset at top)
- Period = PCLKA / frequency
- For 20kHz: period = 120MHz / 20kHz = 6000 counts (~12.5-bit resolution)
- Single update point at counter reset
- Best for: Simple PWM, LED dimming

2. Triangle-wave PWM (center-aligned):

- Counter: 0 -> GTPR -> 0 (up/down counting)
- Period = PCLKA / (2 x frequency)
- For 20kHz: period = 120MHz / 40kHz = 3000 counts (~11.5-bit resolution)
- Update at crest and/or trough (mode dependent)
- Lower EMI due to symmetric switching edges
- Reduced current ripple in motor windings
- Best for: Motor control with H-bridge

8.117.1.3 Implementation Notes

Register Access Pattern: All GPTW register modifications follow this sequence:

1. Unlock write protection (GTWP = 0xA500_0000)
2. Modify registers
3. Lock write protection (GTWP = 0x0000_0001)

Phase Staggering Implementation: For 4-motor systems, channels are initialized with counter offsets:

- Ch0: GTCNT = 0 (0deg reference)
- Ch1: GTCNT = period/4 (90deg offset)
- Ch2: GTCNT = period/2 (180deg offset)
- Ch3: GTCNT = 3xperiod/4 (270deg offset)

8.117.1.4 Memory Map

GPTW Register Base Addresses:

Module	Base Address	Size	Description
GPTW Common	0x000C2000	0x100	Shared start/stop registers
GPTW0	0x000C2100	0x80	Channel 0 registers
GPTW1	0x000C2180	0x80	Channel 1 registers
GPTW2	0x000C2200	0x80	Channel 2 registers
GPTW3	0x000C2280	0x80	Channel 3 registers

Module Clock:

- MSTPCRA.MSTPA7 controls GPTW module clock on RX72N
- Must be cleared (= 0) before register access
- Protected by PRCR register lock (PRC1, key 0xA502)

Clock Assumption:

This driver assumes PCKA = 96 MHz, which matches the STAR firmware clock_init: HOCO 16 MHz x12 PLL = 192 MHz, SCKCR=0x21C21211 giving PCKA = PLL/2 = 96 MHz. At 20 kHz PWM this yields GTPR = 96M/20k - 1 = 4799. If the board ever moves to a different clock plan the HAL must be updated (k_pclka_hz in [rx72n_clock.h](#)).

8.117.1.5 Static Variables

Variable	Type	Purpose
s_gptw_ initialized[]	bool [4]	Track which channels are initialized
s_gptw_ period[]	uint32_t [4]	Cache period values for duty calculation
s_tag	const char*	Log tag "GPTW"

NASA Power of 10 Compliance:

Rule	Status	Implementation
1. Simple control flow	 [OK]	No goto/setjmp/recursion in any function
2. Fixed loop bounds	 [OK]	Loops bounded by k_gptw_max_channels (4)
3. No dynamic allocation	 [OK]	All variables static or stack, zero malloc
4. Small functions	 [OK]	All functions < 60 lines
5. Assertions	 [OK]	RX_CHECK_NULL_PTR, switch validation, range checks
6. Narrow scope	 [OK]	Internal functions use static, minimal globals
7. Check return values	 [OK]	All rx_err_t returns propagated or handled
8. Limited preprocessor	 [OK]	C23 typed enums, macros only for RX_CHECK
9. Pointer restrictions	 [OK]	Single-level pointers, no function pointers
10. Compiler warnings	 [OK]	Builds clean with -Wall -Wextra -Werror

SOLID Principles:

Single Responsibility: This file handles ONLY GPTW hardware abstraction. Motor control logic, PID calculations, and H-bridge configuration are in separate modules.

Open/Closed: New waveform modes can be added by extending the [rx_gptw_wave_mode_t](#) enum and [internal_get_gtcr_mode\(\)](#) without modifying existing code paths.

00151  k_gptw_period_min        = 10, /**< Minimum valid period */
00152  k_gptw_period_zero       = 0, /**< Zero period value */
00153  k_gptw_deadtime_disabled = 0, /**< No dead time */
00154 } gptw_period_constants_t;
```

8.117.2.7 gptw`phase`divisor`

enum [gptw_phase_divisor_t](#) : uint8_t

Phase divisors for staggered PWM initialization.

Divisor constants used to calculate the initial GTCNT counter value for each GPTW channel during staggered initialization. Each channel is offset by 90 degrees from the previous one to spread switching edges across the PWM period.

For a given period P the offsets are:

- Ch0: 0 (0/4 of P)
- Ch1: P / 4 (quarter divisor)
- Ch2: P / 2 (half divisor)
- Ch3: 3 * P / 4 (three-quarter: multiply by 3, then divide by 4)

Invariant

All divisor values are ≥ 1 , preventing division-by-zero in [internal_calculate_phase_offset\(\)](#)

```
// Example: derive 90-degree offset for a period of 3000 counts
uint32_t offset_ch1 = 3000U / k_phase_divisor_quarter; // == 750
uint32_t offset_ch3 = (3000U * 3U) / k_phase_divisor_three_quarter; // == 2250
```

See also

[internal_calculate_phase_offset\(\)](#) Uses these divisors for GTCNT seeding

Enumerator

k_phase_divisor_none	0 deg: no offset (safe default, never causes div-by-zero)
k_phase_divisor_quarter	90 deg = period/4
k_phase_divisor_half	180 deg = period/2
k_phase_divisor_three_quarter	270 deg = 3*period/4 (multiplied by 3 then divided)

Definition at line 1459 of file [rx_gptw.c](#).

```
01459         : uint8_t {
01460   k_phase_divisor_none    = 1, /**< 0 deg: no offset (safe default, never causes div-by-zero) */
01461   k_phase_divisor_quarter = 4, /**< 90 deg = period/4 */
01462   k_phase_divisor_half    = 2, /**< 180 deg = period/2 */
01463   k_phase_divisor_three_quarter = 4, /**< 270 deg = 3*period/4 (multiplied by 3 then divided) */
01464 } gptw_phase_divisor_t;
```

8.117.2.8 mpc`pfs`offset`constants`t

```
enum mpc\_pfs\_offset\_constants\_t : uint16_t
```

MPC PFS register offset constants.

Enumerator

k_mpc_pfs_base_offset	Base offset for PFS registers
k_mpc_port_e_index	Port E index
k_mpc_pfs_port_stride	Bytes between port PFS groups

Definition at line 171 of file [rx_gptw.c](#).

```
00171         : uint16_t {
00172   k_mpc_pfs_base_offset = 0x40, /**< Base offset for PFS registers */
00173   k_mpc_port_e_index    = 0x0E, /**< Port E index */
00174   k_mpc_pfs_port_stride = 8,    /**< Bytes between port PFS groups */
00175 } mpc_pfs_offset_constants_t;
```

8.117.2.9 mpc`pwpr`constants`t

```
enum mpc\_pwpr\_constants\_t : uint8_t
```

MPC configuration constants.

Enumerator

k_mpc_pwpr_b0wi_clear	Clear B0WI to enable PFSWE write
k_mpc_pwpr_pfswe_set	Set PFSWE to enable PFS write
k_mpc_pwpr_lock	Set B0WI to lock PFS

Definition at line 164 of file `rx_gptw.c`.

```
00164      : uint8_t {
00165  k_mpc_pwpr_b0wi_clear = 0x00, /**< Clear B0WI to enable PFSWE write */
00166  k_mpc_pwpr_pfswe_set  = 0x40, /**< Set PFSWE to enable PFS write */
00167  k_mpc_pwpr_lock       = 0x80, /**< Set B0WI to lock PFS */
00168 } mpc_pwpr_constants_t;
```

8.117.2.10 pfs`block`layout`t

```
enum pfs_block_layout_t : uintptr_t
```

Configure MPC for GPTW output pins.

Configures the Multi-Function Pin Controller (MPC) to route GPTW timer outputs to the appropriate Port E pins. Each GPTW channel uses two pins for complementary PWM outputs (GTIOCA and GTIOCB).

8.117.2.11 MPC Configuration Sequence

1. Clear PWPR.B0WI to enable PFSWE bit access
2. Set PWPR.PFSWE to enable PFS register writes
3. Write PSEL value (0x1E) to select GPTW function for each pin
4. Set PWPR.B0WI to lock PFS registers

8.117.2.12 Pin Assignments

Channel	Output A (GTIOCA)	Output B (GTIOCB)	PSEL
GPTW0	PE5	PE2	0x1E
GPTW1	PE4	PE1	0x1E
GPTW2	PE3	PE0	0x1E
GPTW3	PE7	PE6	0x1E

Precondition

MPC module accessible (no separate clock enable required)

Pins not in use by other peripherals

Postcondition

Port E PFS registers configured for GPTW function
MPC write protection re-enabled

Invariant

MPC write protection always re-locked on exit (success or failure)

Note

Modifies global MPC registers, not thread-safe
Must be called before enabling port pin peripheral mode

Warning

Overwrites any previous pin function assignment
MPC must be unlocked before calling; function handles locking

Performance:

- Execution time: ~20 cycles (register writes)
- Memory: 0 bytes heap, ~8 bytes stack

00201 k_porte_gptw3_b = 6, /**< PE6/GTIOC3B - Motor 3 enable */
00202 } porte_gptw_pin_t;

```

8.117.3 Function Documentation

8.117.3.1 internal_calculate_period()

```

rx_err_t internal_calculate_period (
    const uint32_t frequency_hz,
    const rx\_gptw\_wave\_mode\_t wave_mode,
    uint32_t * period) [static]

```

Calculate period register value from frequency.

Converts a desired PWM frequency to the GTPR (period register) count value. The calculation differs based on waveform mode:

8.117.3.2 Mathematical Formulas

Sawtooth (edge-aligned) mode:

$$\text{period} = \frac{f_{PCLKA}}{f_{PWM}}$$

Triangle (center-aligned) mode:

$$\text{period} = \frac{f_{PCLKA}}{2 \times f_{PWM}}$$

Where:

- f_{PCLKA} = 120 MHz (peripheral clock A)
- f_{PWM} = desired PWM frequency

8.117.3.3 Algorithm Steps

1. Validate period output pointer (RX_CHECK_NULL_PTR)
2. Validate wave_mode via exhaustive switch statement
3. Determine divisor based on mode (1 for sawtooth, 2 for triangle)
4. Check frequency_hz is non-zero (prevent division by zero)
5. Calculate period using 64-bit arithmetic to prevent overflow
6. Validate period is within hardware limits [10, 0xFFFFFFFF]
7. Store result and return success

8.117.3.4 Example Calculations

Frequency	Mode	Period Count	Resolution
20 kHz	Sawtooth	6000	0.0167%
20 kHz	Triangle	3000	0.0333%
100 Hz	Sawtooth	1,200,000	0.000083%
1 MHz	Sawtooth	120	0.833%

Precondition

PCLKA configured to 120 MHz (system clock setup complete)
 period pointer must point to valid uint32_t storage

Postcondition

On success, *period contains valid count [10, 0xFFFFFFFF]
 On failure, *period is unchanged

Invariant

period $\geq$ k_gptw_period_min (10) on success
 Calculation uses 64-bit math to prevent overflow

Note

Thread-safe: No shared state modified
 Uses RX_CHECK_NULL_PTR macro for pointer validation

Warning

Very low frequencies (< 1 Hz) may overflow 32-bit period
 Very high frequencies (> 12 MHz) produce periods < 10 (rejected)

Performance:

- Execution time: ~ 50 cycles (64-bit division)
- Memory: 0 bytes heap, ~ 16 bytes stack

NASA Power of 10 Compliance:

- Rule 5: [OK] 2 preconditions (NULL check, wave_mode validation)
- Rule 7: [OK] Returns error code, no silent failures

Here is the call graph for this function:

Here is the caller graph for this function:

8.117.3.5 internal_calculate_phase_offset()

```

void internal_calculate_phase_offset (
    const rx_gptw_channel_t channel,
    const uint32_t period,
    const bool is_triangle,
    uint32_t * init_count,
    bool * init_dir_up) [static]

```

Calculate initial counter value and direction for phase staggering.

Computes the initial counter value (GTCNT) and counting direction for a GPTW channel to achieve the desired phase offset. Phase staggering spreads PWM edges across the period to reduce peak current draw and EMI.

8.117.3.6 Phase Offset Table (Sawtooth Mode)

Channel	Phase	Counter Init	Direction
Ch0	0deg	0	Up (n/a)
Ch1	90deg	$\text{period} / \frac{1}{4}$	Up (n/a)
Ch2	180deg	$\text{period} / \frac{1}{2}$	Up (n/a)
Ch3	270deg	$3 \times \text{period} / \frac{1}{4}$	Up (n/a)

8.117.3.7 Phase Offset Table (Triangle Mode)

Channel	Phase	Counter Init	Direction
Ch0	0deg	0	Up
Ch1	90deg	$\text{period} / \frac{1}{2}$	Up
Ch2	180deg	period	Down
Ch3	270deg	$\text{period} / \frac{1}{2}$	Down

Precondition

Output pointers must be non-NULL

period should be > 0 for valid calculations

Postcondition

*init_count contains phase offset value

*init_dir_up contains initial direction (triangle mode)

Safe defaults (0, true) on any validation failure

Note

Returns void - validation failures produce safe defaults silently

For sawtooth mode, direction is ignored (always up)

NASA Power of 10 Compliance:

- Rule 5: [OK] nullptr checks, period validation
- Rule 2: [OK] No loops (direct calculation)

Referenced by [internal_configure_channel_staggered\(\)](#).

Here is the caller graph for this function:

8.117.3.8 `internal_configure_channel_staggered()`

```

rx_err_t internal_configure_channel_staggered (
    const rx_gptw_channel_t channel,
    const rx_gptw_config_t * config,
    const uint32_t period,
    const bool is_triangle) [static]

```

Configure a single GPTW channel for staggered PWM operation.

Performs complete hardware configuration for one GPTW channel including base timer setup, MPC pin function selection, port configuration, and phase staggering initialization.

8.117.3.9 Configuration Sequence

1. Validate channel range [0-3]
2. Get channel register base address
3. Configure base hardware (GTCR, GTIOR, GTPR, etc.)
4. Configure MPC for Port E alternate function
5. Configure port pins (PMR, PDR)
6. Calculate phase offset for this channel
7. Set initial counter value (GTCNT)
8. For triangle mode: seed initial count direction
9. Update initialization tracking state

8.117.3.10 Phase Staggering

Counter is initialized to a phase-offset value:

- Ch0: 0deg (reference, GTCNT=0)
- Ch1: 90deg (GTCNT=period/4)
- Ch2: 180deg (GTCNT=period/2)
- Ch3: 270deg (GTCNT=3xperiod/4)

Precondition

Module clock enabled
 Timer stopped
 config pointer valid (caller validates)

Postcondition

Channel fully configured with phase offset
`s_gptw_initialized[channel] = true`
`s_gptw_period[channel] = period`
 Timer NOT started (caller starts all channels together)

Note

Not thread-safe: modifies hardware registers and shared state arrays (`s_gptw_initialized`, `s_gptw_↵_period`); caller must ensure exclusive access
 Timer is NOT started by this function
 Called from `rx_gptw_init_all_staggered()` in a loop

NASA Power of 10 Compliance:

- Rule 5: [OK] Channel range validation
- Rule 7: [OK] All internal function returns checked

Here is the call graph for this function:

Here is the caller graph for this function:

8.117.3.11 internal`configure`gptw`hardware()

```

rx_err_t internal_configure_gptw_hardware (
    volatile rx_gptw_channel_regs_t * gptw,
    const rx_gptw_config_t * config,
    const uint32_t period) [static]

```

Configure GPTW hardware registers.

Performs the core hardware configuration of a GPTW channel. This function writes all necessary registers to set up PWM operation including control mode, I/O configuration, period, duty cycle initialization, buffer mode, and deadline.

8.117.3.12 Register Configuration Sequence

1. Unlock write protection: GTWP = 0xA500_0000
2. Configure control register (GTCR):
 - Set clock source to PCLKA/1 (120 MHz)
 - Set waveform mode (sawtooth or triangle)
3. Configure I/O control (GTIOR):
 - Output A: Initial low, toggle on compare match, enable
 - Output B: Initial low, toggle on compare match, enable

4. Set period register (GTPR): PWM cycle count
5. Initialize duty cycles (GTCCRA, GTCCRB): Both to 0
6. Clear counter (GTCNT): Start at 0
7. Enable buffer operation (GTBER): Glitch-free updates
8. Configure deadtime (GTDVU, GTDVD, GTDTCR): If requested
9. Lock write protection: GTWP = 0x0000_0001

8.117.3.13 Deadtime Calculation

$$\text{deadtime_counts} = \frac{\text{deadtime_ns} \times f_{PCLKA}}{10^9}$$

For 1000 ns at 96 MHz: deadtime_counts = 96

Precondition

gptw points to valid, unlocked GPTW registers
 config contains validated parameters
 period calculated and validated by [internal_calculate_period\(\)](#)

Postcondition

GPTW channel configured for PWM operation
 Duty cycles initialized to 0% (motor stopped)
 Buffer mode enabled for glitch-free updates
 Write protection re-enabled

Invariant

Write protection always re-locked on exit
 Duty cycles always start at 0 (safe state)

Note

Not thread-safe: Direct hardware register access
 Timer is NOT started by this function

Warning

gptw pointer must be valid - no runtime bounds checking
 Caller responsible for stopping timer before calling

Performance:

- Execution time: ~100 cycles (multiple register writes)
- Memory: 0 bytes heap, ~16 bytes stack

NASA Power of 10 Compliance:

- Rule 5: [OK] 3 preconditions (NULL checks, period range)

8.117.3.15 internal`configure`port`pins()

```
void internal_configure_port_pins (
    const rx\_gptw\_config\_t * config) [static]
```

Configure Port E pins as peripheral outputs.

Configures the Port E GPIO pins for GPTW peripheral output mode. Sets both the Peripheral Mode Register (PMR) and Port Direction Register (PDR) to enable GPTW timer outputs.

8.117.3.16 Register Configuration

For each pin used by the specified channel:

- PMR bit = 1: Enable peripheral mode (not GPIO)
- PDR bit = 1: Set pin direction to output

8.117.3.17 Pin Mapping

Channel	Output A Pin	Output B Pin
GPTW0	PE5 (bit 5)	PE2 (bit 2)
GPTW1	PE4 (bit 4)	PE1 (bit 1)
GPTW2	PE3 (bit 3)	PE0 (bit 0)
GPTW3	PE7 (bit 7)	PE6 (bit 6)

Precondition

MPC configured for GPTW function via [internal_configure_mpc\(\)](#)
 config->port_a_idx / config->port_b_idx are valid for [rx_port_get_base\(\)](#)

Postcondition

PMR bits set for both channel pins

PDR bits set for both channel pins

Note

No return value - silent no-op on invalid channel

Modifies Port E registers, not thread-safe

Uses OR-equals to preserve other pin configurations

Performance:

- Execution time: ~10 cycles (register read-modify-write)
- Memory: 0 bytes heap, 0 bytes stack

8.117.3.18 `internal_enable_gptw_module_clock()`

```
void internal_enable_gptw_module_clock (
    void ) [static]
```

Enable GPTW module clock.

Enables the GPTW peripheral by clearing its module stop bit in MSTPCRA. On RX72N, GPTW is controlled by MSTPCRA bit 7 (MSTPA7), per the RX72N Hardware Manual Chapter 11 and Renesas iodef.h. When set, the module clock is stopped and registers are inaccessible.

8.117.3.19 Register Access Sequence

1. Unlock PRCR: Write 0xA502 (PRC1) to enable writing to MSTPCR group
2. Clear MSTPA7: AND-mask to clear bit 7 in MSTPCRA (0x00080010)
3. Lock PRCR: Write 0xA500 to re-enable protection

8.117.3.20 Module Stop Control

Bit	Value	Effect
MSTPCRA.MSTPA7 = 1	Module stopped	Registers inaccessible, low power
MSTPCRA.MSTPA7 = 0	Module running	Registers accessible, clock active

Precondition

System clock configured

Postcondition

GPTW module clock enabled
 GPTW registers accessible
 PRCR protection re-enabled

Invariant

PRCR always re-locked after modification

Note

Not thread-safe: Modifies system-wide registers
 Idempotent: Safe to call multiple times

Warning

Must be called before any GPTW register access
 Modifies system protection register (PRCR)

Performance:

- Execution time: ~15 cycles (3 register writes)
- Memory: 0 bytes heap, 0 bytes stack

8.117.3.21 internal`get`gptw`base()

```
volatile rx_gptw_channel_regs_t * internal_get_gptw_base (
    const rx_gptw_channel_t channel) [static]
```

Get GPTW channel register base address.

Maps a GPTW channel enumeration value to its corresponding hardware register base address. Each GPTW channel (0-3) has a dedicated register block at a fixed memory offset.

8.117.3.22 Memory Map

Channel	Base Address	Offset from GPTW0
k_gptw_channel_0	0x000C2100	0x000
k_gptw_channel_1	0x000C2180	0x080
k_gptw_channel_2	0x000C2200	0x100
k_gptw_channel_3	0x000C2280	0x180

Precondition

Module clock must be enabled before accessing returned pointer

Postcondition

Returned pointer is valid for hardware register access

No hardware state modified by this function

Note

Thread-safe: Returns constant address, no state modification

Caller must check for nullptr before using returned pointer

Performance:

- Execution time: ~10 cycles (switch statement)
- Memory: 0 bytes heap, 0 bytes stack allocation

Here is the call graph for this function:

Here is the caller graph for this function:

8.117.3.23 internal`get`gtcr`mode()

```

uint32_t internal_get_gtcr_mode (
    const rx_gptw_wave_mode_t mode) [static]

```

Get GTCR mode bits for wave mode.

Converts a waveform mode enumeration to the corresponding GTCR.MD register bit field value. The MD field (bits 18:16) in GTCR controls the timer's counting mode and PWM generation behavior.

8.117.3.24 GTCR.MD Field Mapping

Input Mode	GTCR.MD Value	Binary	Description
k_gptw_wave_saw_pwm	k_gptw_gtcr_md_saw_pwm	0b000	Sawtooth PWM
k_gptw_wave_tri_pwm1	k_gptw_gtcr_md_tri_pwm1	0b100	Triangle PWM 1
k_gptw_wave_tri_pwm2	k_gptw_gtcr_md_tri_pwm2	0b101	Triangle PWM 2
k_gptw_wave_tri_pwm3	k_gptw_gtcr_md_tri_pwm3	0b110	Triangle PWM 3

Precondition

mode should be validated before calling (caller's responsibility)
 GTCR write protection must be unlocked before writing returned value

Postcondition

No state modification (pure function)
 Returned value is ready for GTCR register write

Invariant

Invalid modes always return sawtooth as safe fallback

Note

Assert triggers on invalid mode in debug builds
 Returns safe default (sawtooth) on invalid mode in release builds
 Thread-safe: Pure function with no shared state

Warning

RX_ASSERT fires if mode is not a valid enum value

Performance:

- Execution time: ~10 cycles (switch statement)
- Memory: 0 bytes heap, 0 bytes stack

NASA Power of 10 Compliance:

- Rule 5: [OK] RX_ASSERT validates unexpected conditions

Here is the caller graph for this function:

8.117.3.25 `internal_is_triangle_mode()`

```

bool internal_is_triangle_mode (
    const rx\_gptw\_wave\_mode\_t mode)    [inline], [static]
```

Check if wave mode is triangle (center-aligned).

Determines whether the specified waveform mode uses triangle wave (center-aligned) PWM generation. Triangle modes count up to period, then down to zero, resulting in symmetric PWM pulses centered within each period.

8.117.3.26 Mode Classification

Mode	Type	Returns
<code>k_gptw_wave_saw_pwm</code>	Sawtooth (edge-aligned)	false
<code>k_gptw_wave_tri_pwm1</code>	Triangle (center-aligned)	true
<code>k_gptw_wave_tri_pwm2</code>	Triangle (center-aligned)	true
<code>k_gptw_wave_tri_pwm3</code>	Triangle (center-aligned)	true

Precondition

mode should be a valid [rx_gptw_wave_mode_t](#) value

Postcondition

No state modification

Note

Pure function: Same input always produces same output

Thread-safe: No shared state access

Inlined for performance in period calculation loop

Performance:

- Execution time: ~ 3 cycles (two comparisons)
- Inlined at call site, no function call overhead

8.117.3.28 `internal`prepare`gptw`pwm`init()`

```
rx_err_t internal_prepare_gptw_pwm_init (
    const rx_gptw_channel_t channel,
    const rx_gptw_config_t * config,
    volatile rx_gptw_channel_regs_t ** gptw_out,
    uint32_t * period_out)    [static]
```

Validate channel and compute period for PWM initialization.

Shared pre-initialization helper used by `rx_gptw_init_pwm()`. Performs two actions in a single function to reduce code duplication:

1. Validate channel range and resolve register base pointer
2. Calculate the GTPR period value from frequency and wave mode

Precondition

`*gptw_out` and `period_out` must be non-NULL (caller's responsibility)
`config` must be non-NULL (caller's responsibility)

Postcondition

`*gptw_out` points to valid GPTW channel registers on success
`*period_out` contains a value in `[k_gptw_period_min, s_gptw_period_max]` on success

Note

Pure helper: does not modify hardware registers or module state

Not thread-safe: relies on config content stability during call

8.117.3.29 rx`gptw`deinit()

```
rx_err_t rx_gptw_deinit (  
    const rx_gptw_channel_t channel)  [nodiscard]
```

Deinitialize a GPTW channel.

Deinitialize a GPTW channel and release all resources.

Stops the timer, disables both PWM outputs (A and B), and resets the counter to zero. Call only when motor control is no longer active.

Precondition

Motor using this channel must be stopped before calling
channel must be in range [k_gptw_channel_0, k_gptw_channel_3]

Postcondition

Timer counter stopped (GTCR.CST = 0)
Both outputs disabled (GTIOR.OAE = 0, GTIOR.OBE = 0)
Counter register zeroed (GTCNT = k_gptw_period_zero)

Invariant

Write protection re-locked (GTWP) on all exit paths

Note

Not thread-safe: modifies hardware registers directly
Does not clear s_gptw_initialized[] or s_gptw_period[]

Warning

Ensure motor is at rest before calling to prevent abrupt stop

```
rx_err_t err = rx_gptw_deinit(k_gptw_channel_0);
```

8.117.3.30 rx_gptw_enable_output()

```

rx_err_t rx_gptw_enable_output (
    const rx_gptw_channel_t channel,
    const rx_gptw_output_t output,
    bool enable) [nodiscard]

```

Enable or disable GPTW output pin.

Enable or disable a PWM output pin.

Implementation of [rx_gptw_enable_output\(\)](#) - see [rx_gptw.h](#) for complete documentation.

Controls the Output Enable bits (OAE/OBE) in the GTIOR register. When disabled, the corresponding output pin is held in its initial state (typically LOW).

8.117.3.31 Register Modification

Output	Bit Modified	Effect
Output A	GTIOR.OAE	Enable/disable GTIOCnA pin
Output B	GTIOR.OBE	Enable/disable GTIOCnB pin

Precondition

Channel initialized via rx_gptw_init_*()

Postcondition

GTIOR.OAE or GTIOR.OBE modified

Write protection re-enabled

Note

Not thread-safe: Modifies hardware registers

Timer continues running even when output disabled

Warning

Disable outputs before motor emergency stop to ensure safe state

8.117.3.32 rx_gptw_get_duty()

```

rx_err_t rx_gptw_get_duty (
    const rx_gptw_channel_t channel,
    const rx_gptw_output_t output,
    float * duty_percent) [nodiscard]

```

Read the current PWM duty cycle as a floating-point percentage.

Get current duty cycle as a floating-point percentage.

Reads the current compare register value (GTCCRA or GTCCRB) from hardware and converts it to a percentage using the cached period from `s_gptw_period[]`.

Algorithm:

$$\text{duty_percent} = \frac{\text{duty_count} \times 100}{\text{period}}$$

Precondition

- Channel must be initialized via `rx_gptw_init_*`
- `duty_percent` must point to valid float storage

Postcondition

- `*duty_percent` contains duty cycle in `[0.0, 100.0]` on success
- Hardware registers unchanged

Note

Returns actual register value; may differ from the last set value if buffer transfer has not yet occurred at period boundary

Not thread-safe: concurrent `rx_gptw_set_duty` calls may cause torn reads

```
float duty;
rx_err_t err = rx_gptw_get_duty(k_gptw_channel_0, k_gptw_output_a, &duty);
```

    uint32_t * period_count)  [nodiscard]
```

Get PWM period count for GPTW channel.

Get the 32-bit PWM period count for a GPTW channel.

Implementation of [rx_gptw_get_period\(\)](#) - see [rx_gptw.h](#) for complete documentation.

Returns the cached period value from `s_gptw_period[]`, which matches the GTPR register value set during initialization.

Precondition

Channel initialized via `rx_gptw_init_*`()
`period_count` points to valid `uint32_t` storage

Postcondition

`*period_count` contains period value on success

Note

Thread-safe: Reads from cached value, not hardware
 Useful for calculating raw duty counts from percentages

8.117.3.34 rx_gptw_init_all_staggered()

```
rx_err_t rx_gptw_init_all_staggered (
    const rx_gptw_config_t * configs[k_rx_gptw_channel_count])  [nodiscard]
```

Initialize all 4 GPTW channels with 90-degree phase staggering.

Implementation of [rx_gptw_init_all_staggered\(\)](#) - see [rx_gptw.h](#) for complete documentation with diagrams, examples, and NASA compliance notes.

8.117.3.35 Implementation Overview

1. Validate inputs: NULL check, frequency > 0, valid wave_mode
2. Enable module clock: Clear MSTPCRA.MSTPA7
3. Stop all channels: Atomic stop via GTSTPA register
4. Calculate period: Common period for all channels
5. Configure each channel: Loop calls [internal_configure_channel_staggered\(\)](#)
6. Start all channels: Atomic start via GTSTRA register

8.117.3.36 Phase Staggering Benefits

- Reduces peak current by spreading PWM edges across period
- Lowers EMI from simultaneous switching transients
- Allows smaller power supply capacitors

Here is the call graph for this function:

8.117.3.37 rx`gptw`init`pwm()

```

rx_err_t rx_gptw_init_pwm (
    const rx_gptw_channel_t channel,
    const rx_gptw_config_t * config) [nodiscard]

```

Initialize a single GPTW channel for PWM operation.

Initialize a single GPTW channel for PWM output.

Configures one GPTW channel for PWM generation. This function performs complete hardware setup including module clock enable, MPC configuration, port pin setup, timer configuration, and automatic timer start. For 4-motor systems, prefer [rx_gptw_init_all_staggered\(\)](#) instead.

8.117.3.38 Initialization Sequence

1. Validate config pointer (RX_CHECK_NULL_PTR)
2. Validate channel range [0-3]
3. Get channel register base address
4. Calculate period from frequency and wave mode
5. Enable GPTW module clock (MSTPCRA.MSTPA7)
6. Stop timer if already running
7. Configure GPTW hardware registers (GTCR, GTIOR, GTPR, etc.)
8. Configure MPC for Port E alternate function
9. Configure port pins (PMR, PDR)
10. Store period value and set initialized flag
11. Start timer

Precondition

System clock configured (PCLKA = 120 MHz)
Port E pins not used by other peripherals

Postcondition

GPTW channel configured and running
Duty cycle initialized to 0%
MPC and port pins configured

Invariant

s_gptw_initialized[channel] == true on success
s_gptw_period[channel] contains valid period on success

Note

Not thread-safe: Call once during system initialization
Timer starts automatically - use [rx_gptw_stop\(\)](#) to halt if needed

Warning

Calling while channel is running will cause glitches

Attention

For 4-motor systems, use [rx_gptw_init_all_staggered\(\)](#) instead

Performance:

- Execution time: ~50 us at 240 MHz
- Memory: 0 bytes heap, ~32 bytes stack

Example (Single Channel for LED PWM):

```
rx_gptw_config_t led_config = {
    .frequency_hz = 1000,
    .deadtime_ns = 0,
    .wave_mode = k_gptw_wave_saw_pwm,
    .enable_complementary = false,
    .invert_polarity = false
};

rx_err_t err = rx_gptw_init_pwm(k_gptw_channel_0, &led_config);
if (err == k_rx_ok) {
    rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
                    rx_gptw_output_id(k_gptw_output_a), 50.0f);
}
```

Here is the call graph for this function:

8.117.3.39 rx'gptw'set'duty()

```

rx_err_t rx_gptw_set_duty (
    const rx_gptw_channel_id_t channel,
    const rx_gptw_output_id_t output,
    const float duty_percent) [nodiscard]

```

Set PWM duty cycle using floating-point percentage.

Set PWM duty cycle (floating-point percentage).

Converts floating-point duty percentage [0.0, 100.0] to raw count value and delegates to [rx_gptw_set_duty_raw\(\)](#) for hardware register update. The compare register (GTCCR or GTCCRB) is written and the change takes effect on the next PWM period boundary (glitch-free via buffer mode).

Algorithm:

$$\text{duty_count} = \left\lfloor \frac{\text{duty_percent} \times \text{period}}{100} \right\rfloor$$

Precondition

Channel must be initialized via `rx_gptw_init_*`()
 duty_percent must be in `[0.0, 100.0]`

Postcondition

Compare register written; change takes effect next period boundary
 Motor output drive updated on next PWM cycle

Note

Not thread-safe: concurrent writes to same output cause undefined behavior

```
rx_gptw_set_duty(rx_gptw_channel_id(k_gptw_channel_0),
                rx_gptw_output_id(k_gptw_output_a), 75.0f);
```

Here is the call graph for this function:

8.117.3.40 rx`gptw`set`duty`raw()

```
rx_err_t rx_gptw_set_duty_raw (
    const rx_gptw_channel_t channel,
    rx_gptw_output_t output,
    uint32_t duty_count) [nodiscard]
```

Set PWM duty cycle using a raw 32-bit timer count.

Set PWM duty cycle using raw counter value.

Directly writes duty_count to the compare register (GTCCRA or GTCCRB). Buffer mode (enabled during init via GTBER) ensures the update takes effect on the next PWM period boundary without glitches. Values exceeding the period are clamped to period (100% duty).

Register Access:

- Output A: Writes to GTCCRA
- Output B: Writes to GTCCRB

Precondition

Channel must be initialized via rx_gptw_init_*

duty_count should be in [0, period] for meaningful duty; higher values clamped

Postcondition

GTCCRA or GTCCRB written with clamped duty_count

Change takes effect at next PWM period boundary

Note

Not thread-safe: concurrent writes to the same register cause undefined behavior

Values exceeding period are silently clamped to period

```
uint32_t period;
rx_gptw_get_period(k_gptw_channel_0, &period);
rx_gptw_set_duty_raw(k_gptw_channel_0, k_gptw_output_a, period / 2U); // 50%
```

8.117.3.41 rx`gptw`start()

```
rx_err_t rx_gptw_start (
    const rx_gptw_channel_t channel) [nodiscard]
```

Start GPTW counter (begin PWM generation).

Start the GPTW timer counter for PWM generation.

Implementation of [rx_gptw_start\(\)](#) - see [rx_gptw.h](#) for complete documentation.

Sets the Count Start (CST) bit in GTCR to begin counter operation. The timer will count according to the configured waveform mode (sawtooth or triangle) and generate PWM output on the enabled pins.

8.117.3.42 Register Access

1. Unlock write protection (GTWP)
2. Set GTCR.CST bit
3. Lock write protection (GTWP)

Precondition

Channel configured via [rx_gptw_init_*](#)() (recommended)

Postcondition

Timer counting actively
PWM output generated on enabled pins

Note

Does NOT require channel to be "initialized" (no flag check)
Timer automatically started during [rx_gptw_init_*](#)()
Idempotent: Safe to call when already running

    const rx_gptw_channel_t channel) [nodiscard]
```

Stop GPTW counter (halt PWM generation).

Stop the GPTW timer counter.

Implementation of `rx_gptw_stop()` - see [rx_gptw.h](#) for complete documentation.

Clears the Count Start (CST) bit in GTCR to halt counter operation. The timer counter value (GTCNT) is preserved and PWM outputs hold their current state.

8.117.3.44 Register Access

1. Unlock write protection (GTWP)
2. Clear GTCR.CST bit
3. Lock write protection (GTWP)

Precondition

None (can be called on uninitialized channel)

Postcondition

Timer stopped (GTCR.CST = 0)
 Counter value preserved (GTCNT unchanged)
 Output pins hold last state

Note

Does NOT require channel to be "initialized" (no flag check)

Idempotent: Safe to call when already stopped

For safety shutdown, also disable outputs via [rx_gptw_enable_output\(\)](#)

Warning

Outputs may remain HIGH when stopped - disable outputs for safe state

See also

[rx_gptw_start\(\)](#) Resume the timer

[rx_gptw_enable_output\(\)](#) Disable outputs for safe state

00001 /**
00002  * @file rx_gptw.c
00003  * @brief GPTW PWM Driver Implementation for Motor Control
00004  *
00005  * @details
00006  * **Production-grade implementation** of the General PWM Timer (GPTW) driver for
00007  * RX72N motor control applications. This file contains all internal helper
00008  * functions and public API implementations for GPTW peripheral management.
00009  *
00010  * ## Module Architecture
00011  *
00012  * The implementation is structured in three layers:
00013  * 1. **Constants & Configuration**: Typed enums for all magic numbers
00014  * 2. **Internal Helpers**: Register access, calculations, hardware configuration
00015  * 3. **Public API**: User-facing functions documented in rx_gptw.h
00016  *
00017  * ## Supported PWM Modes
00018  *
00019  * **1. Sawtooth-wave PWM (edge-aligned)**:
00020  * - Counter: 0 -> GTPR -> 0 (reset at top)
00021  * - Period = PCLKA / frequency
00022  * - For 20kHz: period = 120MHz / 20kHz = 6000 counts (~12.5-bit resolution)
00023  * - Single update point at counter reset
00024  * - Best for: Simple PWM, LED dimming
00025  *
00026  * **2. Triangle-wave PWM (center-aligned)**:
00027  * - Counter: 0 -> GTPR -> 0 (up/down counting)
00028  * - Period = PCLKA / (2 x frequency)
00029  * - For 20kHz: period = 120MHz / 40kHz = 3000 counts (~11.5-bit resolution)
00030  * - Update at crest and/or trough (mode dependent)
00031  * - Lower EMI due to symmetric switching edges
00032  * - Reduced current ripple in motor windings
00033  * - Best for: Motor control with H-bridge
00034  *
00035  * ## Implementation Notes
00036  *
00037  * **Register Access Pattern**:
00038  * All GPTW register modifications follow this sequence:
00039  * 1. Unlock write protection (GTWP = 0xA500_0000)
00040  * 2. Modify registers
00041  * 3. Lock write protection (GTWP = 0x0000_0001)
00042  *
00043  * **Phase Staggering Implementation**:
00044  * For 4-motor systems, channels are initialized with counter offsets:
00045  * - Ch0: GTCNT = 0 (0deg reference)
00046  * - Ch1: GTCNT = period/4 (90deg offset)
00047  * - Ch2: GTCNT = period/2 (180deg offset)
00048  * - Ch3: GTCNT = 3xperiod/4 (270deg offset)
00049  *
00050  * ## Memory Map
00051  *
00052  * @par GPTW Register Base Addresses:
00053  *
00054  * | Module | Base Address | Size | Description |
00055  * |-----|-----|-----|-----|
00056  * | GPTW Common | 0x000C2000 | 0x100 | Shared start/stop registers |
00057  * | GPTW0 | 0x000C2100 | 0x80 | Channel 0 registers |
00058  * | GPTW1 | 0x000C2180 | 0x80 | Channel 1 registers |
00059  * | GPTW2 | 0x000C2200 | 0x80 | Channel 2 registers |
00060  * | GPTW3 | 0x000C2280 | 0x80 | Channel 3 registers |
00061  *
00062  * @par Module Clock:
00063  * - MSTPCRA.MSTPA7 controls GPTW module clock on RX72N
00064  * - Must be cleared (= 0) before register access
00065  * - Protected by PRCR register lock (PRC1, key 0xA502)
00066  *
00067  * @par Clock Assumption:
00068  * This driver assumes PCKA = 96 MHz, which matches the STAR firmware
00069  * clock_init: HOCO 16 MHz x12 PLL = 192 MHz, SCKCR=0x21C21211 giving
00070  * PCKA = PLL/2 = 96 MHz. At 20 kHz PWM this yields GTPR = 96M/20k - 1 = 4799.
00071  * If the board ever moves to a different clock plan the HAL must be
00072  * updated (k_pclka_hz in rx72n_clock.h).
00073  *
00074  * ## Static Variables
00075  *
00076  * | Variable | Type | Purpose |
00077  * |-----|-----|-----|
00078  * | s_gptw_initialized[] | bool[4] | Track which channels are initialized |
00079  * | s_gptw_period[] | uint32_t[4] | Cache period values for duty calculation |
00080  * | s_tag | const char* | Log tag "GPTW" |
00081  *
00082  * @par NASA Power of 10 Compliance:

```

```

00083 *
00084 * | Rule | Status | Implementation |
00085 * |-----|-----|-----|
00086 * | 1. Simple control flow | [OK] | No goto/setjmp/recursion in any function |
00087 * | 2. Fixed loop bounds | [OK] | Loops bounded by k_gptw_max_channels (4) |
00088 * | 3. No dynamic allocation | [OK] | All variables static or stack, zero malloc |
00089 * | 4. Small functions | [OK] | All functions < 60 lines |
00090 * | 5. Assertions | [OK] | RX_CHECK_NULL_PTR, switch validation, range checks |
00091 * | 6. Narrow scope | [OK] | Internal functions use static, minimal globals |
00092 * | 7. Check return values | [OK] | All rx_err_t returns propagated or handled |
00093 * | 8. Limited preprocessor | [OK] | C23 typed enums, macros only for RX_CHECK |
00094 * | 9. Pointer restrictions | [OK] | Single-level pointers, no function pointers |
00095 * | 10. Compiler warnings | [OK] | Builds clean with -Wall -Wextra -Werror |
00096
00097 * @par SOLID Principles:
00098 *
00099 * **Single Responsibility**: This file handles ONLY GPTW hardware abstraction.
00100 * Motor control logic, PID calculations, and H-bridge configuration are in
00101 * separate modules.
00102 *
00103 * **Open/Closed**: New waveform modes can be added by extending the
00104 * rx_gptw_wave_mode_t enum and internal_get_gtcr_mode() without modifying
00105 * existing code paths.
00106 *
00107 * @see rx_gptw.h Public API documentation
00108 * @see rx72n_gptw_regs.h Register structure definitions
00109 * @see RX72N Hardware Manual Chapter 26 - General PWM Timer (GPTW)
00110 * @see docs/sections/03_hardware_pinout.tex Pin assignments
00111 *

00377 * @brief Calculate period register value from frequency
00378 *
00379 * @details
00380 * Converts a desired PWM frequency to the GTPR (period register) count value.
00381 * The calculation differs based on waveform mode:
00382 *
00383 * ## Mathematical Formulas
00384 *
00385 * **Sawtooth (edge-aligned) mode:**
00386 * @f[
00387 * \text{period} = \frac{f_{\text{PCLKA}}}{f_{\text{PWM}}}
00388 * @f]
00389 *
00390 * **Triangle (center-aligned) mode:**
00391 * @f[
00392 * \text{period} = \frac{f_{\text{PCLKA}}}{2 \times f_{\text{PWM}}}
00393 * @f]
00394 *
00395 * Where:
00396 * - @f$ f_{\text{PCLKA}} $ @f$ = 120 MHz (peripheral clock A)
00397 * - @f$ f_{\text{PWM}} $ @f$ = desired PWM frequency
00398 *
00399 * ## Algorithm Steps
00400 *
00401 * 1. Validate period output pointer (RX_CHECK_NULL_PTR)
00402 * 2. Validate wave_mode via exhaustive switch statement
00403 * 3. Determine divisor based on mode (1 for sawtooth, 2 for triangle)
00404 * 4. Check frequency_hz is non-zero (prevent division by zero)
00405 * 5. Calculate period using 64-bit arithmetic to prevent overflow
00406 * 6. Validate period is within hardware limits [10, 0xFFFFFFFF]
00407 * 7. Store result and return success
00408 *
00409 * ## Example Calculations
00410 *
00411 * | Frequency | Mode | Period Count | Resolution |
00412 * |-----|-----|-----|-----|
00413 * | 20 kHz | Sawtooth | 6000 | 0.0167% |
00414 * | 20 kHz | Triangle | 3000 | 0.0333% |
00415 * | 100 Hz | Sawtooth | 1,200,000 | 0.000083% |
00416 * | 1 MHz | Sawtooth | 120 | 0.833% |
00417 *
00418 *
00419 *
00420 * @pre PCLKA configured to 120 MHz (system clock setup complete)
00421 * @pre period pointer must point to valid uint32_t storage
00422 *
00423 * @post On success, *period contains valid count [10, 0xFFFFFFFF]
00424 * @post On failure, *period is unchanged

```

```

00425 *
00426 * @invariant period >= k_gptw_period_min (10) on success
00427 * @invariant Calculation uses 64-bit math to prevent overflow
00428 *
00429 * @note Thread-safe: No shared state modified
00430 * @note Uses RX_CHECK_NULL_PTR macro for pointer validation
00431 *
00432 * @warning Very low frequencies (< 1 Hz) may overflow 32-bit period
00433 * @warning Very high frequencies (> 12 MHz) produce periods < 10 (rejected)
00434 *
00435 * @par Performance:
00436 * - Execution time: ~50 cycles (64-bit division)

00885  * @brief Initialize a single GPTW channel for PWM operation
00886  *
00887  * @details
00888  * Configures one GPTW channel for PWM generation. This function performs complete
00889  * hardware setup including module clock enable, MPC configuration, port pin setup,
00890  * timer configuration, and automatic timer start. For 4-motor systems, prefer
00891  * rx_gptw_init_all_staggered() instead.
00892  *
00893  * ## Initialization Sequence
00894  *
00895  * 1. Validate config pointer (RX_CHECK_NULL_PTR)
00896  * 2. Validate channel range [0-3]
00897  * 3. Get channel register base address
00898  * 4. Calculate period from frequency and wave mode
00899  * 5. Enable GPTW module clock (MSTPCRA.MSTPA7)
00900  * 6. Stop timer if already running
00901  * 7. Configure GPTW hardware registers (GTCR, GTIOR, GTPR, etc.)
00902  * 8. Configure MPC for Port E alternate function
00903  * 9. Configure port pins (PMR, PDR)
00904  * 10. Store period value and set initialized flag
00905  * 11. Start timer
00906  *
00907  *
00908  *
00909  * @pre System clock configured (PCLKA = 120 MHz)
00910  * @pre Port E pins not used by other peripherals
00911  *
00912  * @post GPTW channel configured and running
00913  * @post Duty cycle initialized to 0%
00914  * @post MPC and port pins configured
00915  *
00916  * @invariant s_gptw_initialized[channel] == true on success
00917  * @invariant s_gptw_period[channel] contains valid period on success
00918  *
00919  * @note Not thread-safe: Call once during system initialization
00920  * @note Timer starts automatically - use rx_gptw_stop() to halt if needed
00921  *
00922  * @warning Calling while channel is running will cause glitches
00923  * @attention For 4-motor systems, use rx_gptw_init_all_staggered() instead
00924  *
00925  * @par Performance:
00926  * - Execution time: ~50 us at 240 MHz
00927  * - Memory: 0 bytes heap, ~32 bytes stack
00928  *
00929  * @par Example (Single Channel for LED PWM):
00930  * @code{.c}
00931  * rx_gptw_config_t led_config = {
00932  *     .frequency_hz = 1000,

01601  * @brief Configure a single GPTW channel for staggered PWM operation
01602  *
01603  * @details
01604  * Performs complete hardware configuration for one GPTW channel including
01605  * base timer setup, MPC pin function selection, port configuration, and
01606  * phase staggering initialization.
01607  *
01608  * ## Configuration Sequence
01609  *
01610  * 1. Validate channel range [0-3]
01611  * 2. Get channel register base address
01612  * 3. Configure base hardware (GTCR, GTIOR, GTPR, etc.)
01613  * 4. Configure MPC for Port E alternate function
01614  * 5. Configure port pins (PMR, PDR)
01615  * 6. Calculate phase offset for this channel
01616  * 7. Set initial counter value (GTCNT)
01617  * 8. For triangle mode: seed initial count direction
01618  * 9. Update initialization tracking state
01619  *
01620  * ## Phase Staggering
01621  *
01622  * Counter is initialized to a phase-offset value:
01623  * - Ch0: 0deg (reference, GTCNT=0)
01624  * - Ch1: 90deg (GTCNT=period/4)
01625  * - Ch2: 180deg (GTCNT=period/2)
01626  * - Ch3: 270deg (GTCNT=3xperiod/4)
01627  *
01628  *
01629  *
01630  * @pre Module clock enabled
01631  * @pre Timer stopped
01632  * @pre config pointer valid (caller validates)
01633  *
01634  * @post Channel fully configured with phase offset
01635  * @post s_gptw_initialized[channel] = true
01636  * @post s_gptw_period[channel] = period
01637  * @post Timer NOT started (caller starts all channels together)
01638  *

```

```

```

```

01726 * ## Implementation Overview
01727 *
01728 * 1. **Validate inputs**: NULL check, frequency > 0, valid wave_mode
01729 * 2. **Enable module clock**: Clear MSTPCRA.MSTPA7
01730 * 3. **Stop all channels**: Atomic stop via GTSTPA register
01731 * 4. **Calculate period**: Common period for all channels
01732 * 5. **Configure each channel**: Loop calls internal_configure_channel_staggered()
01733 * 6. **Start all channels**: Atomic start via GTSTRA register
01734 *
01735 * ## Phase Staggering Benefits
01736 *
01737 * - Reduces peak current by spreading PWM edges across period
01738 * - Lowers EMI from simultaneous switching transients
01739 * - Allows smaller power supply capacitors
01740 *
01741 *
01742 *

Enumerations

- enum `host_irq_gpio_constants_t` : `uint8_t { k_host_irq_pin_bit = 7 , k_host_irq_pin_mask = 0x80 , k_host_irq_active = 0 , k_host_irq_idle = 1 }`
GPIO configuration constants for HOST_IRQ on P67.

Functions

- `rx_err_t rx_host_irq_init` (void)
Initialize HOST_IRQ pin as GPIO output (deasserted / HIGH).
- `rx_err_t rx_host_irq_deinit` (void)
Deinitialize the HOST_IRQ output (implementation).
- `rx_err_t rx_host_irq_assert` (void)
Assert the HOST_IRQ line (implementation).
- `rx_err_t rx_host_irq_deassert` (void)
De-assert the HOST_IRQ line (implementation).
- `rx_err_t rx_host_irq_is_asserted` (bool *asserted)
Check if HOST_IRQ is currently asserted.

Variables

- static const char *const `s_tag` = "HOST_IRQ"
- static bool `s_initialized` = false
Initialization flag.

8.119.1 Detailed Description

HOST_IRQ GPIO Output Driver Implementation.

Configures P67 (PORT6 pin 7) as a GPIO output for signaling the RPi5 host controller that the RX72N has data ready for SPI transfer. The pin is active-low: assert LOW = data ready, deassert HIGH = idle.

8.119.1.1 GPIO Configuration

```
rx_host_irq_init()
1. PMR6.B7 = 0    (GPIO mode)
2. PODR6.B7 = 1   (initial HIGH = idle)
3. PDR6.B7 = 1    (output direction)

rx_host_irq_assert()
PODR6.B7 = 0      (drive LOW = data ready)

rx_host_irq_deassert()
PODR6.B7 = 1      (drive HIGH = idle)
```

NASA Power of 10 Compliance:

- Rule 1: No goto, setjmp, recursion
- Rule 3: No dynamic memory (static variables only)
- Rule 4: All functions < 60 lines
- Rule 5: 2+ validation checks per function
- Rule 7: All return values checked
- Rule 8: C23 typed enums, no magic numbers
- Rule 10: -Wall -Wextra -Werror clean

```

8.119.3 Function Documentation

8.119.3.1 rx`host`irq`assert()

```
rx_err_t rx_host_irq_assert (
    void ) [nodiscard]
```

Assert the HOST_IRQ line (implementation).

Assert HOST_IRQ (drive LOW to signal data ready).

Drives the P67 output LOW to signal the host SoC that the RX72N has data ready or wants attention. HOST_IRQ is an active-low, level-triggered line; the host will continue to see "asserted" until [rx_host_irq_deassert\(\)](#) drives it back HIGH. The function is a single register read-modify-write on PORT6.PODR; no interrupts are touched.

Note

Safe to call from task context. Not protected against concurrent calls; serialize at the application layer.

Definition at line 148 of file [rx_host_irq.c](#).

```
00149 {
00150     if (!s_initialized) {
00151         return k_rx_err_invalid_state;
00152     }
00153
00154     volatile rx_port_regs_t* p6 = port6();
00155     p6->podr &= (uint8_t)~k_host_irq_pin_mask;
00156
00157     return k_rx_ok;
00158 }
```

References [k_host_irq_pin_mask](#), [rx_port_regs_t::podr](#), [port6\(\)](#), and [s_initialized](#).

Here is the call graph for this function:

8.119.3.2 rx_host_irq_deassert()

```
rx_err_t rx_host_irq_deassert (
    void ) [nodiscard]
```

De-assert the HOST_IRQ line (implementation).

Deassert HOST_IRQ (drive HIGH, idle state).

Drives the P67 output HIGH to release the active-low HOST_IRQ line back to its idle state. Single register read-modify-write on PORT6.PODR; no interrupts touched.

Note

Safe to call from task context. Not protected against concurrent calls; serialize at the application layer.

Definition at line 171 of file [rx_host_irq.c](#).

```
00172 {
00173     if (!s_initialized) {
00174         return k_rx_err_invalid_state;
00175     }
00176
00177     volatile rx_port_regs_t* p6 = port6();
00178     p6->podr |= k_host_irq_pin_mask;
00179
00180     return k_rx_ok;
00181 }
```

References [k_host_irq_pin_mask](#), [rx_port_regs_t::podr](#), [port6\(\)](#), and [s_initialized](#).

Here is the call graph for this function:

8.119.3.3 rx_host_irq_deinit()

```
rx_err_t rx_host_irq_deinit (
    void ) [nodiscard]
```

Deinitialize the HOST_IRQ output (implementation).

Deinitialize HOST_IRQ pin (revert to input).

Symmetric counterpart to [rx_host_irq_init\(\)](#). Drives P67 high one last time so the line is left in its idle (de-asserted) state, then changes the pin direction back to input, gating off any spurious downstream effects. Clears the `s_initialized` flag so subsequent assert/deassert calls return `k_rx_err_invalid_state`.

Note

Not thread-safe. Serialize all `rx_host_irq_*` operations at the application layer.

Definition at line 114 of file `rx_host_irq.c`.

```

00115 {
00116     if (!s_initialized) {
00117         rx_log_error(s_tag, "Not initialized");
00118         return k_rx_err_invalid_state;
00119     }
00120
00121     volatile rx_port_regs_t* p6 = port6();
00122
00123     /* Deassert before reverting to input */
00124     p6->podr |= k_host_irq_pin_mask;
00125
00126     /* Revert to input (safe default) */
00127     p6->pdr &= (uint8_t)~k_host_irq_pin_mask;
00128
00129     s_initialized = false;
00130
00131     rx_log_info(s_tag, "HOST_IRQ P67 deinitialized (input)");
00132     return k_rx_ok;
00133 }

```

Here is the call graph for this function:

8.119.3.4 rx`host`irq`init()

```

rx_err_t rx_host_irq_init (
    void ) [nodiscard]

```

Initialize HOST_IRQ pin as GPIO output (deasserted / HIGH).

Configures P67 as a GPIO output in CMOS push-pull mode. Sets the initial output level to HIGH (deasserted / idle). The MPC function select is set to GPIO (not IRQ input).

Initialization steps:

1. Clear PMR bit 7 (GPIO mode, not peripheral)
2. Set PODR bit 7 HIGH (deasserted state)
3. Set PDR bit 7 (output direction)

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Success, P67 configured as output
<code>k_rx_err_invalid_state</code>	Already initialized

Precondition

P67 not in use by another peripheral (RIIC2 etc.)

Postcondition

P67 configured as GPIO output, driven HIGH

Note

Not thread-safe. Call during system init only.

8.119.3.5 rx`host`irq`is`asserted()

```
rx_err_t rx_host_irq_is_asserted (
    bool * asserted) [nodiscard]
```

Check if HOST_IRQ is currently asserted.

Returns the current state of the HOST_IRQ output.

Parameters

out	asserted	Pointer to store state (true = asserted / LOW)
-----	----------	--

Returns

rx_err_t Error code

Return values

k_rx_ok	Success
k_rx_err_null_ptr	asserted is nullptr

Precondition

[rx_host_irq_init\(\)](#) called

Postcondition

asserted set to current output state

Note

Thread-safe (reads volatile register)

Functions

- rx_err_t [rx_irq_filter_enable](#) (uint8_t irq_num, [rx_irq_filter_clk_t](#) filter_clk)
Enable hardware digital filter on an IRQ pin.
- rx_err_t [rx_irq_filter_disable](#) (uint8_t irq_num)
Disable hardware digital filter on an IRQ pin.
- rx_err_t [rx_irq_filter_is_enabled](#) (uint8_t irq_num, bool *enabled)
Check if digital filter is enabled on an IRQ pin.
- rx_err_t [rx_irq_filter_get_clock](#) (uint8_t irq_num, [rx_irq_filter_clk_t](#) *filter_clk)
Get current filter clock divisor setting for an IRQ.

8.121.1 Detailed Description

IRQ Digital Filter Driver Implementation for RX72N.

Implements hardware digital filtering on IRQ pins using the ICU (Interrupt Controller Unit) peripheral. The filter provides noise rejection by requiring 3 consecutive samples at the same level before recognizing a valid transition.

Implementation Architecture

Register Organization

```

* IRQFLTE[0] (Filter Enable for IRQ0-7):
* +-----+-----+-----+-----+-----+-----+
* | IRQ7| IRQ6| IRQ5| IRQ4| IRQ3| IRQ2| IRQ1| IRQ0|
* | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
* +-----+-----+-----+-----+-----+-----+
*
* IRQFLTC[0] (Filter Clock for IRQ0-7):
* +-----+-----+-----+-----+-----+-----+
* | IRQ7 | IRQ6 | IRQ5 | IRQ4 | IRQ3 | IRQ2 | IRQ1 | IRQ0 |
* |b15:b14 |b13:b12 |b11:b10 | b9:b8 | b7:b6 | b5:b4 | b3:b2 | b1:b0 |
* +-----+-----+-----+-----+-----+-----+
* Clock values: 00=PCLK/1, 01=PCLK/8, 10=PCLK/32, 11=PCLK/64
*

```

Performance Characteristics

Function	Execution Time	Stack Usage
enable()	~200 ns	8 bytes
disable()	~100 ns	4 bytes
is_enabled()	~80 ns	4 bytes
get_clock()	~100 ns	8 bytes

Memory Usage

Category	Size	Notes
Code (.text)	~200 bytes	All functions
Constants (.rodata)	0 bytes	None
Static data	0 bytes	No static variables

Thread Safety

Not thread-safe. Register read-modify-write operations are not atomic. If filter configuration must change at runtime, use mutex protection.

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, recursion
- Rule 2: [OK] No loops (direct register operations)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] All functions < 30 lines
- Rule 5: [OK] Input validation on all functions
- Rule 7: [OK] All return values checked
- Rule 8: [OK] C23 typed enums for constants
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

8.121.2 Enumeration Type Documentation

8.121.2.1 irq`filter`constants`

enum [irq_filter_constants_t](#) : uint8_t

IRQ filter register organization and bit field constants.

Defines constants for navigating the IRQFLTE and IRQFLTC register arrays. The ICU organizes filter controls into two registers each:

- Index 0: IRQ0-7 (lower 8 IRQs)
- Index 1: IRQ8-15 (upper 8 IRQs)

Register Index Calculation

```
* For IRQ number N:  
* - Register index = N / 8 (0 for IRQ0-7, 1 for IRQ8-15)  
* - Bit position = N % 8 (0-7 within the register)  
* - Clock position = bit_position * 2 (2 bits per IRQ in IRQFLTC)  
*
```

Since

Version 1.0.0

Enumerator

k_irq_filter_irqs_per_reg	Number of IRQs controlled by each register pair. IRQFLTE[0]/↵ IRQFLTC[0] handle IRQ0-7, [1] handles IRQ8-15
k_irq_filter_clock_bits	Number of bits per clock divisor setting in IRQFLTC. Each IRQ uses 2 bits for 4 possible divisor values (0-3)
k_irq_filter_clock_mask	Bit mask for extracting/setting clock divisor value. 2 bits = 0b11 = 0x03

8.121.3 Function Documentation

8.121.3.1 rx_irq_filter_disable()

```

rx_err_t rx_irq_filter_disable (
    uint8_t irq_num) [nodiscard]

```

Disable hardware digital filter on an IRQ pin.

Clears the filter enable bit in IRQFLTE for the specified IRQ. After disabling, raw unfiltered input passes to interrupt detector.

Note

Clock divisor setting preserved for potential re-enable

Here is the call graph for this function:

8.121.3.2 rx`irq`filter`enable()

```
rx_err_t rx_irq_filter_enable (
    uint8_t irq_num,
    rx\_irq\_filter\_clk\_t filter_clk) [nodiscard]
```

Enable hardware digital filter on an IRQ pin.

Configures the ICU filter enable (IRQFLTE) and filter clock (IRQFLTC) registers for the specified IRQ. Sets clock divisor first, then enables the filter to avoid sampling at incorrect rate during transition.

Register Modification Sequence

1. IRQFLTC: Clear and set 2-bit clock field for this IRQ
2. IRQFLTE: Set enable bit for this IRQ

Note

On host (non-RX) builds, validates parameters but skips register access

```

rx_err_t rx_irq_filter_get_clock (
    uint8_t irq_num,
    rx_irq_filter_clk_t * filter_clk) [nodiscard]

```

Get current filter clock divisor setting for an IRQ.

Reads the 2-bit clock divisor field from IRQFLTC register for the specified IRQ. Returns the divisor setting even if filter is disabled.

Note

On host builds, always returns `k_irq_filter_pclk_1`

Enumerations

- enum `iwdt_timeout_limits_t` : `uint32_t` { `k_iwdt_timeout_min_ms` = 1 , `k_iwdt_timeout_max_ms` = 16384 }
IWDT timeout validation limits.
- enum `iwdt_init_state_t` : `uint8_t` { `k_iwdt_not_initialized` = 0 , `k_iwdt_initialized` = 1 }
IWDT initialization state tracking.
- enum `iwdt_buffer_size_constants_t` : `uint8_t` { `k_task_name_max_len` = 16 , `k_task_name_cmp_len` = 15 , `k_log_msg_buffer_size` = 64 }
Task monitoring string buffer size constants.
- enum `task_registration_state_t` : `uint8_t` { `k_task_not_registered` = 0 , `k_task_registered` = 1 }
Task registration state tracking.
- enum `task_search_constants_t` : `int32_t` { `k_task_not_found` = -1 , `k_task_idx_min` = 0 }
Constants for task search operations.

Functions

- static `rx_err_t` `internal_find_timeout_config` (`const uint32_t` timeout_ms, `const iwdt_timeout_entry_t` **entry)
Find best timeout configuration for requested timeout.
- static `rx_err_t` `internal_configure_iwdt_control_register` (`const iwdt_timeout_entry_t` *config)
Configure IWDT control register (IWDT`r) from timeout table entry.
- static `rx_err_t` `internal_configure_iwdt_registers` (`void`)
Configure IWDT reset and sleep-count behavior registers.
- `rx_err_t` `rx_hal_iwdt_init` (`const uint32_t` timeout_ms)
Initialize the Independent Watchdog Timer.
- `void` `rx_hal_iwdt_feed` (`void`)
Feed the watchdog timer to prevent reset.
- `bool` `rx_hal_iwdt_was_reset` (`void`)
Check if system was reset by watchdog.
- `rx_iwdt_reset_cause_t` `rx_hal_iwdt_get_reset_cause` (`void`)
Get detailed watchdog reset cause.
- `void` `rx_hal_iwdt_clear_status` (`void`)
Clear watchdog status flags.
- static `int32_t` `internal_find_task` (`const char` *task_name)
Find task index by name in the registered tasks array.
- `rx_err_t` `rx_hal_iwdt_register_task` (`const char` *task_name, `uint32_t` timeout_ms)
Register a task for watchdog monitoring.
- `void` `rx_hal_iwdt_task_heartbeat` (`const char` *task_name)
Record a task heartbeat to indicate liveness.
- `rx_err_t` `rx_hal_iwdt_check_tasks` (`void`)
Check all monitored tasks for timeout violations.
- `const char` * `rx_hal_iwdt_get_failed_task` (`void`)
Get name of last failed task for post-mortem analysis.

Variables

- static const `iwdt_timeout_entry_t s_timeout_table []`
IWDT timeout configuration lookup table.
- static const `uint32_t s_iwdt_timeout_table_size`
Number of entries in the timeout lookup table.
- static const char *const `s_tag = "IWDT"`
Log tag for IWDT module.
- static `iwdt_init_state_t s_iwdt_initialized = k_iwdt_not_initialized`
Flag indicating IWDT has been initialized.
- static `task_monitor_state_t s_task_monitor = {}`
Module state for task monitoring (static allocation).

8.123.1 Detailed Description

Independent Watchdog Timer (IWDT) Driver Implementation for RX72N.

Implements hardware and software watchdog functionality for safety-critical system monitoring. The IWDT provides protection against software hangs, deadlocks, and infinite loops through automatic system reset.

Implementation Architecture

Register Layout (IWDT\`r - 0x00088030)

```

* Bits [15:14] RPSS - Window Start Position
* +-----+ +-----+ +-----+ +-----+ +-----+ +-----+ +-----+ +-----+
* | - |RPSS1|RPSS0| - |RP- |RP- | - | - |CKS3|CKS2|CKS1|CKS0| - | - |TOPS1|TOPS0|
* | b15 | b14 | b13 | b12 |ES1 |ES0 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
* +-----+ +-----+ +-----+ +-----+ +-----+ +-----+ +-----+ +-----+
* TOPS[1:0]: Timeout Period Select (00=1024, 01=4096, 10=8192, 11=16384 cycles)
* CKS[3:0]: Clock Division Ratio (0000=/1, 0010=/16, 0100=/32, 1111=/128)
* RPES[1:0]: Window End Position (00=75%, 01=50%, 10=25%, 11=0%)
* RPSS[1:0]: Window Start Position (00=100%, 01=75%, 10=50%, 11=25%)
*

```

IWDT Refresh Sequence (IWDTRR)

```

* Refresh Sequence (must not be interrupted):
* +-----+
* | Step 1: Write 0x00 to IWDTRR          |
* | Step 2: Write 0xFF to IWDTRR          |
* |           v                           |
* | Counter reloads to initial value      |
* +-----+
* WARNING: Incomplete sequence = Refresh Error -> System Reset
*

```

Timeout Calculation

```

* Timeout = (TOPS_cycles x CKS_divisor) / IWDTCCLK
*
* Where:
* - TOPS_cycles = 1024, 4096, 8192, or 16384 (based on TOPS bits)
* - CKS_divisor = 1, 16, 32, 64, or 128 (based on CKS bits)
* - IWDTCCLK = 120 kHz (dedicated oscillator)
*
* Example: TOPS=16384, CKS=16
* Timeout = (16384 x 16) / 120000 = 2.18 seconds
*

```

Performance Characteristics

Function	Execution Time	Stack Usage	Notes
rx_hal_iwdt_init()	~50 us	24 bytes	One-time setup
rx_hal_iwdt_feed()	~2 us	8 bytes	Critical path
rx_hal_iwdt_was_reset()	~5 us	8 bytes	Register read
rx_hal_iwdt_check_tasks()	~10 us x N	32 bytes	N = task count
rx_hal_iwdt_register_task()	~15 us	16 bytes	String copy
internal_find_timeout_config()	~3 us	8 bytes	Table lookup

Memory Usage

Category	Size	Notes
Code (.text)	~1.5 KB	All functions
Constants (.rodata)	~48 bytes	Timeout table (6 entries)
Static data (.bss)	~520 bytes	Task monitor state
Stack (max)	32 bytes	deepest call chain

Thread Safety

- [rx_hal_iwdt_feed\(\)](#): Safe from ISRs (uses atomic disable/enable)
- Task functions: Not thread-safe (caller must synchronize)
- Init/config: Call only from single thread during startup

Hardware Configuration

- Window mode: Disabled (refresh allowed anytime)
- Reset action: Full chip reset (not NMI)
- Sleep behavior: Continues counting during WAIT/STOP
- Clock source: Dedicated 120 kHz oscillator (independent of PCLK)

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, or recursion
- Rule 2: [OK] All loops bounded by s_iwdt_timeout_table_size or k_iwdt_max_tasks
- Rule 3: [OK] Zero dynamic memory allocation (all static)
- Rule 4: [OK] All functions < 60 lines
- Rule 5: [OK] Minimum 2 validation checks per function
- Rule 6: [OK] File-scope statics (s_), local variables at narrowest scope
- Rule 7: [OK] All return values checked or explicitly cast to (void)
- Rule 8: [OK] C23 typed enums for all constants
- Rule 9: [OK] Single-level pointers, function pointers for DIP
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

SOLID Principles

- S: Module has single responsibility (watchdog management)
- O: Configurable via timeout table without code modification
- L: Consistent rx_err_t returns across all functions
- I: Separate APIs for hardware vs task monitoring
- D: Hardware access via [iwdt\(\)](#) accessor, mockable for testing

8.123.2 Data Structure Documentation

8.123.2.1 struct iwdt`timeout`entry`t

Timeout configuration lookup table entry.

Maps a human-readable timeout value (milliseconds) to the hardware register values (TOPS and CKS) needed to achieve approximately that timeout period.

Memory Layout (8 bytes)

```
* Offset 0: timeout_ms [4 bytes, uint32_t]
* Offset 4: tops      [2 bytes, uint16_t]
* Offset 6: cks       [2 bytes, uint16_t]
* Total: 8 bytes (no padding needed)
*
```

Timeout Calculation Formula

```
* Actual_Timeout = (TOPS_cycles x CKS_divisor) / IWDTCCLK
*
* Where IWDTCCLK = 120,000 Hz
*
```

Invariant

```
timeout_ms >= k_iwdt_timeout_min_ms
timeout_ms <= k_iwdt_timeout_max_ms
tops is valid TOPS register value
cks is valid CKS register value
```

Example:

```
// Look up a configuration entry and read its fields
const iwdt_timeout_entry_t* cfg = nullptr;
rx_err_t err = internal_find_timeout_config(1000, &cfg);
if (err == k_rx_ok) {
    // cfg->tops and cfg->cks are ready to combine into IWDTCCLK
    // cfg->timeout_ms reports the actual (>= requested) timeout
}
```

Collaboration diagram for iwdt_timeout_entry_t:

Data Fields

uint16_t	cks	CKS bits [7:4] - Clock Division Select (/1, /16, /32, /64, /128)
uint32_t	timeout_ms	Target timeout in milliseconds (approximate)
uint16_t	tops	TOPS bits [1:0] - Timeout Period Select (1024-16384 cycles)

8.123.3 Enumeration Type Documentation

8.123.3.1 iwdt`buffer`size`constants`

```
enum iwdt\_buffer\_size\_constants\_t : uint8_t
```

Task monitoring string buffer size constants.

Defines buffer sizes for task names and log messages. Sized for embedded system constraints while allowing descriptive task names.

Size Rationale

- * `k_task_name_max_len` (16):
- * - Fits typical task names: "MotorCtrl", "SpiComm", "MainLoop"
- * - Keeps `task_monitor_t` struct compact (~32 bytes per task)
- * - Allows up to 8 tasks x 32 bytes = 256 bytes array
- *
- * `k_log_msg_buffer_size` (64):
- * - Fits formatted message: "Task deadlock: %s (timeout 16384 ms)"
- * - Stack-allocated (not static) to allow reentrant logging
- *

Invariant

```
k_task_name_cmp_len == k_task_name_max_len - 1
k_log_msg_buffer_size >= 48 (minimum for deadlock message)
```

Since

Version 1.0.0

Enumerator

k_task_name_max_len	Maximum task name length including null terminator
k_task_name_cmp_len	Length for strcmp comparison (excludes null)
k_log_msg_buffer_size	Log message buffer size for snprintf formatting

Definition at line 249 of file [rx_iwdt.c](#).

```
00249      : uint8_t {
00250  k_task_name_max_len  = 16, /**< Maximum task name length including null terminator */
00251  k_task_name_cmp_len  = 15, /**< Length for strcmp comparison (excludes null) */
00252  k_log_msg_buffer_size = 64, /**< Log message buffer size for snprintf formatting */
00253 } iwdt_buffer_size_constants_t;
```

8.123.3.2 iwdt`init`state`

```
enum iwdt\_init\_state\_t : uint8_t
```

IWDT initialization state tracking.

Tracks whether the IWDT has been initialized. Used to prevent:

- Double initialization (hardware watchdog cannot be reconfigured)
- API calls before initialization
- Feed operations on uninitialized watchdog

State Transitions

```
* [Power On] -> k_iwdt_not_initialized
* |
* | rx_hal_iwdt_init() succeeds
* v
* k_iwdt_initialized
* |
* | (No return path - IWDT cannot be stopped)
* v
* [System Reset] -> k_iwdt_not_initialized
*
```

Warning

Once initialized, IWDT cannot be disabled (hardware feature)

Since

Version 1.0.0

Enumerator

k_iwdt_not_initialized	IWDT not initialized - API calls will fail
k_iwdt_initialized	IWDT initialized - feed required periodically

Definition at line 219 of file [rx_iwdt.c](#).

```
00219      : uint8_t {
00220  k_iwdt_not_initialized = 0, /**< IWDT not initialized - API calls will fail */
00221  k_iwdt_initialized    = 1, /**< IWDT initialized - feed required periodically */
00222 } iwdt_init_state_t;
```

8.123.3.3 iwdt timeout limits

```
enum iwdt_timeout_limits_t : uint32_t
```

IWDT timeout validation limits.

Defines the valid range of timeout values for the IWDT. These limits are derived from hardware capabilities and practical system requirements.

Limit Rationale

```
* Minimum (1 ms):
* - Hardware can achieve ~8.5 ms minimum (1024/120kHz)
* - Using 1 ms as software minimum allows validation before hardware config
* - Actual hardware minimum will be selected from timeout table
*
* Maximum (16384 ms):
* - Hardware maximum = 16384 x 128 / 120000 ~ 17.5 seconds
* - Conservative limit (16.4 s) ensures reasonable failure detection
* - Longer timeouts make watchdog less effective
*
```

Invariant

```
k_iwdt_timeout_min_ms < k_iwdt_timeout_max_ms
```

Values are compile-time constants

Since

Version 1.0.0

Enumerator

k_iwdt_timeout_min_ms	Minimum valid timeout in milliseconds. Software validation limit (1 ms). Actual hardware minimum is ~128 ms with TOPS=16384, CKS=1. Used for early parameter validation.
k_iwdt_timeout_max_ms	Maximum valid timeout in milliseconds. Hardware maximum is ~17.5 seconds with TOPS=16384, CKS=128. Using 16384 ms as conservative limit for practical watchdog operation.

Definition at line 176 of file [rx_iwdt.c](#).

```

00176         : uint32_t {
00177     /**
00178     * @brief Minimum valid timeout in milliseconds
00179     * @details Software validation limit (1 ms). Actual hardware minimum
00180     * is ~128 ms with TOPS=16384, CKS=1. Used for early parameter validation.
00181     */
00182     k_iwdt_timeout_min_ms = 1,
00183
00184     /**
00185     * @brief Maximum valid timeout in milliseconds
00186     * @details Hardware maximum is ~17.5 seconds with TOPS=16384, CKS=128.
00187     * Using 16384 ms as conservative limit for practical watchdog operation.
00188     */
00189     k_iwdt_timeout_max_ms = 16384,
00190 } iwdt_timeout_limits_t;

```

8.123.4 Function Documentation

8.123.4.1 `internal_configure_iwdt_control_register()`

```

rx_err_t internal_configure_iwdt_control_register (
    const iwdt\_timeout\_entry\_t * config)    [static]

```

Configure IWDT control register (IWDT\`r) from timeout table entry.

Builds and writes the IWDT\`r register value from a timeout configuration entry. Combines TOPS, CKS, RPES, and RPSS fields into a single 16-bit value.

Register Construction

```

*   IWDT\`r = TOPS | CKS | RPES | RPSS
*
*   Where:
*   - TOPS[1:0]: Timeout Period Select (from config)
*   - CKS[7:4]: Clock Division Ratio (from config)
*   - RPES[9:8]: Window End = 0% (disabled)
*   - RPSS[13:12]: Window Start = 100% (full window)
*

```

Register Write Sequence

```

*   1. Validate config pointer (NULL check)
*   2. Validate hardware pointer (iwdt() check)
*   3. Build IWDT\`r value from fields
*   4. Write to IWDT\`r register
*

```

Precondition

config must point to valid [iwdt_timeout_entry_t](#)
 IWDT not yet started (first refresh not performed)
[iwdt\(\)](#) returns valid hardware register pointer

Postcondition

IWDT\`r configured with specified timeout and window settings

Note

Not thread-safe: must be called from single-threaded initialization context
 Window mode disabled (RPES=0%, RPSS=100%)
 Register can only be configured before first refresh

Warning

IWDT\`r becomes read-only after first refresh sequence

Here is the caller graph for this function:

8.123.4.2 internal`configure`iwdt`registers()

```
rx_err_t internal_configure_iwdt_registers (
    void ) [static]
```

Configure IWDTR reset and sleep-count behavior registers.

Configures IWDTR\`r (Reset Control) and IWDTCSTPR (Count Stop Control) registers for safety-critical operation:

- Full chip reset on timeout (not NMI)
- Continue counting during sleep modes

Register Configuration

```
* IWDTR\`r (Reset Control Register):
* +-----+
* | Bit 7 (RSTIRQS) = 1: Reset on underflow/error      |
* |              0: NMI on underflow/error (not used) |
* +-----+
* Using reset (1) for safety - NMI could be masked/ignored
*
* IWDTCSTPR (Count Stop Control Register):
* +-----+
* | Bit 7 (SLCSTP) = 0: Continue counting in sleep mode |
* |              1: Stop counting in sleep (not used) |
* +-----+
* Continue counting for safety - sleeping should not bypass watchdog
*
```

Precondition

IWDTR not yet initialized (s_iwdt_initialized == k_iwdt_not_initialized)
[iwdt\(\)](#) returns valid hardware register pointer
 Called after [internal_configure_iwdt_control_register\(\)](#)

Postcondition

IWDTR\`r configured for reset action
 IWDTCSTPR configured to continue counting in sleep

Note

Not thread-safe: must be called from single-threaded initialization context
 These registers can only be written before first refresh

Warning

Changing RSTIRQS to NMI may compromise system safety

Since

Version 1.0.0

Here is the call graph for this function:

Here is the caller graph for this function:

8.123.4.3 internal_find_timeout_config()

```
rx_err_t internal_find_timeout_config (
    const uint32_t timeout_ms,
    const iwdt_timeout_entry_t ** entry) [static]
```

Find best timeout configuration for requested timeout.

Performs linear search through `s_timeout_table` to find the first entry whose `timeout_ms` is $\geq$ the requested value. This provides the smallest timeout that meets or exceeds the requirement.

Algorithm

- * 1. Validate table is not empty
- * 2. Validate output pointer is not nullptr
- * 3. Linear scan through sorted table:
 - * - If `entry.timeout_ms` $\geq$ requested: return entry pointer
- * 4. If no entry found: requested timeout exceeds maximum
- *

Complexity

- Time: $O(n)$ where $n = s_iwdt_timeout_table_size$ (typically 6)
- Space: $O(1)$ - no additional memory allocated

Precondition

timeout_ms $\geq$ k_iwdt_timeout_min_ms
 entry $\neq$ nullptr
 s_timeout_table populated (compile-time guarantee)

Postcondition

*entry points to valid table entry with timeout_ms $\geq$ requested
 *entry is const - returned entry must not be modified

Note

Returns pointer to static data - valid for program lifetime
 Selected timeout may be longer than requested (next available)

Example:

```
const iwdt_timeout_entry_t* config = nullptr;
rx_err_t err = internal_find_timeout_config(1000, &config);
if (err == k_rx_ok) {
    // config->tops and config->cks ready for IWDT\
    // config->timeout_ms = actual timeout ( $\geq$  1000)
}
```

Definition at line 473 of file [rx_iwdt.c](#).

```
00475 {
00476     if (s_iwdt_timeout_table_size == 0U) {
00477         return k_rx_err_invalid_arg;
00478     }
00479
00480     if (entry == nullptr) {
00481         return k_rx_err_invalid_arg;
00482     }
00483
00484     /* Find first entry with timeout  $\geq$  requested */
00485     for (uint32_t i = 0; i < s_iwdt_timeout_table_size; i++) {
00486         if (s_timeout_table[i].timeout_ms  $\geq$  timeout_ms) {
00487             *entry = &s_timeout_table[i];
00488             return k_rx_ok;
00489         }
00490     }
00491
00492     /* No suitable configuration found */
00493     return k_rx_err_invalid_arg;
00494 }
```

Here is the caller graph for this function:

8.123.4.4 rx_hal_iwdt_clear_status()

```
void rx_hal_iwdt_clear_status (
    void )
```

Clear watchdog status flags.

Clears the UNDFE (underflow) and REFEE (refresh error) flags in the IWDT Status Register. These flags are "write-0-to-clear" type - writing 0 to a flag clears it, writing 1 has no effect.

Clear Sequence

- * 1. Read IWDTSR (get current status)
- * 2. AND with ~(UNDFE | REFEE) to clear both flags
- * 3. Write back to IWDTSR
- *
- * Note: Read-modify-write is safe because flags are write-0-to-clear
- *

Precondition

Status has been read via [rx_hal_iwdt_was_reset\(\)](#) or [rx_hal_iwdt_get_reset_cause\(\)](#)

Postcondition

UNDFE flag cleared
REFEE flag cleared

Note

On host builds, function is a no-op
Call after reading status at startup to prepare for next reset

Example:

```
// Startup diagnostic sequence
if (rx_hal_iwdt_was_reset()) {
    rx_iwdt_reset_cause_t cause = rx_hal_iwdt_get_reset_cause();
    log_watchdog_reset(cause);
}
// Clear flags so next reset can be detected
rx_hal_iwdt_clear_status();
```

See also

[rx_hal_iwdt_get_reset_cause\(\)](#) Get specific cause

Since

Version 1.0.0

Definition at line 1037 of file rx_iwdt.c.

```

01038 {
01039 #ifdef __RX__
01040 /*
01041  * Clear status flags by writing 0 to the flag bits
01042  *
01043  * Bits 14-15 are write-0-to-clear
01044  */
01045 iwdt()->iwdtsr &= (uint16_t) ~(uint16_t)(k_iwdt_sr_undff | k_iwdt_sr_refef);
01046
01047 #else
01048 /* Host-side stub - no operation */
01049 #endif
01050 }
```

References [iwdt\(\)](#), [rx_iwdt_regs_t::iwdtsr](#), [k_iwdt_sr_refef](#), and [k_iwdt_sr_undff](#).

Here is the call graph for this function:

8.123.4.5 rx`hal`iwdt`feed()

```

void rx_hal_iwdt_feed (
    void )
```

Feed the watchdog timer to prevent reset.

Feed (refresh) the watchdog timer.

Performs the IWDT refresh sequence by writing the magic values 0x00 then 0xFF to the IWDTRR register. This resets the down-counter to its initial value, preventing timeout and system reset.

Refresh Sequence (Atomic Operation)

```

* +-----+
* | 1. Disable interrupts (save PSW)          |
* | 2. Write 0x00 to IWDTRR                   |
* | 3. Write 0xFF to IWDTRR                   |
* | 4. Restore interrupt state                 |
* +-----+
* \\rITICAL: Steps 2 and 3 must not be interrupted!
*
```

Timing Requirements

- * - Execution time: ~2 us including interrupt disable/enable
- * - Must be called faster than configured timeout period
- * - Typical call rate: Every 100-500 ms depending on timeout
- *

Precondition

IWDT must be initialized via [rx_hal_iwdt_init\(\)](#)
 Called at rate faster than configured timeout

Postcondition

IWDT counter reset to initial value
 Interrupt state restored to previous value

Note

Safe to call from ISRs (uses atomic disable/restore)
 On host builds, function is a no-op

Warning

Incomplete refresh sequence causes refresh error -> system reset
 Missing calls to this function cause timeout -> system reset

Example:

```
// Main supervision loop
while (1) {
    // Check all tasks for deadlock
    rx_err_t err = rx_hal_iwdt_check_tasks();

8.123.4.6 rx_hal_iwdt_get_reset_cause()

```

rx_iwdt_reset_cause_t rx_hal_iwdt_get_reset_cause (
    void )

```

Get detailed watchdog reset cause.

Get detailed reset cause from IWDT.

Reads the IWDT Status Register to determine the specific cause of the last watchdog reset. Refresh errors take priority over underflow since they indicate a software bug in the refresh sequence.

Reset Cause Priority

- * 1. Refresh Error (REFEF=1): Invalid refresh sequence
 - * - Incomplete 0x00/0xFF write
 - * - Write occurred outside window (if window mode enabled)
- * 2. Underflow (UNDF=1): Counter reached zero
 - * - rx_hal_iwdt_feed() not called within timeout period
 - * - Software hang, deadlock, or infinite loop
- * 3. None: No watchdog reset occurred
 - * - Power-on reset, external reset, or other cause

Precondition

Can be called before [rx_hal_iwdt_init\(\)](#)

Status flags preserved across reset

Postcondition

Status flags NOT cleared (call [rx_hal_iwdt_clear_status\(\)](#) to clear)

Note

On host builds, always returns `k_iwdt_reset_none`

Refresh error has priority over underflow in return value

Example:

```
rx_iwdt_reset_cause_t cause = rx_hal_iwdt_get_reset_cause();
switch (cause) {
    case k_iwdt_reset_refresh_error:
        uart_debug_puts("ERROR: Watchdog refresh sequence error!\r\n");
        break;
    case k_iwdt_reset_underflow:
        uart_debug_puts("WARN: Watchdog timeout - software hang detected\r\n");
        break;
    case k_iwdt_reset_none:
    default:
        uart_debug_puts("Normal startup\r\n");
        break;
}
rx_hal_iwdt_clear_status(); // Clear flags after reading
```

Here is the call graph for this function:

8.123.4.7 rx`hal`iwdt`init()

```
rx_err_t rx_hal_iwdt_init (
    const uint32_t timeout_ms) [nodiscard]
```

Initialize the Independent Watchdog Timer.

Configures and starts the hardware IWDT with the specified timeout period. Once started, the watchdog cannot be stopped - periodic calls to [rx_hal_iwdt_feed\(\)](#) are required to prevent system reset.

Initialization Sequence

- * 1. Validate not already initialized
- * 2. Validate timeout_ms within range
- * 3. Look up timeout configuration in table
- * 4. Configure IWDTR\`r (timeout period, clock divisor, window)
- * 5. Configure IWDTR\`r (reset action - not NMI)
- * 6. Configure IWDTCSTPR (continue counting in sleep)
- * 7. Perform first refresh (starts the watchdog)
- * 8. Set initialized flag
- *

Point of No Return

- * After step 7 (first refresh), the IWDT is running and CANNOT be stopped.
- * Any failure after this point leaves system in watchdog-protected state.
- *

Precondition

IWDT must not be already initialized

timeout_ms in range [k_iwdt_timeout_min_ms, k_iwdt_timeout_max_ms]

System startup, single-threaded context

Postcondition

IWDT running with selected timeout period

s_iwdt_initialized set to k_iwdt_initialized

Periodic [rx_hal_iwdt_feed\(\)](#) calls now required

Note

On host builds (non-RX), skips hardware access but sets initialized flag

Actual timeout >= requested (selected from lookup table)

Warning

Once initialized, IWDT cannot be disabled (requires hard reset)

Must call [rx_hal_iwdt_feed\(\)](#) faster than timeout period

Example:

```
// Initialize with 2 second timeout
rx_err_t err = rx_hal_iwdt_init(2000);
if (err != k_rx_ok) {
    // Handle error - system cannot start safely
    while (1) { // halt }
}

// Now must feed periodically
while (1) {
    // ... main loop ...
    rx_hal_iwdt_feed(); // Must occur every < 2 seconds
    tx_thread_sleep(100);
}
```

Here is the call graph for this function:

8.123.4.8 rx_hal_iwdt_was_reset()

```

bool rx_hal_iwdt_was_reset (
    void ) [nodiscard]

```

Check if system was reset by watchdog.

Check if last reset was caused by watchdog timeout.

Reads the IWDT Status Register (IWDTSR) to determine if the previous system reset was caused by watchdog timeout (underflow) or refresh error. This function should be called early in startup for diagnostics.

Status Register Flags

```
* IWDTSR Bit 14 (UNDFE) - Underflow Flag:
* - 1: Counter reached 0 (timeout occurred)
* - 0: No underflow
*
* IWDTSR Bit 15 (REFEF) - Refresh Error Flag:
* - 1: Invalid refresh sequence detected
* - 0: No refresh error
*
```

Precondition

Can be called before [rx_hal_iwdt_init\(\)](#)
 Status flags preserved across reset (hardware feature)

Postcondition

Status flags NOT cleared (call [rx_hal_iwdt_clear_status\(\)](#) to clear)

Note

On host builds, always returns false
 Call [rx_hal_iwdt_get_reset_cause\(\)](#) for specific cause

Example:

```
// Check at startup
if (rx_hal_iwdt_was_reset()) {
    uart_debug_puts("[WARN] Recovered from watchdog reset!\r\n");
    const char* failed = rx_hal_iwdt_get_failed_task();
    if (failed != nullptr) {
        uart_debug_printf("Failed task: %s\r\n", failed);
    }
}
```

Here is the call graph for this function:

8.123.5 Variable Documentation

8.123.5.1 s`iwdt`initialized

```
iwdt\_init\_state\_t s_iwdt_initialized = k\_iwdt\_not\_initialized [static]
```

Flag indicating IWDT has been initialized.

Tracks initialization state to prevent:

- Multiple calls to [rx_hal_iwdt_init\(\)](#) (hardware cannot be reconfigured)
- API calls before init (undefined behavior prevention)
- Feed operations on uninitialized watchdog

Thread Safety

- Set only once during initialization (single-threaded startup)
- Read by all API functions (safe - single write, multiple reads)
- Never reset (IWDT cannot be stopped once started)

Invariant

Value is either [k_iwdt_not_initialized](#) or [k_iwdt_initialized](#)

Once set to [k_iwdt_initialized](#), never changes until reset

Warning

Do not modify directly - use [rx_hal_iwdt_init\(\)](#) only

Since

Version 1.0.0

Definition at line [418](#) of file [rx_iwdt.c](#).

Referenced by [internal_configure_iwdt_registers\(\)](#), [rx_hal_iwdt_check_tasks\(\)](#), [rx_hal_iwdt_get_failed_task\(\)](#), and [rx_hal_iwdt_init\(\)](#).

8.123.5.2 `s_iwdt_timeout_table_size`

```
const uint32_t s_iwdt_timeout_table_size [static]
```

Initial value:

```
sizeof(s_timeout_table) / sizeof(s_timeout_table[0])
```

Number of entries in the timeout lookup table.

Compile-time constant for table bounds checking. Used in [internal_find_timeout_config\(\)](#) for loop bounds (NASA Power of 10 Rule 2).

Invariant

```
s_iwdt_timeout_table_size == 6 (current implementation)
s_iwdt_timeout_table_size > 0
```

Since

Version 1.0.0

Definition at line 367 of file [rx_iwdt.c](#).

Referenced by [internal_find_timeout_config\(\)](#).

8.123.5.3 `s_tag`

```
const char* const s_tag = "IWDT" [static]
```

Log tag for IWDT module.

Identifies log messages from this module in system logs. Uses the tag "IWDT" (uppercase) to match S\rEAMING_SNAKE_CASE convention for log tags.

Log Message Format

```
* [IWDT] INFO: Registered task for monitoring
* [IWDT] ERROR: Task deadlock: MotorCtrl (timeout 500 ms)
*
```

Note

Pointer to string literal (stored in .rodata section)

Warning

Do not modify (const pointer to const data)

Since

Version 1.0.0

Definition at line 394 of file [rx_iwdt.c](#).

8.123.5.4 s`timeout`table

```
const iwdt_timeout_entry_t s_timeout_table[] [static]
```

Initial value:

```
= {
    { .timeout_ms = 128, .tops = k_iwdt_tops_16384, .cks = k_iwdt_cks_div_1 },
    { .timeout_ms = 512, .tops = k_iwdt_tops_4096, .cks = k_iwdt_cks_div_16 },
    { .timeout_ms = 1000, .tops = k_iwdt_tops_8192, .cks = k_iwdt_cks_div_16 },
    { .timeout_ms = 2048, .tops = k_iwdt_tops_16384, .cks = k_iwdt_cks_div_16 },
    { .timeout_ms = 8192, .tops = k_iwdt_tops_16384, .cks = k_iwdt_cks_div_64 },
    { .timeout_ms = 16384, .tops = k_iwdt_tops_16384, .cks = k_iwdt_cks_div_128 },
}
```

IWDT timeout configuration lookup table.

Static lookup table mapping requested timeout values to optimal IWDT register configurations. Entries are sorted by increasing timeout for linear search efficiency. The first entry with timeout_ms >= requested value is selected.

Table Organization

* Index	Request	TOPS	CKS	Actual Timeout	Use Case
* 0	128ms	16384	/1	~136ms	Fast control loops
* 1	512ms	4096	/16	~546ms	Normal operations
* 2	1000ms	8192	/16	~1.09s	Default timeout
* 3	2048ms	16384	/16	~2.18s	Moderate operations
* 4	8192ms	16384	/64	~8.74s	Slow processes
* 5	16384ms	16384	/128	~17.48s	Long operations
*					

Calculation Examples

```
* Entry 0: (16384 x 1) / 120000 = 0.1365s = 136.5ms
* Entry 2: (8192 x 16) / 120000 = 1.092s = 1092ms
* Entry 5: (16384 x 128) / 120000 = 17.48s = 17476ms
*
```

Note

Values are slightly longer than requested to provide safety margin

Table is const and placed in .rodata section (48 bytes total)

Warning

Do not modify table at runtime (const data)

Include dependency graph for rx_lpc.c:

Enumerations

- enum `rx_lpc_init_state_t` : `uint8_t` { `k_lpc_not_initialized` = 0 , `k_lpc_initialized` = 1 }
Driver initialization tracking.
- enum `rx_lpc_sbycr_bits_t` : `uint16_t` { `k_sbycr_sby` = 0x8000U }
SBYCR bit definitions (RX72N Manual Section 11.2.1, page 405).
- enum `rx_lpc_poll_limits_t` : `uint16_t` { `k_opcmstf_poll_max` = 1024U }
Bounded-retry limits for register polls.

Functions

- static rx_err_t [internal_translate_opcc_mode](#) (rx_lpc_opcc_mode_t mode, uint8_t *opcm_↔ bits)
Translate OPCCR mode enum to OPCM[2:0] field value.
- static uint8_t [internal_assemble_dpsbycr](#) (rx_lpc_deep_power_t deep_power, bool keep_io)
Program DPSIER0..DPSIER3 from the 32-bit wake mask.
- rx_err_t [rx_lpc_init](#) (void)
Initialize the Low Power Consumption driver.
- rx_err_t [rx_lpc_set_operating_power](#) (rx_lpc_opcc_mode_t mode)
Switch the MCU to a different operating-power-control mode (implementation).
- rx_err_t [rx_lpc_enter_sleep](#) (void)
Enter Sleep low-power mode (implementation).
- rx_err_t [rx_lpc_enter_software_standby](#) (void)
Enter Software Standby mode (implementation).
- rx_err_t [rx_lpc_enter_deep_software_standby](#) (uint32_t wake_mask, rx_lpc_deep_power_t deep_power, bool keep_io)
Enter Deep Software Standby mode.
- bool [rx_lpc_was_deep_standby_wake](#) (void)
Report whether the most recent reset was a Deep Standby wake.
- rx_err_t [rx_lpc_get_wake_flags](#) (uint32_t *flags)
Read the latched Deep Software Standby wake-source bitfield (implementation).

Variables

- static rx_lpc_init_state_t [s_initialized](#) = [k_lpc_not_initialized](#)
Driver initialization flag.
- static rx_lpc_last_mode_t [s_last_mode](#) = [k_lpc_mode_none](#)
Last low-power mode the driver attempted to enter.
- static bool [s_was_deep_standby_wake](#) = false
Latched "last reset was deep-standby wake" flag (set by rx_lpc_init).
- static uint32_t [s_latched_wake_flags](#) = 0U
Latched wake flags read from DPSIFR0..DPSIFR3 at init time.

8.125.1 Detailed Description

Low Power Consumption (LPC) HAL Driver Implementation for RX72N.

Implements the Sleep, Software Standby, and Deep Software Standby mode entry paths plus the OPCCR (Operating Power Control) selector described in the RX72N Hardware Manual Chapter 11.

Register Write Protocol

All writes to SBYCR, OPCCR, RSTCKCR, and DPSBYCR require PRC1 to be unlocked via PRCR (key 0xA5, PRC1=1). The driver unlocks, writes, and re-locks PRCR around every such access. PRCR writes are guarded by `#ifdef __RX__` so host-side unit tests can exercise the driver without hardware-mapped register access.

Low-Power Entry Instruction

All three low-power modes are entered by executing the WAIT instruction on RX. SBYCR.SSBY and DPSBYCR.DPSBY are set beforehand to select which flavour of low power the WAIT enters:

```
* SSBY=0, DPSBY=0 -> Sleep (WAIT)
* SSBY=1, DPSBY=0 -> Software Standby (WAIT)
* SSBY=1, DPSBY=1 -> Deep Software Standby (WAIT)
*
```

NASA Power of 10 Compliance

- Rule 1: [OK] No goto/setjmp/recursion
- Rule 2: [OK] OPCMTSF poll bounded by k_opcmtsf_poll_max retries
- Rule 3: [OK] Zero dynamic allocation (file-scope statics only)
- Rule 4: [OK] All functions < 60 lines
- Rule 5: [OK] >= 2 pre/post conditions per function
- Rule 6: [OK] s_*-prefixed file-scope statics, locals at narrowest scope
- Rule 7: [OK] All return values checked or explicitly cast to (void)
- Rule 8: [OK] C23 typed enums, preprocessor only for RX/UNIT_TEST guards
- Rule 9: [OK] Single-level pointers
- Rule 10: [OK] Compiles with -Wall -Wextra -Werror

8.125.2.1 rx_lpc_init_state_t

enum [rx_lpc_init_state_t](#) : uint8_t

Driver initialization tracking.

Since

Version 1.0.0

Enumerator

k_lpc_not_initialized	rx_lpc_init() has not been called
k_lpc_initialized	rx_lpc_init() completed successfully

Definition at line 73 of file [rx_lpc.c](#).

```
00073      : uint8_t {
00074  k_lpc_not_initialized = 0, /**< rx_lpc_init() has not been called */
00075  k_lpc_initialized    = 1, /**< rx_lpc_init() completed successfully */
00076 } rx_lpc_init_state_t;
```

8.125.2.2 rx_lpc_poll_limits_t

enum [rx_lpc_poll_limits_t](#) : uint16_t

Bounded-retry limits for register polls.

OPCCR.OPCMTSF typically clears within a few hundred cycles. 1024 is a generous ceiling that still keeps the poll bounded per NASA Rule 2.

Since

Version 1.0.0

Enumerator

k_opcmtsf_poll_max	Max OPCMTSF poll iterations
--------------------	-----------------------------

Definition at line 102 of file [rx_lpc.c](#).

```
00102      : uint16_t {
00103  k_opcmtsf_poll_max = 1024U, /**< Max OPCMTSF poll iterations */
00104 } rx_lpc_poll_limits_t;
```

8.125.2.3 rx`lpc`sbycr`bits`

```
enum rx_lpc_sbycr_bits_t : uint16_t
```

SBYCR bit definitions (RX72N Manual Section 11.2.1, page 405).

Only the two bits manipulated by this driver are declared here. Other bits in SBYCR (OPE) are left at their reset values.

Since

Version 1.0.0

Enumerator

k_sbycr_ssbby	Bit 15: Software Standby Select (0=sleep, 1=standby)
---------------	--

Definition at line 88 of file rx_lpc.c.

```
00088      : uint16_t {
00089      k_sbycr_ssbby = 0x8000U, /**< Bit 15: Software Standby Select (0=sleep, 1=standby) */
00090 } rx_lpc_sbycr_bits_t;
```

8.125.3 Function Documentation

8.125.3.1 internal`assemble`dpsbycr()

```
uint8_t internal_assemble_dpsbycr (
    rx_lpc_deep_power_t deep_power,
    bool keep_io) [static]
```

Program DPSIER0..DPSIER3 from the 32-bit wake mask.

Each byte of the mask maps directly to one DPSIER register as described in rx_lpc.h. The NMI bit (DPSIER2.DNMIE) is documented as write-once by the hardware; this driver re-asserts it on every call and the hardware will ignore the redundant writes after the first.

Precondition

dps_regs() returns a valid (hardware or host-mocked) pointer

Postcondition

DPSIER0..DPSIER3 reflect the enabled wake sources

Since

Version 1.0.0

Assemble DPSBYCR value for a deep-standby entry

Internal helper. The only caller (rx_lpc_enter_deep_software_standby) validates deep_power against the three defined rx_lpc_deep_power_t enumerators before calling, so the switch does not need a default branch (NASA Rule 5: validate at boundaries, not inside private helpers). The DPSBY bit is always set because this value is only used on the deep-standby entry path.

Precondition

deep_power is one of k_lpc_deep_ram_usb_on / k_lpc_deep_ram_usb_off / k_lpc_deep_lvd_off (enforced by caller)

Postcondition

Return value contains at most the bits DEEPCUT[1:0], IOKEEP, DPSBY

Since

Version 1.0.0

Definition at line 215 of file rx_lpc.c.

```

00216 {
00217 /* LUT keyed by rx_lpc_deep_power_t enumerator value (0..2). Using a LUT
00218  * rather than a switch eliminates the synthetic "unreachable default"
00219  * branch that gcov tracks: once deep_power is pre-validated by the
00220  * caller, a switch still produces a default fall-through branch that
00221  * no public API path can execute. The LUT has exactly one branch-free
00222  * path per input and keeps the function trivially verifiable. */
00223 static const uint8_t s_deepcut_bits[] = {
00224     [k_lpc_deep_ram_usb_on] = k_dpsbycr_deepcut_ram_usb_on,
00225     [k_lpc_deep_ram_usb_off] = k_dpsbycr_deepcut_ram_usb_off,
00226     [k_lpc_deep_lvd_off] = k_dpsbycr_deepcut_lvd_off,
00227 };
00228
00229 uint8_t value = s_deepcut_bits[deep_power];
00230 if (keep_io) {
00231     value |= k_dpsbycr_iokeep;
00232 }
00233 value |= k_dpsbycr_dpsby;
00234 return value;
00235 }

```

References [k_dpsbycr_deepcut_lvd_off](#), [k_dpsbycr_deepcut_ram_usb_off](#), [k_dpsbycr_deepcut_ram_usb_on](#), [k_dpsbycr_dpsby](#), [k_dpsbycr_iokeep](#), [k_lpc_deep_lvd_off](#), [k_lpc_deep_ram_usb_off](#), and [k_lpc_deep_ram_usb_on](#).

Referenced by [rx_lpc_enter_deep_software_standby\(\)](#).

Here is the caller graph for this function:

8.125.3.2 internal_translate_opcc_mode()

```

rx_err_t internal_translate_opcc_mode (
    rx_lpc_opcc_mode_t mode,
    uint8_t * opcm_bits) [static]

```

Translate OPCCR mode enum to OPCMR[2:0] field value.

Internal helper. The only caller ([rx_lpc_set_operating_power](#)) always passes the address of a stack-local `uint8_t`, so a NULL `opcm_bits` cannot occur from any public API path. No defensive NULL check is therefore required (NASA Rule 5: validate at boundaries, not inside private helpers).

Precondition

`opcm_bits != NULL` (enforced by callers)

Postcondition

`opcm_bits` contains one of `k_opccr_opcm_` constants on success

Since

Version 1.0.0

Definition at line 153 of file `rx_lpc.c`.

```
00154 {
00155     switch (mode) {

Referenced by `rx_lpc_set_operating_power()`.

Here is the caller graph for this function:

8.125.3.3 rx'lpc'enter'deep'software'standby()

```
rx_err_t rx_lpc_enter_deep_software_standby (
    uint32_t wake_mask,
    rx_lpc_deep_power_t deep_power,
    bool keep_io) [nodiscard]
```

Enter Deep Software Standby mode.

Configures `DPSIER0..DPSIER3` from `wake_mask`, sets `DPSBYCR.DEEPCUT`, optionally sets `DPSBYCR.IOKEEP`, sets `SBYCR.SSBY=1` and `DPSBYCR.DPSBY=1` under `PRC1` protection, then executes `WAIT`.

On deep-standby wake the MCU restarts from the reset vector. This function therefore does not return in that case on real hardware; the return path only exists for host-side unit tests. After reset, `rx_lpc_was_deep_standby_wake()` returns true and `rx_lpc_get_wake_flags()` reports which source caused the wake.

Parameters

in	wake_mask	Bitwise OR of rx_lpc_wake_flags_t values; must not be 0
in	deep_power	Deep-cut power configuration (DEEPCUT[1:0])
in	keep_io	If true, set DPSBYCR.IOKEEP=1 so I/O state is retained across the wake-up until the application clears it

Returns

`rx_err_t` Error code (returned only on host builds / on error)

Return values

<code>k_rx_ok</code>	Configuration accepted (host build)
<code>k_rx_err_invalid_arg</code>	<code>wake_mask == 0</code> or contains undefined bits; <code>deep_power</code> not one of rx_lpc_deep_power_t
<code>k_rx_err_not_initialized</code>	rx_lpc_init() has not been called

Precondition

[rx_lpc_init\(\)](#) has been called

`wake_mask != 0` and `(wake_mask & ~k_lpc_wake_all_mask) == 0`

Corresponding pins / peripherals configured by the caller

Postcondition

DPSIER0..DPSIER3 reflect the enabled wake sources

DPSBYCR.DEEPCUT/IOKEEP/DPSBY configured per arguments

`s_last_mode == k_lpc_mode_deep_software_standby` (test-visible)

Warning

This function does not return on real hardware. Any cleanup required after deep standby must be performed at the reset vector / application startup path.

Here is the call graph for this function:

8.125.3.4 rx_lpc_enter_sleep()

```
rx_err_t rx_lpc_enter_sleep (
    void ) [nodiscard]
```

Enter Sleep low-power mode (implementation).

Enter Sleep mode (CPU stop, peripherals run).

Configures SBYCR for Sleep mode (SSBY=0) under PRCR.PRC1 protection, then issues a WAIT instruction to halt the CPU. Peripheral clocks continue running, so any enabled interrupt resumes execution at the instruction following WAIT. Records the last entered mode for post-mortem diagnostics. On the unit-test target the WAIT is skipped.

Note

Not thread-safe. Serialize all rx_lpc_* operations.

Definition at line 338 of file [rx_lpc.c](#).

```

8.125.3.5 rx`lpc`enter`software`standby()

```
rx_err_t rx_lpc_enter_software_standby (
    void ) [nodiscard]
```

Enter Software Standby mode (implementation).

Enter Software Standby mode.

Configures SBYCR.SSBY=1 and DPSBYCR.DPSBY=0 under PRCR.PRC1 so that the upcoming WAIT instruction enters Software Standby (not Sleep, not Deep Standby). Most peripheral clocks are gated off; only configured wake sources (level-sensitive IRQ pins, RTC, watchdog) can resume execution. On the unit-test target the WAIT is skipped.

Note

Not thread-safe. Serialize all rx_lpc_* operations.

Definition at line 374 of file rx_lpc.c.

Here is the call graph for this function:

8.125.3.6 rx_lpc_get_wake_flags()

```
rx_err_t rx_lpc_get_wake_flags (
    uint32_t * flags)  [nodiscard]
```

Read the latched Deep Software Standby wake-source bitfield (implementation).

Read the deep-standby wake flags (DPSIFR0..DPSIFR3).

Copies the cached `s_latched_wake_flags` into the caller-supplied destination. The bitfield has one bit per wake source; the layout is defined by `rx_lpc_wake_t`. Useful after wake to determine which event resumed execution.

Note

Not safe from ISR (acquires no lock but reads driver state that could be torn during init).

Definition at line 503 of file `rx_lpc.c`.

```
00504 {
00505     if (flags == NULL) {
00506         return k_rx_err_invalid_arg;
00507     }
00508     if (s_initialized != k_lpc_initialized) {
00509         return k_rx_err_not_initialized;
00510     }
00511
00512     *flags = s_latched_wake_flags;
00513     return k_rx_ok;
00514 }
```

References [k_lpc_initialized](#), [s_initialized](#), and [s_latched_wake_flags](#).

8.125.3.7 rx_lpc_init()

```
rx_err_t rx_lpc_init (
    void )  [nodiscard]
```

Initialize the Low Power Consumption driver.

Clears the driver's internal state, latches whether the most recent reset was a deep-standby wake-up (so application code can read it back via [rx_lpc_was_deep_standby_wake\(\)](#)), and pre-clears any pending deep-standby wake flags (DPSIFR0..DPSIFR3) that may have been set by the preceding deep-standby exit.

This function does not change the operating power mode; applications should call [rx_lpc_set_operating_power\(\)](#) separately if they want to switch away from the default high-speed mode.

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Driver initialized successfully
----------------------	---------------------------------

Precondition

May be called exactly once per reset
System clocks must already be configured

Postcondition

Driver state tracking is reset
Deep-standby wake flags are cleared

Note

Safe to call from single-threaded startup only.

Since

Version 1.0.0

Definition at line 242 of file [rx_lpc.c](#).

8.125.3.8 rx_lpc_set_operating_power()

```
rx_err_t rx_lpc_set_operating_power (
    rx_lpc_opcc_mode_t mode) [nodiscard]
```

Switch the MCU to a different operating-power-control mode (implementation).

Select the operating power control (OPCCR) mode.

Programs the OPCCR register with the OPCM bits derived from the requested mode (high-speed / middle-speed / low-power, etc.). Performs the standard PRCR.PRC1 unlock-write-lock dance, then bounded-polls the OPCMTSF transition-status flag for completion (max k_opcmtsf_poll_max iterations). On the unit-test target the register write is skipped.

Note

Not thread-safe. Serialize all rx_lpc_* operations.

Definition at line 293 of file rx_lpc.c.

```
00294 {

8.125.3.9 rx`lpc`was`deep`standby`wake()

```
bool rx_lpc_was_deep_standby_wake (
    void ) [nodiscard]
```

Report whether the most recent reset was a Deep Standby wake.

Query whether the last reset was caused by a deep-standby wake.

Returns the cached `s_was_deep_standby_wake` flag latched at boot time. Allows application code to distinguish between a power-on reset and a resume from Deep Software Standby and take different paths (e.g., skip full re-initialization when waking).

Returns

true if the most recent reset was a Deep Software Standby wake; false otherwise (or before [rx_lpc_init\(\)](#) ran).

Precondition

None (function is safe to call at any time after init or before).

Postcondition

No state mutated.

Return value is stable across multiple calls in the same boot session.

Note

Safe from any context including ISR; pure read of static storage.

00011  * All writes to SBYCR, OPCCR, RSTCKCR, and DPSBYCR require PRC1 to be
00012  * unlocked via PRCR (key 0xA5, PRC1=1). The driver unlocks, writes, and
00013  * re-locks PRCR around every such access. PRCR writes are guarded by
00014  * `#ifdef __RX__` so host-side unit tests can exercise the driver without
00015  * hardware-mapped register access.
00016  *
00017  * @par Low-Power Entry Instruction
00018  * All three low-power modes are entered by executing the WAIT instruction
00019  * on RX. SBYCR.SSBY and DPSBYCR.DPSBY are set beforehand to select which
00020  * flavour of low power the WAIT enters:
00021  *
00022  * @verbatim
00023  * SSBY=0, DPSBY=0 -> Sleep (WAIT)
00024  * SSBY=1, DPSBY=0 -> Software Standby (WAIT)
00025  * SSBY=1, DPSBY=1 -> Deep Software Standby (WAIT)
00026  * @endverbatim
00027  */

- PSEL field validation constants.
- enum `mpc_pfs_gpio_t` : `uint8_t` { `k_mpc_pfs_gpio` = 0 }
PFS register value for GPIO mode.
- enum `mpc_pwpr_t` : `uint8_t` { `k_mpc_pwpr_clear` = 0 }
PWPR register control values.
- enum `mpc_port_offset_sentinel_t` : `uint16_t` { `k_mpc_port_offset_invalid` = 0xFFFFU }
Calculate PFS register address for a given port and pin.

Functions

- static `uint16_t` `internal_mpc_port_offset` (`const uint8_t` port)
Resolve a port enum to its PFS-register offset.
- static volatile `uint8_t` * `internal_get_pfs_register` (`const uint8_t` port, `uint8_t` pin)
- static void `internal_mpc_unlock` (void)
Unlock MPC PFS register write protection.
- static void `internal_mpc_lock` (void)
Lock MPC PFS register write protection.
- static `rx_err_t` `internal_write_pfs` (`const uint8_t` port, `uint8_t` pin, `uint8_t` value)
Write value to PFS register with automatic unlock/lock.
- `rx_err_t` `rx_mpc_set_gpio` (`const rx_port_pin_t` pin)
Configure pin for GPIO (General Purpose I/O) function.
- `rx_err_t` `rx_mpc_set_peripheral` (`const rx_mpc_peripheral_config_t` *config)
Configure pin for peripheral function with specified PSEL code.
- `rx_err_t` `rx_mpc_set_mtu_pwm` (`const rx_port_pin_t` pin)
Configure pin for MTU3a timer PWM output (MTIOC).
- `rx_err_t` `rx_mpc_set_mtu_encoder` (`const rx_port_pin_t` pin)
Configure pin for MTU3a encoder/phase counter input (MTCLK).
- `rx_err_t` `rx_mpc_set_tpu_encoder` (`const rx_port_pin_t` pin)
Configure pin for TPU encoder/phase counter input (TCLK).
- `rx_err_t` `rx_mpc_set_adc` (`const rx_port_pin_t` pin)
Configure pin for ADC analog input.
- `rx_err_t` `rx_mpc_set_sci` (`const rx_port_pin_t` pin)
Configure pin for SCI (Serial Communication Interface) UART function.
- `rx_err_t` `rx_mpc_set_riic` (`const rx_port_pin_t` pin)
Configure pin for RIIC (I2C) bus function.
- `rx_err_t` `rx_mpc_set_rspi` (`const rx_port_pin_t` pin)
Configure pin for RSPI (SPI) bus function.
- `rx_err_t` `rx_mpc_set_gptw` (`const rx_port_pin_t` pin)
Configure pin for GPTW complementary PWM output.
- `rx_err_t` `rx_mpc_set_usb_vbus` (`const rx_port_pin_t` pin)
Configure pin for USB VBUS detection.
- `rx_err_t` `rx_mpc_set_irq` (`const rx_port_pin_t` pin)
Configure pin for IRQ (external interrupt) function.

Variables

- static const char *const `s_tag` = "MPC"
Logging tag for MPC module.

8.127.1 Detailed Description

Multi-Function Pin Controller (MPC) Driver Implementation.

Implementation of the MPC driver for RX72N pin multiplexer configuration. This module provides the core functionality for connecting GPIO pins to peripheral functions through the PFS (Pin Function Select) registers.

Implementation Architecture

PWPR Write Protection Sequence

The PFS registers are protected by a two-stage lock. The unlock/lock sequence must be followed exactly:

PFS Register Address Calculation

PFS registers are laid out contiguously in memory with 8 bytes per port:

```

* PFS Base = MPC Base + 0x40 = 0x0008C140
*
* Address = PFS_Base + (port_offset) + pin_number
*
* Port Offsets (8 bytes each):
* Port 0: +0   Port 1: +8   Port 2: +16  Port 3: +24
* Port 4: +32  Port 5: +40  Port 6: +48  Port 7: +56
* Port 8: +64  Port 9: +72  Port A: +80  Port B: +88
* Port C: +96  Port D: +104 Port E: +112 Port J: +144
*
* Example: PB7 (Port B, Pin 7)
* Address = 0x0008C140 + 88 + 7 = 0x0008C19F
*

```

Performance Characteristics

Function	Typical Time	Stack Usage	Notes
rx_mpc_set_gpio()	1.2 us	24 bytes	Direct PFS write
rx_mpc_set_peripheral()	1.5 us	32 bytes	With validation
rx_mpc_set_mtu_pwm()	1.6 us	40 bytes	Calls set_peripheral
Bulk config (10 pins)	15 us	-	Sequential calls

Memory Usage

Category	Size	Description
Code (.text)	~800 bytes	All functions
Constants (.rodata)	4 bytes	Tag string "MPC"
Static data (.data)	0 bytes	None
Stack (max)	40 bytes	Deepest call chain

Thread Safety Analysis

NOT THREAD-SAFE. Critical section analysis:

- [internal_mpc_unlock\(\)](#) -> [internal_write_pfs\(\)](#) -> [internal_mpc_lock\(\)](#)
- This sequence is non-atomic (3 register writes)
- Interrupt or thread switch during unlock leaves PFS unprotected
- Race condition: Thread A unlocks, Thread B unlocks, Thread A writes, Thread B writes (corrupted configuration possible)

Recommended Usage Pattern

```
// Option 1: Configure all pins during single-threaded init
void hardware_init(void) // Called before RTOS starts
{
    rx_mpc_set_peripheral(&pwm_config);
    rx_mpc_set_sci(k_port_b_pin_7);
    // ... all MPC configuration here
}

// Option 2: Use mutex if runtime reconfiguration needed
void configure_pin_safe(const rx_mpc_peripheral_config_t* config)
{
    tx_mutex_get(&mpc_mutex, TX_WAIT_FOREVER);
    rx_mpc_set_peripheral(config);
    tx_mutex_put(&mpc_mutex);
}
```

Error Handling Strategy

- All public functions validate inputs before hardware access
- Errors logged via `rx_log_error()` with descriptive messages
- No partial configuration: if validation fails, no registers modified
- Lock always restored even on error path (no dangling unlock)

NASA Power of 10 Compliance

- Rule 1: [OK] No goto, setjmp, longjmp, recursion
- Rule 2: [OK] Fixed loop bounds (switch/case only, no iteration)
- Rule 3: [OK] No dynamic memory allocation
- Rule 4: [OK] All functions < 60 lines
- Rule 5: [OK] Assertions via `RX_CHECK_*` macros (2+ per function)
- Rule 6: [OK] Variables at smallest scope (function-local)
- Rule 7: [OK] All return values checked and propagated
- Rule 8: [OK] C23 typed enums for all constants
- Rule 9: [WARN] No function pointers (direct calls only)
- Rule 10: [OK] Compiles with `-Wall -Wextra -Werror`

SOLID Principles

- Single Responsibility: Each internal function has one purpose
- Open/Closed: New peripherals added via `set_peripheral()`
- Dependency Inversion: Uses [rx72n_mpc_regs.h](#) abstraction

8.127.2 Enumeration Type Documentation

8.127.2.1 `mpc_pfs_gpio_t`

enum [mpc_pfs_gpio_t](#) : `uint8_t`

PFS register value for GPIO mode.

GPIO mode requires all bits in PFS register to be 0:

- `PSEL[4:0] = 0` (no peripheral function)
- `ISEL = 0` (no interrupt input)
- `ASEL = 0` (digital mode, not analog)

See also

[rx_mpc_set_gpio\(\)](#) Uses this value

Since

Version 1.0.0

Enumerator

k_mpc_pfs_gpio	GPIO mode: all zeros (PSEL=0, ISEL=0, ASEL=0)
----------------	---

Definition at line 357 of file rx_mpc.c.

```
00357      : uint8_t {
00358  k_mpc_pfs_gpio = 0, /**< GPIO mode: all zeros (PSEL=0, ISEL=0, ASEL=0) */
00359 } mpc_pfs_gpio_t;
```

8.127.2.2 mpc`pfs`offset`

```
enum mpc_pfs_offset_t : uint8_t
```

PFS register base offset from MPC structure start.

The PFS registers start at offset 0x40 from MPC base (0x0008C100), which is address 0x0008C140. However, when accessing via the rx_mpc_regs_t struct, we need to account for the structure layout.

This offset is used with pointer arithmetic to calculate PFS register addresses from the mpc() accessor.

Calculation

$$\text{PFS_addr} = (\text{uint8_t}*)\text{mpc}() + \text{k_mpc_pfs_base_offset} + \text{port_offset} + \text{pin}$$

Since

Version 1.0.0

Enumerator

k_mpc_pfs_base_offset	Byte offset from mpc() to P00PFS register (0x40: P00PFS=0x0008C140, base=0x0008C100)
-----------------------	--

Definition at line 232 of file rx_mpc.c.

```
00232      : uint8_t {
00233  k_mpc_pfs_base_offset =
00234    64, /**< Byte offset from mpc() to P00PFS register (0x40: P00PFS=0x0008C140, base=0x0008C100) */
00235 } mpc_pfs_offset_t;
```

8.127.2.3 mpc`pin`constants`

```
enum mpc_pin_constants_t : uint8_t
```

Pin number validation constants for MPC driver.

Defines the valid range for pin numbers within a port. RX72N GPIO ports support up to 8 pins per port (pins 0-7), though not all pins are available on all ports or packages.

See also

[rx_port_constants.h](#) Source of `k_rx_pin_max` definition

Since

Version 1.0.0

Enumerator

<code>k_mpc_min_pin</code>	Minimum valid pin number (always 0)
<code>k_mpc_max_pin</code>	Maximum valid pin number (7 for 8 pins per port)

Definition at line 210 of file [rx_mpc.c](#).

```
00210     : uint8_t {
00211   k_mpc_min_pin = 0,           /**< Minimum valid pin number (always 0) */
00212   k_mpc_max_pin = k_rx_pin_max, /**< Maximum valid pin number (7 for 8 pins per port) */
00213 } mpc_pin_constants_t;
```

8.127.2.4 mpc_port_number_t

```
enum mpc\_port\_number\_t : uint8_t
```

Port number aliases for MPC driver validation.

Maps the generic `rx_port_*` constants to MPC-specific names for use in the switch statement in [internal_get_pfs_register\(\)](#). This provides compile-time verification that all ports are handled.

144-pin LFQFP Package Availability

Port	Available	Notes
0-5	Partial	Some pins available
6-9	Partial	Some pins available (P67, P86/P87 on 144-pin)
A-E	Full	All 8 pins per port
F	Partial	PF0-PF2, PF5 available on 144-pin
G-H	None	Not on 144-pin package
J	Partial	PJ3, PJ5 available on 144-pin

00276 k_mpc_port_f    = k_rx_port_f, /**< Port F (partial on 144-pin: PF0-PF2, PF5) */
00277 k_mpc_port_g    = k_rx_port_g, /**< Port G (not on 144-pin package) */
00278 k_mpc_port_j    = k_rx_port_j, /**< Port J (partial: PJ3, PJ5 on 144-pin) */
00279 } mpc_port_number_t;

```

8.127.2.5 mpc_port_offset_sentinel_t

```
enum mpc_port_offset_sentinel_t : uint16_t
```

Calculate PFS register address for a given port and pin.

Computes the memory address of the Pin Function Select (PFS) register for the specified port and pin combination. Uses a lookup table (switch) to get the port offset, then adds the pin number.

Algorithm Steps

1. Validate pin number is in range [0, 7]
2. Get base address of PFS registers from `mpc()` accessor
3. Look up port offset in switch statement
4. If port invalid, log error and return `nullptr`
5. Return `base + offset + pin`

Address Calculation

```

* PFS_addr = (mpc() + k_mpc_pfs_base_offset) + port_offset + pin
*
* Example: PB7 (Port B, Pin 7)
* = (0x0008C100 + 64) + 88 + 7
* = 0x0008C140 + 88 + 7
* = 0x0008C19F (PB7PFS)
*

```

Precondition

PCLKB clock must be running for MPC register access

Caller has verified channel is in valid range for the target package

Postcondition

No registers modified (read-only address calculation)

Note

Internal function - not exported in header

Port G is explicitly rejected (returns `NULL`) since it is absent on the 144-pin LFQFP package

Port H has no named constant in `rx_port_constants.h`; a raw value in that range falls to the default case and returns `NULL`

Warning

Returned pointer is volatile - must dereference with care
 Caller must still unlock PWPR before writing to the register

Performance

- Execution time: ~200 ns @ 240 MHz (switch lookup + pointer math)
- Stack usage: 8 bytes (local variables)

See also

[mpc\(\)](#) MPC register accessor
[mpc_port_offset_t](#) Port offset constants

Since

Version 1.0.0

Sentinel value indicating a port that is not pin-muxable

Used in the `s_port_pfs_offsets` table to flag ports that are unavailable on the 144-pin LFQFP package (port G, port H). Looking up such a port returns `nullptr` from [internal_get_pfs_register\(\)](#).

Since

Version 1.0.0

Enumerator

<code>k_mpc_port_offset_invalid</code>	Port not available on this package.
--	-------------------------------------

Definition at line 440 of file [rx_mpc.c](#).

```
00440      : uint16_t {
00441  k_mpc_port_offset_invalid = 0xFFFFU, /**< @brief Port not available on this package */
00442 } mpc_port_offset_sentinel_t;
```

8.127.2.6 mpc`port`offset`t

enum [mpc_port_offset_t](#) : `uint16_t`

PFS register byte offsets for each port.

PFS registers are laid out contiguously in memory with 8 bytes allocated per port (one byte per pin), even if not all pins are physically present. These offsets are added to the PFS base address to reach each port's registers.

Memory Layout

```

*   PFS Base (0x0008C140):
*   +0x00: P00PFS - P07PFS (Port 0)
*   +0x08: P10PFS - P17PFS (Port 1)
*   +0x10: P20PFS - P27PFS (Port 2)
*   ...
*   +0x50: PA0PFS - PA7PFS (Port A)
*   +0x58: PB0PFS - PB7PFS (Port B)
*   ...
*   +0x90: PJ0PFS - PJ7PFS (Port J)
*

```

Note

Each port occupies 8 bytes regardless of actual pin count

8.127.3.2 internal`mpc`lock()

```
void internal__mpc_lock (  
    void ) [static]
```

Lock MPC PFS register write protection.

Executes the two-step lock sequence to protect PFS registers after modification. This restores write protection and prevents accidental changes to pin functions.

Lock Sequence (per RX72N Hardware Manual Ch20)

1. Write 0x00 to PWPR (clears PFSWE bit, protects PFS registers)
2. Write 0x80 to PWPR (sets B0WI bit, prevents PFSWE modification)

Timing

- Two 8-bit register writes
- No wait states required between writes
- Total time: ~100 ns @ 240 MHz

Precondition

[internal__mpc_unlock\(\)](#) was called previously
PFS modifications are complete

Postcondition

PWPR.PFSWE = 0 (PFS registers protected)
PWPR.B0WI = 1 (PFSWE bit protected)

Note

Internal function - not exported in header

Example:

```
// Typical usage: unlock, modify PFS, then lock immediately  
internal__mpc_unlock();  
*pfs_reg = k_psel_rspi_clk; // Write peripheral select value  
internal__mpc_lock();       // Restore write protection
```

8.127.3.3 internal_mpc_port_offset()

```
uint16_t internal_mpc_port_offset (
    const uint8_t port) [static]
```

Resolve a port enum to its PFS-register offset.

Lookup table indexed by `k_mpc_port_*` values. Returns `k_mpc_port_offset_invalid` for ports unavailable on this package. Replaces the prior 60+ line switch statement that this function used.

Parameters

in	port	Port enum value (<code>k_mpc_port_0 .. k_mpc_port_j</code>)
----	------	---

Returns

uint16_t PFS port offset, or `k_mpc_port_offset_invalid` if absent

Precondition

None

Postcondition

Return value is either a valid offset or the sentinel

Note

Pure function, no side effects.

Since

Version 1.0.0

Definition at line 463 of file [rx_mpc.c](#).

```

00464 {
00465     switch (port) {
00466         case k_mpc_port_0:

Here is the caller graph for this function:

8.127.3.4 internal'mpc'unlock()

```
void internal_mpc_unlock (
    void ) [static]
```

Unlock MPC PFS register write protection.

Executes the two-step unlock sequence required before writing to any PFS register. The PWPR (Write Protect Register) guards against accidental modification of pin functions.

Unlock Sequence (per RX72N Hardware Manual Ch20)

1. Write 0x00 to PWPR (clears B0WI bit, allows PFSWE modification)
2. Write 0x40 to PWPR (sets PFSWE bit, enables PFS register writes)

Timing

- Two 8-bit register writes
- No wait states required between writes
- Total time: ~100 ns @ 240 MHz

Precondition

MPC module must be active (not in module stop)

Postcondition

PWPR.B0WI = 0 (PFSWE modifiable)

PWPR.PFSWE = 1 (PFS registers writable)

Note

Must call [internal_mpc_lock\(\)](#) after PFS modification!

Internal function - not exported in header

Warning

Not thread-safe - window between unlock and lock is vulnerable

Failing to lock after modification leaves PFS unprotected

Example:

```
// Typical usage: unlock, modify PFS, then lock immediately
internal_mpc_unlock();
*pfs_reg = k_psel_sci_tx; // Write peripheral select value
internal_mpc_lock();
```

See also

[internal_mpc_lock\(\)](#) Must be called after PFS writes

Referenced by [internal_write_pfs\(\)](#).

Here is the call graph for this function:

Here is the caller graph for this function:

8.127.3.5 `internal_write_pfs()`

```

rx_err_t internal_write_pfs (
    const uint8_t port,
    uint8_t pin,
    uint8_t value)  [static]

```

Write value to PFS register with automatic unlock/lock.

Complete PFS modification sequence: calculates register address, unlocks protection, writes the value, and re-locks protection. This function handles the entire write-protected register access pattern.

Algorithm Steps

1. Call [internal_get_pfs_register\(\)](#) to get register address
2. If address is nullptr, return error (no unlock performed)
3. Call [internal_mpc_unlock\(\)](#) to enable PFS writes
4. Write value to PFS register
5. Call [internal_mpc_lock\(\)](#) to protect PFS registers
6. Return success

Execution Flow

Precondition

- PCLKB clock must be running
- Value should be a valid PFS configuration

Postcondition

- PFS register contains specified value
- PWPR is locked (B0WI=1)

Note

- Internal function - not exported in header
- Lock is always executed even on error path (defensive coding)

Warning

- Not thread-safe - the unlock/write/lock sequence is non-atomic

Performance

- Execution time: ~500 ns @ 240 MHz
- Stack usage: 16 bytes

See also

Referenced by [rx_mpc_set_adc\(\)](#), [rx_mpc_set_gpio\(\)](#), [rx_mpc_set_irq\(\)](#), and [rx_mpc_set_peripheral\(\)](#).

Here is the call graph for this function:

Here is the caller graph for this function:

8.127.3.6 rx_mpc_set_adc()

```

rx_err_t rx_mpc_set_adc (
    const rx_port_pin_t pin) [nodiscard]
  
```

Configure pin for ADC analog input.

Configures a pin for analog-to-digital conversion by setting the ASEL bit in the PFS register. This disables the digital input buffer to prevent noise during analog measurement.

Precondition

- PCLKB clock must be running, MPC not in module stop
- pin must encode a valid port/pin combination with analog capability

Postcondition

- PFS register contains k_pfs_asel (0x80) for the specified pin
- PWPR locked after operation

Note

- Thread safety: Not thread-safe
- Sets ASEL bit (0x80) rather than PSEL field
- Also configure S12ADC for actual conversion

```

// Configure P40 (AN000) for ADC analog input
rx_err_t err = rx_mpc_set_adc(RX_PORT_PIN(4, 0));
if (err != k_rx_ok) {
    // handle error
}
  
```

Here is the call graph for this function:

8.127.3.7 rx`mpc`set`gpio()

```

rx_err_t rx_mpc_set_gpio (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for GPIO (General Purpose I/O) function.

Sets the specified pin to GPIO mode by writing 0x00 to its PFS register. This disconnects the pin from all peripheral functions and allows it to be controlled by the PORT registers (PDR, PODR, PIDR).

Implementation Details

1. Extract port and pin number from encoded `rx_port_pin_t`
2. Validate port is in range `[0, J]`
3. Validate pin is in range `[0, 7]`
4. Write 0x00 to PFS register (via `internal_write_pfs`)

Precondition

PCLKB clock running, MPC not in module stop
pin must be a valid `rx_port_pin_t` constant

Postcondition

PFS register = 0x00 (GPIO mode)

PWPR locked after operation

Note

Thread safety: Not thread-safe

Also set PORT PMR bit to 0 for complete GPIO configuration

```
// Configure P30 (port 3, pin 0) for GPIO use
rx_err_t err = rx_mpc_set_gpio(RX_PORT_PIN(3, 0));
if (err != k_rx_ok) {
    // handle error
}
```

Here is the call graph for this function:

8.127.3.8 rx_mpc_set_gptw()

```
rx_err_t rx_mpc_set_gptw (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for GPTW complementary PWM output.

Configure pin for GPTW (General PWM Timer) complementary output.

Convenience wrapper that configures a pin for GPTW operation using PSEL = k_psel_gptw (0x1E). GPTW provides complementary PWM output with dead-time insertion for motor control.

Precondition

PCLKB clock must be running, MPC not in module stop
pin must encode a valid port/pin combination with GPTW multiplexing

Postcondition

PFS register contains `k_psel_gptw` (0x1E) for the specified pin
PWPR locked after operation

Note

Thread safety: Not thread-safe
Used for 4 GPTW channels (0-3) with 8 total pins (IN2 + IN1 per motor)
Phase staggering configured separately via `rx_gptw` driver

```
// Configure motor 2 GPTW IN2 and IN1 pins (Port E)
rx_err_t err = rx_mpc_set_gptw(RX_PORT_PIN(0xE, 3)); // PE3 GTIOC2A (IN2)
if (err == k_rx_ok) {
    err = rx_mpc_set_gptw(RX_PORT_PIN(8, 6)); // P8.6 GTIOC2B (IN1)
}
```

[rx_gptw_init_all_staggered\(\)](#) GPTW channel configuration

Since

Version 1.0.0

Definition at line 1234 of file `rx_mpc.c`.

```
01235 {
01236     /* GPTW pins use PSEL = 0x1E
01237      * Supports 4 GPTW channels (0-3) for motor IN2/IN1 control */
01238     const rx_mpc_peripheral_config_t config = {
01239         .pin = pin,
01240         .psel = k_psel_gptw /* 0x1E - defined in rx_pin_psel_t enum */
01241     };
01242
01243     return rx_mpc_set_peripheral(&config);
01244 }
```

References [k_psel_gptw](#), and [rx_mpc_set_peripheral\(\)](#).

Here is the call graph for this function:

8.127.3.9 rx_mpc_set_irq()

```
rx_err_t rx_mpc_set_irq (
    const rx_port_pin_t pin)  [nodiscard]
```

Configure pin for IRQ (external interrupt) function.

Sets pin function to IRQ mode by writing the ISEL bit (bit 6, value 0x40) directly to the PFS register via [internal_write_pfs\(\)](#). This bypasses [rx_mpc_set_peripheral\(\)](#) because ISEL=0x40 exceeds the 5-bit PSEL field maximum (k_mpc_psel_max = 31).

Mirrors the approach used by [rx_mpc_set_adc\(\)](#) for ASEL (bit 7): both functions write their respective bit directly rather than going through the PSEL validation path.

Algorithm Steps:

1. Extract port number and pin number from encoded pin parameter
2. Validate port in range [0, J]
3. Validate pin in range [0, 7]
4. Write ISEL bit (0x40) to PFS register via [internal_write_pfs\(\)](#)

Precondition

Pin must have IRQ multiplexing capability (P00-P07 for IRQ8-15)
PCLKB clock must be running

Postcondition

Pin ISEL bit (0x40) set in PFS register
PSEL field remains 0 (no peripheral function conflict)

Note

Thread safety: Not thread-safe
Typical pins: P00-P07 for IRQ8-IRQ15 on RX72N
Used by HC-SR04 ultrasonic sensors for echo pulse measurement

```
// Configure P00 for IRQ8 (HC-SR04 echo input)
rx_err_t err = rx_mpc_set_irq(RX_PORT_PIN(0, 0));
if (err != k_rx_ok) {
    // handle error
}
// Then configure ICU for rising/falling edge detection
```

01338 /* Extract port and pin number from type-safe enum */
01339 const uint8_t port = rx_port_from_pin(pin);
01340 const uint8_t pin_num = rx_pin_from_pin(pin);
01341
01342 /* Validate the decoded port and pin are in valid range */
01343 if (port > k_mpc_port_j || pin_num > k_mpc_max_pin) {
01344     rx_log_error(s_tag, "Invalid port or pin number for IRQ function");
01345     return k_rx_err_invalid_arg;
01346 }
01347
01348 /* IRQ mode: Set ISEL = 1 (bit 6) to enable IRQ input function.
01349 * This is NOT a PSEL value; k_pfs_isel is 0x40 which exceeds the 5-bit
01350 * PSEL field. Write directly like rx_mpc_set_adc() does for ASEL.
01351 * Typical IRQ pins: P00-P07 (IRQ8-IRQ15) for HC-SR04 echo measurement. */
01352 return internal_write_pfs(port, pin_num, k_pfs_isel);
01353 }

```

References [internal_write_pfs\(\)](#), [k_mpc_max_pin](#), [k_mpc_port_j](#), [k_pfs_isel](#), and [s_tag](#).

Here is the call graph for this function:

8.127.3.10 rx`mpc`set`mtu`encoder()

```

rx_err_t rx_mpc_set_mtu_encoder (
    const rx_port_pin_t pin) [nodiscard]

```

Configure pin for MTU3a encoder/phase counter input (MTCLK).

Convenience wrapper that configures a pin for MTU external clock / phase counting mode using PSEL = k_psel_mtu_phase (0x02). Used for quadrature encoders on pins that expose MTCLKA/B/C/D.

Precondition

PCLKB clock must be running, MPC not in module stop
pin must encode a valid port/pin combination supported by MTCLK input

Postcondition

PFS register contains k_psel_mtu_phase (0x02) for the specified pin
PWPR locked after operation

Note

Thread safety: Not thread-safe

Configure both Phase A and Phase B pins for proper operation

```
// Configure P24 and P25 for MTU phase counting (MTCLKA/B)
rx_err_t err = rx_mpc_set_mtu_encoder(RX_PORT_PIN(2, 4));
if (err == k_rx_ok) {
    err = rx_mpc_set_mtu_encoder(RX_PORT_PIN(2, 5));
}
```

00908     /* MTU external clock / phase counting pins use PSEL = 0x02 on every
00909     * RX72N MTCLK candidate pin. See RX72N Group Hardware Manual
00910     * (R01UH0824EJ0111), chapter 23 "Multi-Function Pin Controller (MPC)",
00911     * Tables 23.5 / 23.6 / 23.17 / 23.19 -- every row that selects MTCLKA,
00912     * MTCLKB, MTCLKC, or MTCLKD on a 144-pin LFQFP pin is PSEL = 000010b.
00913     * The old value 0x03 was wrong -- it caused MTU TCNT to stay at 0x0000
00914     * because no MTCLK source was actually connected through the PFS mux.
00915     *
00916     * Common STAR pins:
00917     * P24/P25 (Motor 0 front-right MTCLKA/B)
00918     * PA1/PC5 (Motor 1 front-left MTCLKC/D)
00919     */
00920     const rx_mpc_peripheral_config_t config = {.pin = pin, .psel = k_psel_mtu_phase};
00921
00922     return rx_mpc_set_peripheral(&config);
00923 }
```

References [k_psel_mtu_phase](#), and [rx_mpc_set_peripheral\(\)](#).

Here is the call graph for this function:

8.127.3.11 rx_mpc_set_mtu_pwm()

```
rx_err_t rx_mpc_set_mtu_pwm (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for MTU3a timer PWM output (MTIOC).

Convenience wrapper that configures a pin for MTU I/O compare output using PSEL = [k_psel_mtu_ioc](#) (0x01). Commonly used for motor PWM.

Precondition

PCLKB clock must be running, MPC not in module stop
pin must encode a valid port/pin combination supported by MTU MTIOC

Postcondition

PFS register contains k_psel_mtu_ioc (0x01) for the specified pin
PWPR locked after operation

Note

Thread safety: Not thread-safe

STAR project uses GPTW for motor PWM (see [rx_mpc_set_gptw\(\)](#), PSEL = k_psel_gptw (0x1E)), not MTU

```
// Configure P14 for MTU3 PWM output (MTIOCA)
rx_err_t err = rx_mpc_set_mtu_pwm(RX_PORT_PIN(1, 4));
if (err != k_rx_ok) {
    // handle error
}
```

References [k_psel_mtu_ioc](#), and [rx_mpc_set_peripheral\(\)](#).

Here is the call graph for this function:

8.127.3.12 rx_mpc_set_peripheral()

```
rx_err_t rx_mpc_set_peripheral (
    const rx_mpc_peripheral_config_t * config)  [nodiscard]
```

Configure pin for peripheral function with specified PSEL code.

Core function for peripheral pin configuration. Writes the specified PSEL value to the pin's PFS register, connecting it to a peripheral.

Implementation Details

1. Validate config pointer is not nullptr
2. Validate PSEL value is in range [0, 31]
3. Extract port and pin from config->pin
4. Validate extracted values
5. Write PSEL to PFS register (via internal_write_pfs)

Precondition

config must be non-NULL with valid fields
PCLKB clock running

Postcondition

PFS register contains config->psel
PWPR locked after operation

Note

Thread safety: Not thread-safe
Also set PORT PMR bit to 1 for peripheral mode

```
// Configure PA0 for RSPI clock (PSEL = 0x0D)
const rx_mpc_peripheral_config_t cfg = {
    .pin = RX_PORT_PIN(0xA, 0),
    .psel = 0x0D,
};
rx_err_t err = rx_mpc_set_peripheral(&cfg);
if (err != k_rx_ok) {
    // handle error
}
```

Here is the call graph for this function:

Here is the caller graph for this function:

8.127.3.13 rx_mpc_set_riic()

```
rx_err_t rx_mpc_set_riic (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for RIIC (I2C) bus function.

Convenience wrapper that configures a pin for RIIC operation using PSEL = k_psel_riic_scl (0x0F). Works for both SCL and SDA pins.

Unlike [rx_mpc_set_gptw\(\)](#), this function also sets PORT.PMR=1 for the pin before returning – RIIC cannot drive SDA/SCL while PMR=0 and the immediate-vs-deferred PMR trade-off differs from the motor-PWM case:

Peripheral	When to raise PMR	Reason
GPTW/PWM	AFTER timer is running	Push-pull drive: an un-
	(rx_gptw_init_pwm handles	initialized output could
	this after rx_gptw_start)	momentarily glitch
		DRV8263H H-bridge inputs
		to Vm/2 during the
		GTIOR reset state window.
RIIC/I2C	IMMEDIATELY after PFS	Open-drain + external
	(here, inside this wrapper)	pull-ups: idle bus is
		both lines high (3.3V);
		routing an un-initialized
		RIIC just leaves the
		pull-ups floating the
		lines high. No hazard.

Without PMR=1 on the RIIC pins, rx72n peripheral bits still toggle internally but the pad stays disconnected from RIIC; every Start condition times out with k_rx_err_timeout (0x108) at the first [riic_write\(\)](#)/[riic_read\(\)](#) call. Discovered 2026-04-22: production imu_task saw tight "[ERROR] [RIIC] Start condition timeout" loops while imu_test/main.c (which sets PMR=1 at line 227 before calling its own [riic_init\(\)](#)) talked to BNO055 + BMP280 cleanly on the same board.

Precondition

PCLKB clock must be running, MPC not in module stop
pin must encode a valid port/pin combination with RIIC multiplexing

Postcondition

PFS register contains k_psel_riic_scl (0x0F) for the specified pin
PORT.PMR bit for the pin is set (pin routed to RIIC peripheral)
PWPR locked after operation

Note

Thread safety: Not thread-safe

Configure both SCL and SDA pins; external pull-ups required

```
// Configure P12 (SCL) and P13 (SDA) for RIIC0
rx_err_t err = rx_mpc_set_riic(RX_PORT_PIN(1, 2));
if (err == k_rx_ok) {
    err = rx_mpc_set_riic(RX_PORT_PIN(1, 3));
}
```

8.127.3.14 rx_mpc_set_rspi()

```
rx_err_t rx_mpc_set_rspi (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for RSPI (SPI) bus function.

Convenience wrapper that configures a pin for RSPI operation using PSEL = k_psel_rspi_clk (0x0D). Works for all SPI signals (CLK, COPI, CIPO, SSL).

Precondition

PCLKB clock must be running, MPC not in module stop
pin must encode a valid port/pin combination with RSPI multiplexing

Postcondition

PFS register contains k_psel_rspi_clk (0x0D) for the specified pin
PWPR locked after operation

Note

Thread safety: Not thread-safe

Configure all 4 SPI pins (CLK, COPI, CIPO, CS)

Uses OSHWA-approved inclusive terminology

```
// Configure PA0-PA4 for RSPI0 (CLK, COPI, CIPO, SSL0, SSL1)
rx_err_t err = rx_mpc_set_rspi(RX_PORT_PIN(0xA, 0)); // CLK
if (err == k_rx_ok) {
    err = rx_mpc_set_rspi(RX_PORT_PIN(0xA, 1)); // COPI
}
```

Here is the call graph for this function:

8.127.3.15 rx`mpc`set`sci()

```
rx_err_t rx_mpc_set_sci (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for SCI (Serial Communication Interface) UART function.

Convenience wrapper that configures a pin for SCI UART operation using `PSEL = k_psel_sci_tx (0x0A)`. Works for both TXD and RXD pins.

Precondition

PCLKB clock must be running, MPC not in module stop

pin must encode a valid port/pin combination with SCI multiplexing

Postcondition

PFS register contains `k_psel_sci_tx` (0x0A) for the specified pin
 PWPR locked after operation

Note

Thread safety: Not thread-safe
 Configure both TXD and RXD pins for bidirectional UART

```
// Configure PB7 for SCI9 TXD
rx_err_t err = rx_mpc_set_sci(RX_PORT_PIN(0xB, 7));
if (err != k_rx_ok) {
    // handle error
}
```

Here is the call graph for this function:

Here is the caller graph for this function:

8.127.3.16 rx`mpc`set`tpu`encoder()

```
rx_err_t rx_mpc_set_tpu_encoder (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for TPU encoder/phase counter input (TCLK).

Convenience wrapper that configures a pin for TPU external clock input (TCLKA/B/C/D). Picks the correct PSEL value based on which port the pin is on, because RX72N uses two different alternate-function slots for the SAME TCLK signal depending on candidate:

- Port C pins (PC0/PC1/PC2/PC3) use PSEL = 0x03 (k_psel_tpu_clk_portc)
- Port 1 / Port A / Port B pins use PSEL = 0x04 (k_psel_tpu_clk_alt)

Reference: RX72N Group Hardware Manual (R01UH0824EJ0111), chapter 23 "Multi-Function Pin Controller (MPC)". TCLK rows in Table 23.19 (Port C) use PSEL = 000011b, while TCLK rows in Tables 23.5 (P1x), 23.17 (PAx), and 23.18 (PBx) use PSEL = 000100b. Before this split, every TPU pin was configured with PSEL=0x03, which silently misconfigured the non-Port-C halves of STAR's rear-wheel encoders (PA3 for Motor 2 Phase B, PB3 for Motor 3 Phase B) so those edges were never counted.

Precondition

PCLKB clock must be running, MPC not in module stop

pin must encode a valid port/pin combination supported by TCLK input

Postcondition

PFS register contains the correct TPU-TCLK PSEL for that pin's port

PWPR locked after operation

Note

Thread safety: Not thread-safe

Configure both Phase A and Phase B pins for proper operation

```
// Configure PC2 (TCLKA) and PA3 (TCLKB) for Motor 2 rear-left encoder
rx_err_t err = rx_mpc_set_tpu_encoder(RX_PORT_PIN(0xC, 2)); // -> 0x03
if (err == k_rx_ok) {
    err = rx_mpc_set_tpu_encoder(RX_PORT_PIN(0xA, 3));      // -> 0x04
}
```

Here is the call graph for this function:

8.127.3.17 rx_mpc_set_usb_vbus()

```
rx_err_t rx_mpc_set_usb_vbus (
    const rx_port_pin_t pin) [nodiscard]
```

Configure pin for USB VBUS detection.

Configure pin for USB VBUS detection function.

Convenience wrapper that configures a pin for USB VBUS detection using PSEL = 0x11. Required for USB CDC enumeration and power monitoring.

Precondition

PCLKB clock must be running, MPC not in module stop
pin must encode a valid port/pin combination with USB VBUS multiplexing

Postcondition

PFS register contains k_psel_usb_vbus (0x11) for the specified pin
PWPR locked after operation

Note

Thread safety: Not thread-safe
Active-high VBUS detect (pin = 1 when 5V present)
Also requires USB PHY and controller configuration

```
// Configure P16 for USB0_VBUS detection
rx_err_t err = rx_mpc_set_usb_vbus(RX_PORT_PIN(1, 6));
if (err != k_rx_ok) {
    // handle error
}
```

8.127.4 Variable Documentation

8.127.4.1 s`tag

```
const char* const s_tag = "MPC" [static]
```

Logging tag for MPC module.

Static constant string used as the tag parameter for all `rx_log_*`() calls within this module. Provides consistent identification of MPC-related log messages in debug output.

Value: "MPC"

Memory: 4 bytes in .rodata section

Note

Statically allocated, never modified

00095 * | Bulk config (10 pins) | 15 us | - | Sequential calls |
00096 *
00097 * @par Memory Usage
00098 * | Category | Size | Description |
00099 * |-----|-----|-----|
00100 * | Code (.text) | ~800 bytes | All functions |
00101 * | Constants (.rodata) | 4 bytes | Tag string "MPC" |
00102 * | Static data (.data) | 0 bytes | None |
00103 * | Stack (max) | 40 bytes | Deepest call chain |
00104 *
00105 * @par Thread Safety Analysis
00106 * **NOT THREAD-SAFE.** Critical section analysis:
00107 * - internal_mpc_unlock() -> internal_write_pfs() -> internal_mpc_lock()
00108 * - This sequence is non-atomic (3 register writes)
00109 * - Interrupt or thread switch during unlock leaves PFS unprotected
00110 * - Race condition: Thread A unlocks, Thread B unlocks, Thread A writes,
00111 *   Thread B writes (corrupted configuration possible)
00112 *
00113 * @par Recommended Usage Pattern
00114 * @code{.c}
00115 * // Option 1: Configure all pins during single-threaded init
00116 * void hardware_init(void) // Called before RTOS starts
00117 * {
00118 *     rx_mpc_set_peripheral(&pwm_config);
00119 *     rx_mpc_set_sci(k_port_b_pin_7);
00120 *     // ... all MPC configuration here
00121 * }
00122 *
00123 * // Option 2: Use mutex if runtime reconfiguration needed
00124 * void configure_pin_safe(const rx_mpc_peripheral_config_t* config)
00125 * {
00126 *     tx_mutex_get(&mpc_mutex, TX_WAIT_FOREVER);
00127 *     rx_mpc_set_peripheral(config);
00128 *     tx_mutex_put(&mpc_mutex);
00129 * }
00130 * @endcode
00131 *
00132 * @par Error Handling Strategy
00133 * - All public functions validate inputs before hardware access
00134 * - Errors logged via rx_log_error() with descriptive messages
00135 * - No partial configuration: if validation fails, no registers modified
00136 * - Lock always restored even on error path (no dangling unlock)
00137 *
00138 * @par NASA Power of 10 Compliance
00139 * - **Rule 1**: [OK] No goto, setjmp, longjmp, recursion
00140 * - **Rule 2**: [OK] Fixed loop bounds (switch/case only, no iteration)
00141 * - **Rule 3**: [OK] No dynamic memory allocation
00142 * - **Rule 4**: [OK] All functions < 60 lines
00143 * - **Rule 5**: [OK] Assertions via RX_CHECK_* macros (2+ per function)
00144 * - **Rule 6**: [OK] Variables at smallest scope (function-local)
00145 * - **Rule 7**: [OK] All return values checked and propagated
00146 * - **Rule 8**: [OK] C23 typed enums for all constants
00147 * - **Rule 9**: [WARN] No function pointers (direct calls only)
00148 * - **Rule 10**: [OK] Compiles with -Wall -Wextra -Werror
00149 *
00150 * @par SOLID Principles
00151 * - **Single Responsibility**: Each internal function has one purpose
00152 * - **Open/Closed**: New peripherals added via set_peripheral()
00153 * - **Dependency Inversion**: Uses rx72n_mpc_regs.h abstraction
00154 *

00383  * @brief Calculate PFS register address for a given port and pin
00384  *
00385  * @details
00386  * Computes the memory address of the Pin Function Select (PFS) register
00387  * for the specified port and pin combination. Uses a lookup table (switch)
00388  * to get the port offset, then adds the pin number.
00389  *
00390  * @par Algorithm Steps
00391  * 1. Validate pin number is in range [0, 7]
00392  * 2. Get base address of PFS registers from mpc() accessor
00393  * 3. Look up port offset in switch statement
00394  * 4. If port invalid, log error and return nullptr
00395  * 5. Return base + offset + pin
00396  *
00397  * @par Address Calculation
00398  * @verbatim
00399  *   PFS_addr = (mpc() + k_mpc_pfs_base_offset) + port_offset + pin
00400  *
00401  *   Example: PB7 (Port B, Pin 7)
00402  *   = (0x0008C100 + 64) + 88 + 7
00403  *   = 0x0008C140 + 88 + 7
00404  *   = 0x0008C19F (PB7PFS)
00405  * @endverbatim
00406  *
00407  *
00408  *
00409  * @pre PCLKB clock must be running for MPC register access
00410  * @pre Caller has verified channel is in valid range for the target package
00411  *
00412  * @post No registers modified (read-only address calculation)
00413  *
00414  * @note Internal function - not exported in header
00415  * @note Port G is explicitly rejected (returns NULL) since it is absent on the 144-pin LFQFP package
00416  * @note Port H has no named constant in rx_port_constants.h; a raw value in that range falls to the default case and
    returns NULL
00417  *
00418  * @warning Returned pointer is volatile - must dereference with care
00419  * @warning Caller must still unlock PWPR before writing to the register
00420  *
00421  * @par Performance
00422  * - Execution time: ~200 ns @ 240 MHz (switch lookup + pointer math)
00423  * - Stack usage: 8 bytes (local variables)
00424  *
00425  * @see mpc() MPC register accessor

01071 * PSEL = k_psel_riic_scl (0x0F). Works for both SCL and SDA pins.
01072 *
01073 * Unlike rx_mpc_set_gptw(), this function also sets PORT.PMR=1 for the
01074 * pin before returning -- RIIC cannot drive SDA/SCL while PMR=0 and the
01075 * immediate-vs-deferred PMR trade-off differs from the motor-PWM case:
01076 *
01077 * | Peripheral | When to raise PMR | Reason |
01078 * |-----|-----|-----|
01079 * | GPTW/PWM | AFTER timer is running | Push-pull drive: an un-
01080 * | | (rx_gptw_init_pwm handles | initialized output could
01081 * | | this after rx_gptw_start) | momentarily glitch
01082 * | | | DRV8263H H-bridge inputs
01083 * | | | to Vm/2 during the
01084 * | | | GTIOR reset state window.
01085 * | RIIC/I2C | IMMEDIATELY after PFS | Open-drain + external
01086 * | | (here, inside this wrapper) | pull-ups: idle bus is
01087 * | | | both lines high (3.3V);
01088 * | | | routing an un-initialized
01089 * | | | RIIC just leaves the
01090 * | | | pull-ups floating the
01091 * | | | lines high. No hazard.
01092 *
01093 * Without PMR=1 on the RIIC pins, rx72n peripheral bits still toggle
01094 * internally but the pad stays disconnected from RIIC; every Start
01095 * condition times out with k_rx_err_timeout (0x108) at the first
01096 * riic_write()/riic_read() call. Discovered 2026-04-22: production
01097 * imu_task saw tight "[ERROR] [RIIC] Start condition timeout" loops while
01098 * imu_test/main.c (which sets PMR=1 at line 227 before calling its own
01099 * riic_init()) talked to BNO055 + BMP280 cleanly on the same board.
01100 *
01101 *
01102 *
01103 * @pre PCLKB clock must be running, MPC not in module stop

Include dependency graph for rx_mtu.c:
```

Enumerations

- enum `mtu_constants_t` : `uint8_t` { `k_mtu_max_channels` = 8 }
MTU general constants.
- enum `mtu_module_stop_bits_t` : `uint8_t` { `k_mtu_mstpa_mtu0_4` = 9 }
MTU module stop bit position in MSTPCRA.
- enum `mtu_bit_constants_t` : `uint32_t` { `k_mtu_bit_one` = 1UL }
Bit manipulation constants.
- enum `mtu_period_constants_t` : `uint16_t` { `k_mtu_period_divisor` = 2 , `k_mtu_period_max` = 0xFFFF , `k_mtu_period_min` = 10 , `k_mtu_period_zero` = 0 }
Period calculation constants.
- enum `mtu_tior_shift_t` : `uint8_t` { `k_mtu_tior_low_shift` = 0 , `k_mtu_tior_high_shift` = 4 }
TIOR register shift positions.
- enum `mtu_tior_mask_t` : `uint8_t` { `k_mtu_tior_keep_high_clear_low` = 0xF0 , `k_mtu_tior_keep_low_clear_high` = 0x0F }
TIOR register clear-masks (value AND'd against TIOR to zero a nibble).
- enum `mtu_tior_disabled_t` : `uint8_t` { `k_mtu_tior_disabled` = 0x00 }
TIOR output disabled value.
- enum `mtu_duty_constants_t` : `uint8_t` { `k_mtu_duty_min` = 0 , `k_mtu_duty_max` = 100 , `k_mtu_duty_divisor` = 100 }
Duty cycle calculation constants.

Functions

- static volatile void * `internal_get_mtu_base` (const `rx_mtu_channel_t` channel)
Get MTU channel register base address.
- static bool `internal_is_valid_channel` (const `rx_mtu_channel_t` channel)
Check if MTU channel is valid.
- static `rx_err_t` `internal_clear_tstr_bit` (volatile `rx_mtu_tstr_regs_t` *tstr, const `uint8_t` mask)
Clear a counter-start bit in a TSTR register and verify it cleared.
- static `rx_err_t` `internal_calculate_period` (const `uint32_t` frequency_hz, `uint16_t` *period)
Calculate period register value from frequency.
- static volatile `uint16_t` * `internal_get_tgr_register` (volatile `rx_mtu_channel_regs_t` *mtu, const `rx_mtu_output_t` output)
Get TGR register pointer for output channel.
- static `rx_err_t` `internal_set_duty_raw_mtu` (volatile `rx_mtu_channel_regs_t` *mtu, const `rx_mtu_output_t` output, const `uint16_t` duty_count)
Write a raw duty count to the TGR register for the specified output.
- `rx_err_t` `rx_mtu_init_pwm` (const `rx_mtu_channel_t` channel, const `rx_mtu_config_t` *config)
Initialize MTU channel for PWM operation.
- `rx_err_t` `rx_mtu_set_duty` (const `rx_mtu_channel_t` channel, `rx_mtu_output_t` output, const float duty_percent)
Set PWM duty cycle as a floating-point percentage.
- `rx_err_t` `rx_mtu_set_duty_raw` (const `rx_mtu_channel_t` channel, `rx_mtu_output_t` output, `uint16_t` duty_count)
Set PWM duty cycle using a raw 16-bit timer count.
- `rx_err_t` `rx_mtu_get_duty` (const `rx_mtu_channel_t` channel, const `rx_mtu_output_t` output, float *duty_percent)
Read the current PWM duty cycle as a floating-point percentage.
- `rx_err_t` `rx_mtu_get_period` (const `rx_mtu_channel_t` channel, `uint16_t` *period_count)
Get PWM period count for MTU channel.

- rx_err_t [rx_mtu_enable_output](#) (const [rx_mtu_channel_t](#) channel, [rx_mtu_output_t](#) output, const bool enable)
Enable or disable a single MTU PWM output pin.
- rx_err_t [rx_mtu_start](#) (const [rx_mtu_channel_t](#) channel)
Start MTU counter (begin PWM generation).
- rx_err_t [rx_mtu_stop](#) (const [rx_mtu_channel_t](#) channel)
Stop MTU counter (halt PWM generation).
- rx_err_t [rx_mtu_deinit](#) (const [rx_mtu_channel_t](#) channel)
Deinitialize an MTU PWM channel.

Variables

- static const char *const [s_tag](#) = "MTU"
- static bool [s_mtu_initialized](#) [[k_mtu_max_channels](#)] = {false}
Track which MTU channels have been initialized.
- static uint16_t [s_mtu_period](#) [[k_mtu_max_channels](#)] = {}
Cached PWM period register values for each MTU channel.

8.129.1 Detailed Description

MTU PWM Driver Implementation for RX72N.

Production-grade implementation of the Multi-Function Timer Unit (MTU) peripheral driver for PWM generation on RX72N. The MTU provides 16-bit timer resolution with multiple outputs per channel.

8.129.1.1 Module Architecture

The MTU peripheral is organized as:

- MTU0-MTU4: First group, controlled by MSTPCRA.MSTPA9 and TSTRA
- MTU6-MTU7: Second group, controlled by MSTPCRA.MSTPA9 and TSTRB
- Note: MTU5 exists but is excluded from general PWM use

8.129.1.2 PWM Mode 1 (Triangle Wave - Center-Aligned)

This driver configures MTU in PWM Mode 1 for center-aligned PWM:

- Counter counts up from 0 to TGRA (period), then down to 0
- Compare matches on TGRB/TGRC/TGRD control duty cycle
- Symmetric PWM pulses reduce harmonic content
- Lower EMI compared to edge-aligned PWM

PWM Timing Diagram:

8.129.1.3 Frequency and Resolution

Calculation:

$$\text{Period} = \frac{f_{PCLKA}}{2 \times f_{PWM}}$$

Example: 20kHz PWM with PCLKA=120MHz:

Parameter	Value	Notes
Period	3000 counts	120MHz / (2 x 20kHz)
Resolution	~11.5 bits	$\log_2(3000) \sim 11.5$
Duty range	0-3000	0-100% in integer counts
Step size	0.033%	100% / 3000

8.129.1.4 Register Base Addresses

Channel	Base Address	TSTR Register
MTU0	0x000C1300	TSTRA (bit 0)
MTU1	0x000C1380	TSTRA (bit 1)
MTU2	0x000C1400	TSTRA (bit 2)
MTU3	0x000C1200	TSTRA (bit 6)
MTU4	0x000C1201	TSTRA (bit 7)
MTU6	0x000C1A00	TSTRB (bit 6)
MTU7	0x000C1A01	TSTRB (bit 7)

8.129.1.5 Static Variables

Variable	Type	Purpose
s_mtu_initialized[]	bool↔ [8]	Track which channels are initialized
s_mtu_period[]	uint16_t↔ [8]	Cache period values for duty calculation
s_tag	const char*	Log tag "MTU"

NASA Power of 10 Compliance:

Rule	Status	Implementation
1. Simple control flow	↔ [OK]↔	No goto/setjmp/recursion
2. Fixed loop bounds	↔ [OK]↔	No unbounded loops
3. No dynamic allocation	↔ [OK]↔	All static, zero malloc
4. Small functions	↔ [OK]↔	All functions < 60 lines
5. Assertions	↔ [OK]↔	RX_VALIDATE_PTR, RX_VALIDATE_INIT
6. Narrow scope	↔ [OK]↔	Static variables, internal functions
7. Check return values	↔ [OK]↔	All rx_err_t returns checked
8. Limited preprocessor	↔ [OK]↔	C23 typed enums for constants
9. Pointer restrictions	↔ [OK]↔	Single-level pointers
10. Compiler warnings	↔ [OK]↔	Clean with -Wall -Wextra -Werror

SOLID Principles:

Single Responsibility: This file handles ONLY MTU PWM generation. Motor control logic and encoder reading are in separate modules.

00145 } mtu_period_constants_t;
```

8.129.2.6 mtu_tior_disabled_t

```
enum mtu_tior_disabled_t : uint8_t
```

TIOR output disabled value.

Enumerator

k_mtu_tior_disabled	Output disabled
---------------------	-----------------

Definition at line 166 of file [rx_mtu.c](#).

```
00166      : uint8_t {
00167  k_mtu_tior_disabled = 0x00, /**< Output disabled */
00168 } mtu_tior_disabled_t;
```

8.129.2.7 mtu_tior_mask_t

```
enum mtu_tior_mask_t : uint8_t
```

TIOR register clear-masks (value AND'd against TIOR to zero a nibble).

The low nibble (bits 3:0) controls MTIOCA/MTIOCC and the high nibble (bits 7:4) controls MTIOCB/↵ MTIOCD. To zero the low nibble without disturbing the high nibble you AND with 0xF0; to zero the high nibble you AND with 0x0F. Names therefore describe which nibble is kept.

Enumerator

k_mtu_tior_keep_high_clear_low	AND-mask: keep high nibble, clear low (MTIOCA/C)
k_mtu_tior_keep_low_clear_high	AND-mask: keep low nibble, clear high (MTIOCB/D)

Definition at line 160 of file [rx_mtu.c](#).

```
00160      : uint8_t {
00161  k_mtu_tior_keep_high_clear_low = 0xF0, /**< AND-mask: keep high nibble, clear low (MTIOCA/C) */
00162  k_mtu_tior_keep_low_clear_high = 0x0F, /**< AND-mask: keep low nibble, clear high (MTIOCB/D) */
00163 } mtu_tior_mask_t;
```

8.129.2.8 mtu_tior_shift_t

```
enum mtu_tior_shift_t : uint8_t
```

TIOR register shift positions.

Enumerator

k_mtu_tior_low_shift	Low nibble shift (MTIOCA/MTIOCC)
k_mtu_tior_high_shift	High nibble shift (MTIOCB/MTIOCD)

Definition at line 148 of file [rx_mtu.c](#).

00149  k_mtu_tior_low_shift = 0, /**< Low nibble shift (MTIOCA/MTIOCC) */
00150  k_mtu_tior_high_shift = 4, /**< High nibble shift (MTIOCB/MTIOCD) */
00151 } mtu_tior_shift_t;
```

8.129.3 Function Documentation

8.129.3.1 internal`calculate`period()

```
rx_err_t internal_calculate_period (
    const uint32_t frequency_hz,
    uint16_t * period) [static]
```

Calculate period register value from frequency.

Converts desired PWM frequency to the TGRA (period) register value for PWM Mode 1 (triangle wave, center-aligned).

8.129.3.2 Calculation

$$\text{period} = \frac{f_{PCLKA}}{2 \times f_{PWM}}$$

Where:

- $f_{PCLKA} = 120 \text{ MHz}$
- Divisor of 2 accounts for up/down counting in triangle mode

8.129.3.3 Valid Frequency Range

Frequency	Period	Status
< 915 Hz	> 65535	Rejected (overflow)
915 Hz - 6 MHz	10-65535	Valid
> 6 MHz	< 10	Rejected (too small)

Precondition

PCLKA configured to 120 MHz
period points to valid uint16_t storage

Postcondition

*period contains value in range [10, 65535]

Note

16-bit resolution limits frequency range compared to 32-bit GPTW

8.129.3.4 internal_clear_tstr_bit()

```
rx_err_t internal_clear_tstr_bit (
    volatile rx_mtu_tstr_regs_t * tstr,
    const uint8_t mask) [static]
```

Clear a counter-start bit in a TSTR register and verify it cleared.

Performs a read-modify-write on the TSTR register to clear the specified bit mask, then reads back the register to confirm the bit was cleared. Returns a hardware error if the bit is still set after the write, which can indicate a peripheral fault.

Precondition

tstr points to a valid TSTRA or TSTRB hardware register
 mask is a valid CSTn bit mask from [mtu_tstr_bits_t](#)

Postcondition

Specified CSTn bit is cleared (counter stopped) on success
 tstr register unchanged on error

Note

Not thread-safe: caller must ensure exclusive access to TSTR register
 Readback verification adds one extra register read cycle

8.129.3.5 internal`get`mtu`base()

```
volatile void * internal__get__mtu__base (
    const rx\_mtu\_channel\_t channel) [static]
```

Get MTU channel register base address.

Maps an MTU channel enumeration to its hardware register base address. The MTU peripheral has sparse channel numbering (0-4, 6-7 with no 5).

8.129.3.6 Memory Map

Channel	Base Address	Description
MTU0	0x000C1290	16-bit timer with 4 outputs
MTU1	0x000C1290	16-bit timer with 2 outputs
MTU2	0x000C1292	16-bit timer with 2 outputs
MTU3	(nullptr)	sparse layout, cannot use standard struct API
MTU4	(nullptr)	sparse layout, cannot use standard struct API
MTU6	(nullptr)	interleaved layout, use mtu6() with rx_mtu3_channel_regs_t
MTU7	(nullptr)	interleaved layout, use mtu7() with direct register offsets

MTU3, MTU4, MTU6, and MTU7 all have an interleaved register layout that is incompatible with [rx_mtu_channel_regs_t](#). Use [mtu3\(\)](#)/[mtu6\(\)](#) with [rx_mtu3_channel_regs_t](#) directly; this function returns nullptr for all four channels to prevent callers from applying the wrong struct offset mapping.

Precondition

Module clock must be enabled before accessing returned pointer

Postcondition

Returned pointer valid for hardware access

No hardware state modified

Note

Thread-safe: Returns constant address

Returns void* to accommodate different register structure types

8.129.3.9 internal`set`duty`raw`mtu()

```

rx_err_t internal_set_duty_raw_mtu (
    volatile rx_mtu_channel_regs_t * mtu,
    const rx_mtu_output_t output,
    const uint16_t duty_count) [static]

```

Write a raw duty count to the TGR register for the specified output.

Resolves the TGR register pointer for the requested output via `internal_get_tgr_register()` and writes `duty_count` to it. The write is buffered by hardware and takes effect at the next PWM period boundary, producing a glitch-free duty cycle update.

Algorithm:

1. Validate mtu pointer is non-NULL
2. Resolve TGR register pointer for output via `internal_get_tgr_register()`
3. Validate resolved TGR pointer is non-NULL
4. Write `duty_count` to TGR register

Precondition

mtu points to a valid, initialized MTU channel register block
 duty_count has been validated or clamped by the caller to [0, period]

Postcondition

TGR register written with `duty_count`
 Change takes effect at next PWM period boundary (buffered by hardware)

Note

Not thread-safe: caller must ensure exclusive access to the TGR register

Duty count is not bounds-checked; caller must clamp before calling

```
volatile rx_mtu_channel_regs_t* mtu =
    (volatile rx_mtu_channel_regs_t*)internal_get_mtu_base(k_mtu_channel_0);
rx_err_t err = internal_set_duty_raw_mtu(mtu, k_mtu_output_b, 1500U);
```

8.129.3.10 rx`mtu`deinit()

```
rx_err_t rx_mtu_deinit (
    const rx_mtu_channel_t channel) [nodiscard]
```

Deinitialize an MTU PWM channel.

Deinitialize MTU channel.

Performs an orderly shutdown of the specified MTU channel:

1. Stop the timer counter ([rx_mtu_stop\(\)](#))
2. Disable all four outputs (A, B, C, D) via [rx_mtu_enable_output\(\)](#)
3. Clear the cached period to 0
4. Clear the initialized flag

After this call the channel may be safely re-initialized with different parameters via [rx_mtu_init_pwm\(\)](#).

Precondition

Motor or load driven by this channel must be stopped externally before call
channel must be a valid MTU channel (0-4, 6-7)

Postcondition

Timer stopped and outputs disabled
`s_mtu_initialized[channel] == false`
`s_mtu_period[channel] == k_mtu_period_zero`

Note

Not thread-safe: do not call while another task is accessing this channel
Idempotent with respect to re-initialization (can call init again after)

Warning

Ensure motor is at rest before calling to avoid abrupt stop

```
rx_err_t err = rx_mtu_deinit(k_mtu_channel_0);
```

See also

[rx_mtu_init_pwm\(\)](#) Re-initialize after deinit

Here is the call graph for this function:

8.129.3.11 rx_mtu_enable_output()

```

rx_err_t rx_mtu_enable_output (
    const rx_mtu_channel_t channel,
    rx_mtu_output_t output,
    const bool enable) [nodiscard]

```

Enable or disable a single MTU PWM output pin.

Enable or disable PWM output.

Controls whether the MTIOCA/B/C/D pin actively drives the PWM waveform or is held in its initial state (off). Modifies the TIORH or TIORL register nibble corresponding to the requested output without disturbing other outputs.

Output	Register	Nibble
A	TIORH	Low (bits 3:0)
B	TIORH	High (bits 7:4)
C	TIORL	Low (bits 3:0)
D	TIORL	High (bits 7:4)

Precondition

Channel must be initialized via [rx_mtu_init_pwm\(\)](#)
output must be a valid [rx_mtu_output_t](#) enum value

Postcondition

TIORH or TIORL nibble updated; timer continues running
Other outputs on the same channel are unchanged

Note

Not thread-safe: caller must prevent concurrent register access
Timer keeps running; only output pin drive changes

Warning

Outputs may remain HIGH when disabled, depending on last compare state

```
rx_mtu_enable_output(k_mtu_channel_0, k_mtu_output_a, false); // disable
```

Here is the caller graph for this function:

8.129.3.12 rx_mtu_get_duty()

```

rx_err_t rx_mtu_get_duty (
    const rx_mtu_channel_t channel,
    const rx_mtu_output_t output,
    float * duty_percent) [nodiscard]

```

Read the current PWM duty cycle as a floating-point percentage.

Get current duty cycle.

Reads the TGR register for the specified output and converts the raw count to a percentage using the cached period value.

$$\text{duty_percent} = \frac{\text{duty_count} \times 100}{\text{period}}$$

Precondition

Channel must be initialized via [rx_mtu_init_pwm\(\)](#)
duty_percent must point to valid float storage

Postcondition

*duty_percent contains duty cycle in [0.0, 100.0] on success
Hardware TGR register unchanged

Note

Not thread-safe: concurrent set_duty calls may cause torn reads

```
float duty;
rx_err_t err = rx_mtu_get_duty(k_mtu_channel_0, k_mtu_output_b, &duty);
```

8.129.3.13 rx_mtu_get_period()

```
rx_err_t rx_mtu_get_period (
    const rx_mtu_channel_t channel,
    uint16_t * period_count) [nodiscard]
```

Get PWM period count for MTU channel.

Get PWM period count.

Returns the cached period value (TGRA) from initialization. Useful for calculating raw duty counts from percentages without floating-point.

Precondition

Channel must be initialized via [rx_mtu_init_pwm\(\)](#)
 period_count must point to valid uint16_t storage

Postcondition

*period_count contains the TGRA register value on success
 Hardware registers unchanged

Note

Thread-safe: reads from static cache, no hardware access

```
uint16_t period;
rx_err_t err = rx_mtu_get_period(k_mtu_channel_0, &period);
if (err == k_rx_ok) {
    uint16_t half_duty = period / 2U; // 50%
    rx_mtu_set_duty_raw(k_mtu_channel_0, k_mtu_output_b, half_duty);
}
```

Here is the call graph for this function:

8.129.3.14 rx`mtu`init`pwm()

```
rx_err_t rx_mtu_init_pwm (
    const rx_mtu_channel_t channel,
    const rx_mtu_config_t * config) [nodiscard]
```

Initialize MTU channel for PWM operation.

Initialize MTU channel for PWM output.

Configures an MTU channel for PWM Mode 1 (triangle wave, center-aligned) operation. Performs complete hardware setup including module clock enable, timer configuration, and automatic start.

8.129.3.15 Initialization Sequence

1. Validate config pointer
2. Get channel register base address
3. Calculate period from frequency
4. Enable MTU module clock (clear MSTPA bit)
5. Stop timer if running
6. Configure TCR (clock source, clear condition)
7. Configure TMDR (PWM Mode 1)
8. Configure TIORH/TIORL (output behavior)
9. Set TGRA (period), clear TGRB/TGRC/TGRD (duty = 0)
10. Clear TCNT counter
11. Store period and set initialized flag
12. Start timer

8.129.3.16 PWM Mode 1 Configuration

Register	Value	Effect
TCR	TPSC=1, CCLR=TGRA	PCLKA/1, clear on TGRA match
TMDR	MD=PWM1	Triangle wave mode
TIORH/ L	Init low	Outputs toggle on compare match

Precondition

System clock configured (PCLKA = 120 MHz)
 config pointer valid with valid frequency

Postcondition

MTU channel configured and timer running
 All duty cycles initialized to 0%
 s_mtu_initialized[channel] = true

Note

Timer starts automatically
 Call once during system initialization

Warning

Not thread-safe: Configure before starting motor tasks

Example:

```
rx_mtu_config_t config = {
    .frequency_hz = 20000 // 20 kHz
};
rx_err_t err = rx_mtu_init_pwm(k_mtu_channel_0, &config);
```

Here is the call graph for this function:

8.129.3.17 rx_mtu_set_duty()

```
rx_err_t rx_mtu_set_duty (  
    const rx_mtu_channel_t channel,  
    rx_mtu_output_t output,  
    const float duty_percent) [nodiscard]
```

Set PWM duty cycle as a floating-point percentage.

Set PWM duty cycle.

Converts a percentage value to raw timer counts using the cached period and writes it to the appropriate TGR register. The update is buffered and takes effect at the next PWM period boundary (glitch-free).

Algorithm:

1. Validate channel and initialization state
2. Validate duty_percent in range [0.0, 100.0]
3. Retrieve cached period from s_mtu_period[channel]
4. Compute duty_count = (duty_percent * period) / 100
5. Write duty_count to TGR register via [internal_set_duty_raw_mtu\(\)](#)

Precondition

Channel must be initialized via [rx_mtu_init_pwm\(\)](#)
duty_percent must be in [0.0, 100.0]

Postcondition

TGR register updated with new duty count
Change takes effect at next PWM period boundary

Note

Not thread-safe: caller must prevent concurrent access

```
rx_err_t err = rx_mtu_set_duty(k_mtu_channel_0, k_mtu_output_b, 50.0f);
```

Here is the call graph for this function:

8.129.3.18 rx`mtu`set`duty`raw()

```

rx_err_t rx_mtu_set_duty_raw (
    const rx_mtu_channel_t channel,
    rx_mtu_output_t output,
    uint16_t duty_count) [nodiscard]

```

Set PWM duty cycle using a raw 16-bit timer count.

Set PWM duty cycle (raw count value).

Directly sets the compare register (TGR) for the specified output to duty_count timer ticks. Values larger than the channel period are clamped to the period value (100% duty). The update is buffered.

Use this function when the caller has already converted a duty percentage to counts (e.g. via [rx_mtu_get_period\(\)](#)) to avoid redundant floating-point multiplication.

Precondition

Channel must be initialized via [rx_mtu_init_pwm\(\)](#)

duty_count should be in [0, period]; values above period are clamped

Postcondition

TGR register written with (possibly clamped) duty_count

Change takes effect at next PWM period boundary

Note

Not thread-safe: caller must prevent concurrent access

```
uint16_t period;
rx_mtu_get_period(k_mtu_channel_0, &period);
rx_mtu_set_duty_raw(k_mtu_channel_0, k_mtu_output_b, period / 2U); // 50%
```

8.129.3.19 rx`mtu`start()

```
rx_err_t rx_mtu_start (  
    const rx_mtu_channel_t channel) [nodiscard]
```

Start MTU counter (begin PWM generation).

Start MTU timer.

Sets the Count Start (CSTn) bit in the appropriate TSTR register to begin counter operation. Channels 0-4 use TSTRA, channels 6-7 use TSTRB.

8.129.3.20 TSTR Bit Mapping

Channel	Register	Bit
MTU0	TSTRA	CST0
MTU1	TSTRA	CST1
MTU2	TSTRA	CST2
MTU3	TSTRA	CST3
MTU4	TSTRA	CST4
MTU6	TSTRB	CST6
MTU7	TSTRB	CST7

Precondition

Channel initialized via [rx_mtu_init_pwm\(\)](#)

Postcondition

Timer counting, PWM output active

Note

Timer automatically started during init

Idempotent: Safe to call when already running

8.129.3.21 rx`mtu`stop()

```
rx_err_t rx_mtu_stop (
    const rx_mtu_channel_t channel) [nodiscard]
```

Stop MTU counter (halt PWM generation).

Stop MTU timer.

Clears the Count Start (CSTn) bit in the appropriate TSTR register to halt counter operation. Counter value and output state are preserved.

Precondition

None (can be called on uninitialized channel)

Postcondition

Timer stopped, counter preserved

Output pins hold current state

Note

Does NOT check initialization flag (safe for use during init)

Idempotent: Safe to call when already stopped

Warning

Outputs may remain HIGH - disable outputs for safe state

Here is the caller graph for this function:

8.129.4 Variable Documentation

8.129.4.1 s'mtu'initialized

```
bool s_mtu_initialized[k_mtu_max_channels] = {false} [static]
```

Track which MTU channels have been initialized.

Boolean array indexed by MTU channel number (0-7). Elements are set to true by [rx_mtu_init_pwm\(\)](#) and cleared to false by [rx_mtu_deinit\(\)](#). Guards all public API functions that require prior initialization.

Note

Indexed directly by [rx_mtu_channel_t](#) value (sparse: indices 0-4, 6-7)

Warning

Do not modify directly - use the public API functions

Since

Version 1.0.0

Definition at line 195 of file [rx_mtu.c](#).

```
00195 {false};
```

Referenced by [rx_mtu_deinit\(\)](#), [rx_mtu_enable_output\(\)](#), [rx_mtu_get_duty\(\)](#), [rx_mtu_get_period\(\)](#), [rx_mtu_init_pwm\(\)](#), [rx_mtu_set_duty\(\)](#), [rx_mtu_set_duty_raw\(\)](#), and [rx_mtu_start\(\)](#).

8.129.4.2 s`mtu`period

```
uint16_t s_mtu_period[k_mtu_max_channels] = {} [static]
```

Cached PWM period register values for each MTU channel.

Stores the TGRA (period) register value written during [rx_mtu_init_pwm\(\)](#). Used by [rx_mtu_set_duty\(\)](#) to convert duty percentage to raw counts without re-reading the hardware register, and by [rx_mtu_get_period\(\)](#) to report the current period.

Note

Indexed directly by [rx_mtu_channel_t](#) value (sparse: indices 0-4, 6-7)

Warning

Do not modify directly - value must match hardware TGRA register

00001 /**
00002  * @file rx_mtu.c
00003  * @brief MTU PWM Driver Implementation for RX72N
00004  *
00005  * @details
00006  * **Production-grade implementation** of the Multi-Function Timer Unit (MTU)
00007  * peripheral driver for PWM generation on RX72N. The MTU provides 16-bit
00008  * timer resolution with multiple outputs per channel.
00009  *
00010  * ## Module Architecture
00011  *
00012  * The MTU peripheral is organized as:
00013  * - **MTU0-MTU4**: First group, controlled by MSTPCRA.MSTPA9 and TSTRA
00014  * - **MTU6-MTU7**: Second group, controlled by MSTPCRA.MSTPA9 and TSTRB
00015  * - **Note**: MTU5 exists but is excluded from general PWM use
00016  *
00017  * ## PWM Mode 1 (Triangle Wave - Center-Aligned)
00018  *
00019  * This driver configures MTU in PWM Mode 1 for center-aligned PWM:
00020  * - Counter counts up from 0 to TGRA (period), then down to 0
00021  * - Compare matches on TGRB/TGRC/TGRD control duty cycle
00022  * - Symmetric PWM pulses reduce harmonic content
00023  * - Lower EMI compared to edge-aligned PWM
00024  *
00025  * @par PWM Timing Diagram:
00026  *
00027  * ```
00028  *          TGRA (period)
00029  *          |
00030  *      /\  /\  /\
00031  *     /\  /\  /\
00032  *    /\  /\  /\
00033  *   /\  /\  /\
00034  *  /\  /\  /\
00035  * /\  /\  /\
00036  * 0-----0-----0-----0
00037  *   | | | | | | | |
00038  *   TGRB TGRB (compare match points)
00039  * ```
00040  *
00041  * ## Frequency and Resolution
00042  *
00043  * @par Calculation:
00044  * @f
00045  * \text{Period} = \frac{f_{PCLKA}}{2 \times f_{PWM}}
00046  * @f
00047  *
00048  * @par Example: 20kHz PWM with PCLKA=120MHz:
00049  *
00050  * | Parameter | Value | Notes |
00051  * |-----|-----|-----|
00052  * | Period | 3000 counts | 120MHz / (2 x 20kHz) |
00053  * | Resolution | ~11.5 bits | log2(3000) ~ 11.5 |
00054  * | Duty range | 0-3000 | 0-100% in integer counts |
00055  * | Step size | 0.033% | 100% / 3000 |
00056  *
00057  * ## Register Base Addresses
00058  *
00059  * | Channel | Base Address | TSTR Register |
00060  * |-----|-----|-----|
00061  * | MTU0 | 0x000C1300 | TSTRA (bit 0) |
00062  * | MTU1 | 0x000C1380 | TSTRA (bit 1) |
00063  * | MTU2 | 0x000C1400 | TSTRA (bit 2) |
00064  * | MTU3 | 0x000C1200 | TSTRA (bit 6) |
00065  * | MTU4 | 0x000C1201 | TSTRA (bit 7) |
00066  * | MTU6 | 0x000C1A00 | TSTRB (bit 6) |
00067  * | MTU7 | 0x000C1A01 | TSTRB (bit 7) |
00068  *
00069  * ## Static Variables
00070  *
00071  * | Variable | Type | Purpose |
00072  * |-----|-----|-----|
00073  * | s_mtu_initialized[] | bool[8] | Track which channels are initialized |
00074  * | s_mtu_period[] | uint16_t[8] | Cache period values for duty calculation |
00075  * | s_tag | const char* | Log tag "MTU" |
00076  *
00077  * @par NASA Power of 10 Compliance:
00078  *
00079  * | Rule | Status | Implementation |
00080  * |-----|-----|-----|
00081  * | 1. Simple control flow | [OK] | No goto/setjmp/recursion |
00082  * | 2. Fixed loop bounds | [OK] | No unbounded loops |
00083  * | 3. No dynamic allocation | [OK] | All static, zero malloc |
00084  * | 4. Small functions | [OK] | All functions < 60 lines |

```

```

00083 * | 5. Assertions | [OK] | RX_VALIDATE_PTR, RX_VALIDATE_INIT |
00084 * | 6. Narrow scope | [OK] | Static variables, internal functions |
00085 * | 7. Check return values | [OK] | All rx_err_t returns checked |
00086 * | 8. Limited preprocessor | [OK] | C23 typed enums for constants |
00087 * | 9. Pointer restrictions | [OK] | Single-level pointers |
00088 * | 10. Compiler warnings | [OK] | Clean with -Wall -Wextra -Werror |
00089 *
00090 * @par SOLID Principles:
00091 *
00092 * **Single Responsibility**: This file handles ONLY MTU PWM generation.
00093 * Motor control logic and encoder reading are in separate modules.
00094 *

Enumerations

- enum `poeg_icu_constants_t` : `uint8_t` { `k_icu_ir_clear` = 0 , `k_ier_bit_enable_base` = 1 , `k_ier_bits_per_reg` = 8 }
ICU configuration constants for POEG interrupts.
- enum `poeg_init_config_t` : `uint32_t` { `k_poeg_init_value` }
POEG initialization configuration values.
- enum `poeg_gtintad_values_t` : `uint32_t` { `k_gtintad_motor_0` = (`k_gptw_gtintad_grp_a` | `k_gptw_gtintad_grpdte` | `k_gptw_gtintad_grpabl`) , `k_gtintad_motor_1` = (`k_gptw_gtintad_grp_b` | `k_gptw_gtintad_grpdte` | `k_gptw_gtintad_grpabl`) , `k_gtintad_motor_2` = (`k_gptw_gtintad_grp_c` | `k_gptw_gtintad_grpdte` | `k_gptw_gtintad_grpabl`) , `k_gtintad_motor_3` = (`k_gptw_gtintad_grp_d` | `k_gptw_gtintad_grpdte` | `k_gptw_gtintad_grpabl`) }
Pre-computed GTINTAD values for each GPTW-POEG link.

Functions

- static volatile `uint32_t` * `poeg_grpbl2_reg` (void)
Accessors for the GROUPBL2 status/enable registers.
- static volatile `uint32_t` * `poeg_genbl2_reg` (void)
- static void `internal_enable_poeg_groupbl2_irq` (`uint8_t` priority)
Configure ICU for the shared POEG GROUPBL2 vector.
- static void `internal_configure_gtintad` (`uint8_t` motor_index)
Configure GPTW GTINTAD for POEG group linkage.

- void [poeg_groupbl2_isr](#) (void)
GROUPBL2 ISR - dispatches POEGGA/B/C/D fault interrupts.
- rx_err_t [rx_poeg_init](#) (void)
Initialize POEG fault protection for all 4 motor channels.
- rx_err_t [rx_poeg_get_fault_status](#) (uint8_t motor_index, bool *fault_active)
Read latched POEG fault status (implementation).
- rx_err_t [rx_poeg_clear_fault](#) (uint8_t motor_index)
Acknowledge and clear all latched POEG fault flags (implementation).
- rx_err_t [rx_poeg_software_stop](#) (uint8_t motor_index)
Trigger a Software Stop (implementation).
- rx_err_t [rx_poeg_clear_software_stop](#) (uint8_t motor_index)
Release a Software Stop (implementation).

Variables

- static const char *const [s_tag](#) = "POEG"
Module log tag.
- static volatile [rx_poegg_regs_t](#) *const [s_poeg_groups](#) [[k_poeg_motor_count](#)]
POEG group register accessor lookup table (indexed by motor).
- static volatile [rx_gptw_channel_regs_t](#) *const [s_gptw_channels](#) [[k_poeg_motor_count](#)]
GPTW channel register accessor lookup table (indexed by motor).
- static const uint32_t [s_gtintad_values](#) [[k_poeg_motor_count](#)]
GTINTAD values lookup table (indexed by motor).
- static const uint8_t [s_poeg_grpbl2_bits](#) [[k_poeg_motor_count](#)]
GRPBL2 sub-source bit for each POEG group (indexed by motor).

8.131.1 Detailed Description

POEG Motor Fault Protection Driver Implementation.

Implements hardware-level emergency PWM output disable for the STAR motor controller. Each of the 4 DRV8263H motor drivers has its nFAULT output connected to a GTETRG pin, which feeds a POEG group. When a fault is detected, POEG immediately disables GPTW PWM output (Hi-Z).

POEGGA/B/C/D are sub-sources of the shared GROUPBL2 vector (107) on RX72N (HW manual R01↔UH0824EJ0111 Section 15.3, Table 15.4). A single GROUPBL2 ISR reads GRPBL2, dispatches to each faulted group, and:

1. Clears the ICU GROUPBL2 IR flag
2. Logs which POEG groups asserted
3. Triggers e-stop via shared_data

Implementation Notes

- POEG PIDE (pin detection enable) is write-once after reset
- nFAULT is active-low, so INV bit is set to detect low-level
- Noise filter enabled with PCLKB/8 sampling (~400ns at 60MHz)
- GTINTAD links each GPTW channel to its corresponding POEG group

8.131.2 Enumeration Type Documentation

8.131.2.1 poeg`gtintad`values`t

enum [poeg_gtintad_values_t](#) : uint32_t

Pre-computed GTINTAD values for each GPTW-POEG link.

Each GPTW channel's GTINTAD register is configured to:

- Select the corresponding POEG group (A/B/C/D)
- Enable dead-time error detection (GRPDTE)
- Enable simultaneous low output detection (GRPABL)

Since

Version 1.0.0

8.131.3.4 poeg`groupbl2`isr()

```
void poeg_groupbl2_isr (  
    void )
```

GROUPBL2 ISR - dispatches POEGGA/B/C/D fault interrupts.

Handles the shared GROUPBL2 vector (107). Reads GRPBL2 to identify which POEG sub-sources asserted, logs each, and triggers a single e-stop.

Precondition

POEG groups initialized via [rx_poeg_init\(\)](#)

Postcondition

For every POEGG bit set in GRPBL2, the fault is logged
Global e-stop triggered once if any POEG source fired

Note

Thread Safety: ISR context, runs at priority 14

Since

Version 1.0.0

Definition at line 226 of file [rx_poeg.c](#).

8.131.3.6 rx`poeg`clear`fault()

```
rx_err_t rx_poeg_clear_fault (
    uint8_t motor_index)
```

Acknowledge and clear all latched POEG fault flags (implementation).

Clear POEG fault and re-enable motor output.

Reads POEGGn, masks off the PIDF / IOCF / OSTPF latched-fault bits, and writes the result back. Refuses to clear (returns k_rx_err_busy) while the underlying nFAULT pin is still active (POEGGn.ST==0 indicates nFAULT still asserted under INV=1). After a successful clear, also clears any driver-fault E-Stop in shared_data when applicable, so the system can resume motor control if the underlying physical fault has been cleared.

Note

Not thread-safe with concurrent access to shared_data E-Stop fields. Typically called from the safety supervisor task.

Definition at line 327 of file rx_poeg.c.

```
00328 {
00329     if (motor_index >= k_poeg_motor_count) {

8.131.3.7 rx`poeg`clear`software`stop()

```
rx_err_t rx_poeg_clear_software_stop (
    uint8_t motor_index)
```

Release a Software Stop (implementation).

Release software emergency stop on a specific motor.

Reads POEGGn, clears the SSF bit, and writes the result back. This re-enables the GPTW outputs of the targeted motor (subject to any hardware-latched fault flags still being cleared first).

Note

Safe from any context including ISR; single read-modify-write.

Definition at line 388 of file [rx_poeg.c](#).

```
00389 {
00390     if (motor_index >= k_poeg_motor_count) {
00391         return k_rx_err_invalid_arg;

00397     return k_rx_ok;
00398 }
```

References [k_poeg_motor_count](#), [k_poeg_ssf_stop](#), and [s_poeg_groups](#).

8.131.3.8 rx_poeg_get_fault_status()

```
rx_err_t rx_poeg_get_fault_status (
    uint8_t motor_index,
    bool * fault_active)
```

Read latched POEG fault status (implementation).

Check if a motor has an active POEG fault.

Reads POEGGn for the specified motor's POEG group and checks the OR of the three fault-source bits: PIDF (port input fault), IOCF (output comparator fault), and OSTPF (over-stop signal fault). Reports whether any of them are currently latched.

Note

Safe from any context including ISR; single register read.

Definition at line 297 of file [rx_poeg.c](#).

```
00298 {
00299     RX_CHECK_NULL_PTR(fault_active, s_tag, "fault_active is nullptr");

8.131.3.9 rx`poeg`init()

```
rx_err_t rx_poeg_init (
    void )
```

Initialize POEG fault protection for all 4 motor channels.

Configures POEG Groups A-D for hardware motor fault protection:

1. Enables external pin detection (PIDE) on each group
2. Enables noise filter (NFEN) with PCLKB/8 sampling ($\sim 400\text{ns}$)
3. Inverts input (INV) since DRV8263H nFAULT is active-low
4. Links each GPTW channel to its POEG group via GTINTAD
5. Configures ICU interrupts for vectors 188-191 at priority 14

After initialization, a DRV8263H fault will:

- Immediately disable GPTW PWM output (hardware, $\sim \text{nanoseconds}$)
- Fire POEG ISR which sets fault flags in shared_data

Returns

rx_err_t Error code

Return values

k_rx_ok	All 4 POEG groups initialized successfully
k_rx_err_hw_init_failed	POEG register write verification failed

Precondition

GPTW module enabled (MSTPCRA.MSTPA7 = 0)

GTETRGR pins configured via MPC: PDR=0 (input), PSEL=0x1E (GTETRGR function select)

shared_data initialized

Postcondition

POEG Groups A-D enabled with pin detection + noise filter

GPTW0-3 GTINTAD linked to POEG Groups A-D respectively

ICU vectors 188-191 enabled at priority 14

Any existing nFAULT assertion will trigger immediately

Note

Thread Safety: Call once during hardware_init, before motor tasks start

Warning

PIDE enable bit is write-once after reset – cannot be disabled

NASA Power of 10 Compliance:

- Rule 1: No goto, setjmp, recursion
- Rule 2: Loop bounded by k_poeg_motor_count (4)
- Rule 3: No dynamic allocation
- Rule 5: 3 preconditions, 4 postconditions
- Rule 7: Return value checked
- Rule 8: All constants as C23 typed enums

8.131.3.10 rx`poeg`software`stop()

```
rx_err_t rx_poeg_software_stop (
    uint8_t motor_index)
```

Trigger a Software Stop (implementation).

Trigger software emergency stop on a specific motor.

Sets POEGn.SSF=1, force-disabling the GPTW outputs of the targeted motor as if a hardware fault had occurred. Does not touch the latched fault flags; once a Software Stop is set, the user must call [rx_poeg_clear_software_stop\(\)](#) to release.

Note

Safe from any context including ISR; single register write. Used by the safety supervisor for software-initiated E-Stop.

Definition at line 368 of file [rx_poeg.c](#).

```
00369 {
00370     if (motor_index >= k_poeg_motor_count) {

00001 /**
00002  * @file rx_poeg.c
00003  * @brief POEG Motor Fault Protection Driver Implementation
00004  *
00005  * @details
00006  * Implements hardware-level emergency PWM output disable for the STAR
00007  * motor controller. Each of the 4 DRV8263H motor drivers has its nFAULT
00008  * output connected to a GTETRG pin, which feeds a POEG group. When a
00009  * fault is detected, POEG immediately disables GPTW PWM output (Hi-Z).
00010  *
00011  * POEGGA/B/C/D are sub-sources of the shared GROUPBL2 vector (107) on
00012  * RX72N (HW manual R01UH0824EJ0111 Section 15.3, Table 15.4). A single
00013  * GROUPBL2 ISR reads GRPBL2, dispatches to each faulted group, and:
00014  * 1. Clears the ICU GROUPBL2 IR flag
00015  * 2. Logs which POEG groups asserted
00016  * 3. Triggers e-stop via shared_data
00017  *
00018  * @par Implementation Notes
00019  * - POEG PIDE (pin detection enable) is write-once after reset
00020  * - nFAULT is active-low, so INV bit is set to detect low-level
00021  * - Noise filter enabled with PCLKB/8 sampling (~400ns at 60MHz)
00022  * - GTINTAD links each GPTW channel to its corresponding POEG group
00023  *

Enumerations

- enum `tmr_period_limits_t` : `uint32_t` { `k_tmr_us_per_sec` = 1000000U , `k_tmr_max_tcora` = 0xFFU , `k_tmr_max_tcora_16bit` = 0xFFFFU }
Compile-time period / divisor limits.
- enum `tmr_channel_count_t` : `uint8_t` { `k_tmr_channel_count_internal` = 4 }
Array sizing constant for per-channel state.
- enum `tmr_pclk_divisor_t` : `uint32_t` {
 `k_tmr_pclk_div_1` = 1U , `k_tmr_pclk_div_2` = 2U , `k_tmr_pclk_div_8` = 8U ,
 `k_tmr_pclk_div_32` = 32U ,
 `k_tmr_pclk_div_64` = 64U , `k_tmr_pclk_div_1024` = 1024U , `k_tmr_pclk_div_8192` = 8192U
 , `k_tmr_pclk_div_none` = 0U }
Integer prescaler ratios for internal clock sources.
- enum `tmr_byte_shift_t` : `uint8_t` { `k_tmr_byte_shift` = 8U , `k_tmr_byte_mask` = 0xFFU }
Shift / mask constants for packing cascaded 16-bit counts.

Functions

- `RX_STATIC_TESTABLE volatile rx_tmr_channel_regs_t * internal_tmr_get_regs(rx_tmr_channel_t channel)`
Get register pointer for a TMR channel.
- static `uint32_t internal_tmr_unit_mstp_bit(rx_tmr_channel_t channel)`
Return the MSTPCRA bit mask for a TMR channel's unit.
- static void `internal_tmr_enable_module_clock(rx_tmr_channel_t channel)`
Enable the module clock for the channel's TMR unit.
- static `rx_err_t internal_tmr_clock_bits(rx_tmr_clock_source_t source, uint8_t *bits)`
Map a clock source to TCCR CSS|CKS bits.
- static `uint32_t internal_tmr_clock_divider(rx_tmr_clock_source_t source)`
Return the integer divider for an internal clock source.
- static `uint8_t internal_tmr_compose_tcr(const rx_tmr_config_t *config)`
Compose TCR value from config.
- static `uint8_t internal_tmr_compose_tcsr(const rx_tmr_config_t *config)`
Compose TCSR value from config (OSA/OSB fields).
- static `rx_err_t internal_tmr_validate_config(const rx_tmr_config_t *config)`

- Validate enum fields of a configuration.
- static void `internal_tmr_program_channel` (`rx_tmr_channel_t` channel, const `rx_tmr_config_t` *config)
 - Write register fields for a single channel during init.
- static void `internal_tmr_init_cascade_pair` (const `rx_tmr_config_t` *config)
 - Program the paired odd channel in a 16-bit cascade configuration.
- `rx_err_t rx_tmr_init` (const `rx_tmr_config_t` *config)
 - Initialise a TMR channel (or cascaded pair).
- `rx_err_t rx_tmr_start` (`rx_tmr_channel_t` channel)
 - Start counting on a TMR channel.
- `rx_err_t rx_tmr_stop` (`rx_tmr_channel_t` channel)
 - Stop a TMR channel counter.
- `rx_err_t rx_tmr_read` (`rx_tmr_channel_t` channel, `uint16_t` *value)
 - Read the current TMR counter value.
- `rx_err_t rx_tmr_set_period_us` (`rx_tmr_channel_t` channel, `uint32_t` period_us)
 - Set the compare-match period in microseconds.
- `rx_err_t rx_tmr_register_compare_match_isr` (`rx_tmr_channel_t` channel, `rx_tmr_isr_callback_t` callback)
 - Register an interrupt callback for compare-match / overflow events.
- `rx_err_t rx_tmr_deinit` (`rx_tmr_channel_t` channel)
 - Deinitialise a TMR channel.
- void `rx_tmr_isr_dispatch` (`rx_tmr_channel_t` channel)
 - Internal dispatcher invoked by the SELECTB vector shim.

Variables

- static const char *const `s_tag` = "TMR"
 - Logging tag for the TMR module.
- static bool `s_tmr_initialized` [`k_tmr_channel_count_internal`] = {false, false, false, false}
 - Per-channel init flags indexed by `rx_tmr_channel_t`.
- static `rx_tmr_mode_t` `s_tmr_mode` [`k_tmr_channel_count_internal`]
 - Per-channel operating mode (independent vs cascade).
- static `uint8_t` `s_tmr_clock_bits` [`k_tmr_channel_count_internal`] = {0U, 0U, 0U, 0U}
 - Cached TCCR clock bits (CSS|CKS) applied at `rx_tmr_start()`.
- static `rx_tmr_clock_source_t` `s_tmr_clock_source` [`k_tmr_channel_count_internal`]
 - Cached clock-source enum per channel (needed by `set_period_us`).
- static `rx_tmr_isr_callback_t` `s_tmr_callback` [`k_tmr_channel_count_internal`]
 - Per-channel compare-match / overflow callback pointers.

8.133.1 Detailed Description

TMR HAL Driver Implementation (8-bit + 16-bit cascade).

Implementation of the TMR hardware abstraction layer for the RX72N 8-bit Timer peripheral. Provides per-channel init/start/stop, counter readout, microsecond period programming, and SELECTB ISR-callback registration.

8.133.1.1 Initialisation Sequence

```
* rx_tmr_init(&config)
* |
* +-- 1. Validate config pointer (NASA Rule 5)
* +-- 2. Validate channel / clock / clear / outputs
* +-- 3. In cascade mode, require even channel
* +-- 4. Check not already initialised
* +-- 5. Enable unit module clock (MSTPA5 or MSTPA4, PRCR-gated)
* +-- 6. Stop counter (TCCR = 0)
* +-- 7. Program TCR (interrupt enables + CCLR)
* +-- 8. Program TCSR (output select A/B)
* +-- 9. Preload TCCR clock bits into internal state (start writes them)
* +-- 10. Clear TCNT to 0
* +-- 11. Mark channel initialised
* +-- 12. In cascade mode, also configure paired odd channel
*
```

8.133.1.2 Channel Register Access

Because even and odd TMR channels share a 16-byte block at different parity byte offsets, the driver uses [rx72n_tmr_regs.h](#) inline accessors ([tmr0\(\)..tmr3\(\)](#)) that each return a volatile pointer landing on the correct byte. Each struct field then accesses only the target channel's own byte.

NASA Power of 10 Compliance

- Rule 1: No goto / recursion / setjmp
- Rule 2: All loops bounded
- Rule 3: No dynamic memory
- Rule 4: Functions kept short (decomposed helpers)
- Rule 5: ≥ 2 validation checks per public function
- Rule 6: Variables at smallest scope
- Rule 7: All return values checked / explicitly cast (void)
- Rule 8: C23 typed enums for constants
- Rule 9: Function pointer permitted for ISR DIP
- Rule 10: -Wall -Wextra -Werror clean

enum [tmr_byte_shift_t](#) : uint8_t

Shift / mask constants for packing cascaded 16-bit counts.

Since

Version 1.0.0

Enumerator

k_tmr_byte_shift	Shift to move high byte to bits [15:8]
k_tmr_byte_mask	Mask for isolating one byte

Definition at line [138](#) of file [rx_tmr.c](#).

```
00138         : uint8_t {
00139   k_tmr_byte_shift = 8U,    /**< Shift to move high byte to bits [15:8] */
00140   k_tmr_byte_mask  = 0xFFU, /**< Mask for isolating one byte */
00141 } tmr_byte_shift_t;
```

8.133.2.2 tmr`channel`count`

enum [tmr_channel_count_t](#) : uint8_t

Array sizing constant for per-channel state.

Since

Version 1.0.0

Enumerator

k_tmr_channel_count_internal	TMR0..TMR3
------------------------------	------------

Definition at line [108](#) of file [rx_tmr.c](#).

```
00108         : uint8_t {
00109   k_tmr_channel_count_internal = 4, /**< TMR0..TMR3 */
00110 } tmr_channel_count_t;
```

8.133.2.3 tmr_pclk_divisor_t

```
enum tmr_pclk_divisor_t : uint32_t
```

Integer prescaler ratios for internal clock sources.

The RX72N TMR peripheral divides PCLKB by one of these ratios before feeding the counter. Each value mirrors a `k_tmr_clock_pclk_div_*` enum value and is used by `internal_tmr_clock_divider()` to compute the effective tick rate. Named constants avoid magic-number literals.

Since

Version 1.0.0

Enumerator

<code>k_tmr_pclk_div_1</code>	Prescaler /1
<code>k_tmr_pclk_div_2</code>	Prescaler /2
<code>k_tmr_pclk_div_8</code>	Prescaler /8
<code>k_tmr_pclk_div_32</code>	Prescaler /32
<code>k_tmr_pclk_div_64</code>	Prescaler /64
<code>k_tmr_pclk_div_1024</code>	Prescaler /1024
<code>k_tmr_pclk_div_8192</code>	Prescaler /8192
<code>k_tmr_pclk_div_none</code>	Sentinel: external clock (no PCLK divider)

Definition at line 122 of file `rx_tmr.c`.

8.133.3.11 rx_tmr_deinit()

```

rx_err_t rx_tmr_deinit (
    rx_tmr_channel_t channel) [nodiscard]

```

Deinitialise a TMR channel.

Stops the counter, clears TCR/TCSR/TCCR, zeroes TCNT, removes any installed ISR callback, and marks the channel as uninitialised. The module stop bit is NOT asserted because the paired channel in the same unit may still be active.

Parameters

in	channel	TMR channel (cascade: pass the even channel)
----	---------	--

Returns

rx_err_t Error code

Return values

k_rx_ok	Channel released
k_rx_err_invalid_arg	Channel out of range

Precondition

(none - safe to call on uninitialised channel)

Postcondition

Channel registers cleared
Internal init flag cleared

Note

Thread Safety: Not thread-safe.

Since

Version 1.0.0

Definition at line 625 of file [rx_tmr.c](#).

```

8.133.3.12 rx_tmr_init()

```
rx_err_t rx_tmr_init (
    const rx_tmr_config_t * config) [nodiscard]
```

Initialise a TMR channel (or cascaded pair).

Enables the module stop clock for the channel's unit (MSTPA5 for unit 0, MSTPA4 for unit 1), stops the counter, writes TCR/TCSR/TCCR/TCORA/ TCORB according to the supplied configuration, and clears TCNT to zero. In cascade mode, both channels of the unit are configured in one call.

Parameters

in	config	Pointer to configuration (non-NULL)
----	--------	-------------------------------------

Returns

rx_err_t Error code

Return values

k_rx_ok	Success
k_rx_err_null_ptr	config is NULL
k_rx_err_invalid_arg	Invalid channel, clock, clear, output, or a cascade request on an odd channel
k_rx_err_invalid_state	Channel already initialised

Precondition

System clocks configured (PCLKB running)

In cascade mode, config->channel is k_tmr_channel_0 or k_tmr_channel_2 (even channel)

Postcondition

Channel counter stopped at 0

Module clock enabled (MSTPCRA bit cleared)

Internal init flag set

Note

Not thread-safe; call from main-task context at startup.

Here is the call graph for this function:

8.133.3.13 rx_tmr_isr_dispatch()

```
void rx_tmr_isr_dispatch (
    rx_tmr_channel_t channel)
```

Internal dispatcher invoked by the SELECTB vector shim.

Called from the low-level vector when a TMR CMIA/CMIB/OVI interrupt fires. Clears the source flag in the TMR (compare-match sets no persistent status bit, so the hardware does it automatically; this function exists so the test harness can synthesise ISR invocations) and invokes the registered user callback.

8.133.3.14 rx_tmr_read()

```
rx_err_t rx_tmr_read (
    rx_tmr_channel_t channel,
    uint16_t * value) [nodiscard]
```

Read the current TMR counter value.

For 8-bit mode, *value holds the 8-bit TCNT zero-extended to uint16_t. For 16-bit cascade mode, *value holds the full 16-bit value (even channel = upper byte, odd channel = lower byte).

Parameters

in	channel	TMR channel (cascade: pass the even channel)
out	value	Pointer receiving counter value (non-NULL)

Returns

rx_err_t Error code

Return values

k_rx_ok	Success
k_rx_err_null_ptr	value is NULL
k_rx_err_invalid_arg	Channel out of range

k_rx_err_invalid_state	Channel not initialised
------------------------	-------------------------

Precondition

Channel initialised

Postcondition

*value contains counter at time of read

Note

Thread Safety: Safe - single volatile read.

Here is the call graph for this function:

8.133.3.15 `rx_tmr_register_compare_match_isr()`

```
rx_err_t rx_tmr_register_compare_match_isr (
    rx_tmr_channel_t channel,
    rx_tmr_isr_callback_t callback) [nodiscard]
```

Register an interrupt callback for compare-match / overflow events.

Installs a user callback invoked from the ICU SELECTB dispatcher when any of the channel's enabled TMR interrupts (CMIA, CMIB, or OVI) fire. The driver's ISR shim clears the source flag before calling back. Pass NULL to deregister.

Parameters

in	channel	TMR channel (cascade: pass the even channel)
in	callback	User callback, or NULL to deregister

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	Success
<code>k_rx_err_invalid_arg</code>	Channel out of range

Precondition

Channel initialised with desired `irq_mask`

Postcondition

callback is installed (or cleared) atomically

Note

Thread Safety: Safe - function-pointer write is atomic on RX.

Since

Version 1.0.0

Definition at line 616 of file [rx_tmr.c](#).

```
00617 {
00618     if ((uint8_t)channel >= k_tmr_channel_count_internal) {
00619         return k_rx_err_invalid_arg;
00620     }
00621     s_tmr_callback[(uint8_t)channel] = callback;
00622     return k_rx_ok;
00623 }
```

References [k_tmr_channel_count_internal](#), and [s_tmr_callback](#).

8.133.3.16 rx`tmr`set`period`us()

```
rx_err_t rx_tmr_set_period_us (
    rx_tmr_channel_t channel,
    uint32_t period_us) [nodiscard]
```

Set the compare-match period in microseconds.

Recomputes and writes TCORA so that a TCORA compare match fires every period_us microseconds using the channel's configured clock source. TCORB is untouched. The caller must ensure the period fits into the channel counter width (8-bit single channel max = ~35 ms at PCLK/8192; 16-bit cascade max ~ = 8.9 s at PCLK/8192).

The underlying formula is $tcora = \text{round}(\text{period_us} * \text{PCLK_Hz} / (\text{divider} * 1e6)) - 1$, where divider is 1/2/8/32/64/1024/8192 according to the configured clock_source. External clock sources are not supported.

Parameters

in	channel	TMR channel (cascade: pass the even channel)
in	period_us	Desired period in microseconds (1..max for mode)

Returns

rx_err_t Error code

Return values

k_rx_ok	Success, TCORA updated
k_rx_err_invalid_arg	Channel out of range, period=0, period too large for the selected divider, or external clock source
k_rx_err_invalid_state	Channel not initialised

Precondition

Channel initialised with an internal-clock clock_source

Postcondition

TCORA holds the rounded tick count - 1

Note

Thread Safety: Safe - single register write.

Since

Version 1.0.0

8.133.3.17 rx`tmr`start()

```
rx_err_t rx_tmr_start (
    rx_tmr_channel_t channel) [nodiscard]
```

Start counting on a TMR channel.

Writes the configured clock-source bits into TCCR so the counter begins advancing on each selected clock edge. Channel must have been initialised via `rx_tmr_init()`.

Parameters

in	channel	TMR channel (cascade: pass the even channel)
----	---------	--

Returns

rx_err_t Error code

Return values

k_rx_ok	Counter started
k_rx_err_invalid_arg	Channel out of range
k_rx_err_invalid_state	Channel not initialised

Precondition

Channel initialised via `rx_tmr_init()`

Postcondition

TCCR programmed with clock source (counter running)

Note

Thread Safety: Safe - single register write.

8.133.3.18 rx_tmr_stop()

```

rx_err_t rx_tmr_stop (
    rx_tmr_channel_t channel) [nodiscard]

```

Stop a TMR channel counter.

Writes 0 into TCCR CKS/CSS to disable the clock input. The TCNT value is preserved.

Parameters

in	channel	TMR channel (cascade: pass the even channel)
----	---------	--

Returns

rx_err_t Error code

Return values

k_rx_ok	Counter stopped
k_rx_err_invalid_arg	Channel out of range
k_rx_err_invalid_state	Channel not initialised

Precondition

Channel initialised

Postcondition

Counter no longer advances

TCNT preserved

Here is the call graph for this function:

8.133.4 Variable Documentation

8.133.4.1 s`tag

```
const char* const s_tag = "TMR" [static]
```

Logging tag for the TMR module.

4 bytes in .rodata.

Since

Version 1.0.0

Definition at line 86 of file [rx_tmr.c](#).

8.133.4.2 s`tmr`callback

```
rx_tmr_isr_callback_t s_tmr_callback[k_tmr_channel_count_internal] [static]
```

Initial value:

```

                                = {
    NULL,
    NULL,
    NULL,
    NULL,
}

```

Per-channel compare-match / overflow callback pointers.

Since

Version 1.0.0

Definition at line 199 of file [rx_tmr.c](#).

```

00199
00200 NULL,
00201 NULL,
00202 NULL,
00203 NULL,
00204 };
                                {

```

Referenced by [rx_tmr_deinit\(\)](#), [rx_tmr_isr_dispatch\(\)](#), and [rx_tmr_register_compare_match_isr\(\)](#).

8.133.4.3 s`tmr`clock`bits

```
uint8_t s_tmr_clock_bits[k_tmr_channel_count_internal] = {0U, 0U, 0U, 0U} [static]
```

Cached TCCR clock bits (CSS|CKS) applied at [rx_tmr_start\(\)](#).

[rx_tmr_init\(\)](#) computes the TCCR clock-field value but does NOT write it immediately because that would start the counter. [rx_tmr_start\(\)](#) OR's these bits into TCCR when requested. [rx_tmr_stop\(\)](#) clears the clock field so the counter halts.

Since

Version 1.0.0

Definition at line 180 of file [rx_tmr.c](#).

```
00180 {0U, 0U, 0U, 0U};
```

Referenced by [internal_tmr_init_cascade_pair\(\)](#), [rx_tmr_deinit\(\)](#), [rx_tmr_init\(\)](#), and [rx_tmr_start\(\)](#).

8.133.4.4 s'tmr'clock'source

[rx_tmr_clock_source_t](#) [s_tmr_clock_source\[k_tmr_channel_count_internal\]](#) [static]

Initial value:

```

                                = {
    k_tmr_clock_pclk_div_1,
    k_tmr_clock_pclk_div_1,
    k_tmr_clock_pclk_div_1,
    k_tmr_clock_pclk_div_1,
}

```

Cached clock-source enum per channel (needed by [set_period_us](#)).

Since

Version 1.0.0

Definition at line [187](#) of file [rx_tmr.c](#).

```

00187
00188 k_tmr_clock_pclk_div_1,
00189 k_tmr_clock_pclk_div_1,
00190 k_tmr_clock_pclk_div_1,

```

Enumerations

- enum [tpu_phase_channel_count_t](#) : uint8_t { [k_tpu_phase_channel_count](#) = 4 }
- Number of phase-counting-capable TPU channels.

- enum `tpu_channel_index_t` : `uint8_t` { `k_tpu_idx_ch1` = 0 , `k_tpu_idx_ch2` = 1 , `k_tpu_idx_ch4` = 2 , `k_tpu_idx_ch5` = 3 }
Array index mapping for phase-counting channels.
- enum `tpu_tmdr_reset_t` : `uint8_t` { `k_tpu_tmdr_reset` = 0x00 }
TMDR register reset value (normal mode).
- enum `tpu_tcr_phase_count_t` : `uint8_t` { `k_tpu_tcr_phase_count` = 0x00 }
TCR register value for phase counting mode.
- enum `tpu_tier_disable_t` : `uint8_t` { `k_tpu_tier_all_disabled` = 0x40 }
TIER register value with all interrupts disabled.
- enum `tpu_tcmt_zero_t` : `uint16_t` { `k_tpu_tcmt_zero` = 0x0000 }
TCNT register zero value.

Functions

- static `rx_err_t` `internal_channel_to_index` (const `rx_tpu_channel_t` channel, `uint8_t` *index)
Map TPU channel number to array index.
- `RX_STATIC_TESTABLE` volatile `rx_tpu_regs_t` * `internal_get_regs` (const `rx_tpu_channel_t` channel)
Get register pointer for a phase-counting TPU channel.
- `RX_STATIC_TESTABLE` `uint8_t` `internal_get_cst_bit` (const `rx_tpu_channel_t` channel)
Get TSTR CST bit mask for a TPU channel.
- static `uint8_t` `internal_get_tmdr_mode` (const `rx_tpu_phase_mode_t` mode)
Map `rx_tpu_phase_mode_t` to TMDR.MD register value.
- static void `internal_enable_tpu_module_clock` (void)
Enable TPU module clock by clearing MSTPCRA.MSTPA13.
- `rx_err_t` `rx_tpu_init_phase_count` (const `rx_tpu_config_t` *config)
Initialize TPU channel for phase counting mode.
- `rx_err_t` `rx_tpu_start` (const `rx_tpu_channel_t` channel)
Start the TPU channel counter (begin phase counting).
- `rx_err_t` `rx_tpu_stop` (const `rx_tpu_channel_t` channel)
Stop the TPU channel counter (halt phase counting).
- `rx_err_t` `rx_tpu_read_count` (const `rx_tpu_channel_t` channel, `uint16_t` *count)
Read the current 16-bit encoder counter value.
- `rx_err_t` `rx_tpu_read_direction` (const `rx_tpu_channel_t` channel, bool *counting_up)
Read the current encoder counting direction.
- `rx_err_t` `rx_tpu_reset_count` (const `rx_tpu_channel_t` channel)
Reset the TPU channel encoder counter to zero.
- `rx_err_t` `rx_tpu_deinit` (const `rx_tpu_channel_t` channel)
Deinitialize a TPU phase-counting channel.

Variables

- static const char *const `s_tag` = "TPU"
Logging tag for TPU module.
- static bool `s_tpu_initialized` [`k_tpu_phase_channel_count`] = {false, false, false, false}
Track which phase-counting channels are initialized.

8.135.1 Detailed Description

TPU HAL Driver Implementation for Phase Counting Mode.

Implementation of the TPU hardware abstraction layer for RX72N quadrature encoder phase counting. This driver configures TPU channels 1, 2, 4, and 5 for hardware-based encoder position tracking with 4x resolution.

8.135.1.1 Module Architecture

The implementation is structured in three layers:

1. Constants & State: Typed enums for all magic numbers, static tracking
2. Internal Helpers: Channel validation, register access, bit mapping
3. Public API: User-facing functions documented in [rx_tpu.h](#)

8.135.1.2 Initialization Sequence

```
* rx_tpu_init_phase_count(&config)
* |
* +-- 1. Validate config (NULL, channel, phase_mode)
* +-- 2. Check not already initialized
* +-- 3. Enable TPU module clock (MSTPCRA.MSTPA13 = 0)
* +-- 4. Stop channel counter (TSTR.CSTn = 0)
* +-- 5. Set phase counting mode (TMDR.MD = mode)
* +-- 6. Set TCR to free-running (CCLR = disabled)
* +-- 7. Clear TCNT to zero
* +-- 8. Disable interrupts (TIER = 0x40; bit 6 reserved/must-write-1)
* +-- 9. Mark channel as initialized
*
```

8.135.1.3 Static Variables

Variable	Type	Purpose
s_tpu_initialized[]	bool[4]	Track which channels are initialized
s_tag	const char*	Log tag "TPU"

8.135.1.4 Channel-to-Index Mapping

Phase counting channels (1, 2, 4, 5) are mapped to array indices 0-3:

Channel	Index	Use in STAR	Clock Pins
TPU1	0	Back-right encoder	TCLKA + TCLKB
TPU2	1	Back-left encoder	TCLKC + TCLKD
TPU4	2	Available	TCLKC + TCLKD

Channel	Index	Use in STAR	Clock Pins
TPU5	3	Available	TCLKA + TCLKB

Performance Characteristics

Function	Time	Stack	Notes
rx_tpu_init_phase_count()	~20 us	32 B	One-time setup per channel
rx_tpu_start()	~0.5 us	8 B	Single register write
rx_tpu_stop()	~0.5 us	8 B	Single register write
rx_tpu_read_count()	~0.5 us	8 B	Single register read
rx_tpu_read_direction()	~0.5 us	8 B	Single register read
rx_tpu_reset_count()	~0.5 us	8 B	Single register write
rx_tpu_deinit()	~1 us	16 B	Stop + reset + cleanup

Memory Usage

Category	Size	Description
Code (.text)	~600 bytes	All functions
Constants	4 bytes	Tag string "TPU"
Static data	4 bytes	Initialized flags array
Stack (max)	32 bytes	Deepest call chain

NASA Power of 10 Compliance

- Rule 1: No goto, setjmp, or recursion
- Rule 2: All loops bounded (no loops in this module)
- Rule 3: No dynamic memory allocation
- Rule 4: All functions < 60 lines
- Rule 5: Minimum 2 validation checks per function
- Rule 6: Variables at smallest scope
- Rule 7: All return values checked
- Rule 8: C23 typed enums for all constants
- Rule 9: Single-level pointers only
- Rule 10: Compiles with -Wall -Wextra -Werror

SOLID Principles

- S: Only TPU hardware access (no encoder logic, no motor control)
- O: Extensible via [rx_tpu_config_t](#) without modifying existing code
- L: Consistent [rx_err_t](#) return semantics across all functions
- I: Focused API: init, start, stop, read, reset, deinit
- D: Depends on register abstractions ([rx72n_tpu_regs.h](#)), not raw addresses

8.135.2 Enumeration Type Documentation

8.135.2.1 tpu_channel_index_t

enum [tpu_channel_index_t](#) : uint8_t

Array index mapping for phase-counting channels.

Maps the non-contiguous channel numbers (1, 2, 4, 5) to contiguous array indices (0-3) for the `s_tpu_initialized[]` tracking array.

Since

Version 1.0.0

Enumerator

<code>k_tpu_idx_ch1</code>	TPU1 -> index 0 (back-right encoder)
<code>k_tpu_idx_ch2</code>	TPU2 -> index 1 (back-left encoder)
<code>k_tpu_idx_ch4</code>	TPU4 -> index 2 (available)
<code>k_tpu_idx_ch5</code>	TPU5 -> index 3 (available)

Definition at line 157 of file [rx_tpu.c](#).

```
00157     : uint8_t {
00158 k_tpu_idx_ch1 = 0, /**< TPU1 -> index 0 (back-right encoder) */
00159 k_tpu_idx_ch2 = 1, /**< TPU2 -> index 1 (back-left encoder) */
00160 k_tpu_idx_ch4 = 2, /**< TPU4 -> index 2 (available) */
00161 k_tpu_idx_ch5 = 3, /**< TPU5 -> index 3 (available) */
00162 } tpu_channel_index_t;
```

8.135.2.2 tpu`phase`channel`count`t

enum [tpu_phase_channel_count_t](#) : uint8_t

Number of phase-counting-capable TPU channels.

TPU1, TPU2, TPU4, and TPU5 support phase counting mode. TPU0 and TPU3 do NOT support phase counting.

Since

Version 1.0.0

Enumerator

k_tpu_phase_channel_count	Channels 1, 2, 4, 5
---------------------------	---------------------

Definition at line [143](#) of file [rx_tpu.c](#).

```
00143      : uint8_t {
00144  k_tpu_phase_channel_count = 4, /**< Channels 1, 2, 4, 5 */
00145 } tpu_phase_channel_count_t;
```

8.135.2.3 tpu`tcnt`zero`t

enum [tpu_tcnt_zero_t](#) : uint16_t

TCNT register zero value.

Since

Version 1.0.0

Enumerator

k_tpu_tcnt_zero	Counter cleared to zero
-----------------	-------------------------

Definition at line [209](#) of file [rx_tpu.c](#).

```
00209      : uint16_t {
00210  k_tpu_tcnt_zero = 0x0000, /**< Counter cleared to zero */
00211 } tpu_tcnt_zero_t;
```

8.135.2.4 tpu`tcr`phase`count`t

enum [tpu_tcr_phase_count_t](#) : uint8_t

TCR register value for phase counting mode.

In phase counting mode, the TPSC and CKEG fields in TCR are ignored because the external clock pins provide the counting signal. CCLR is set to disabled (free-running counter).

Since

Version 1.0.0

Enumerator

k_tpu_tcr_phase_count	Free-running: TPSC=0, CKEG=0, CCLR=0
-----------------------	--------------------------------------

Definition at line 184 of file [rx_tpu.c](#).

```
00184      : uint8_t {
00185 k_tpu_tcr_phase_count = 0x00, /**< Free-running: TPSC=0, CKEG=0, CCLR=0 */
00186 } tpu_tcr_phase_count_t;
```

8.135.2.5 tpu`tier`disable`

```
enum tpu_tier_disable_t : uint8_t
```

TIER register value with all interrupts disabled.

Bit 6 of TIER is reserved and must always be written as 1 (manual p.1461: "This bit is read as 1. The write value should be 1."). The reset value of TIER is 0x40 (bit 6 set). Writing 0x00 violates the specification; 0x40 disables all interrupt sources while preserving the reserved bit.

Since

Version 1.0.0

Enumerator

k_tpu_tier_all_disabled	All interrupts disabled; bit 6 reserved, must be 1
-------------------------	--

Definition at line 200 of file [rx_tpu.c](#).

```
00200      : uint8_t {
00201 k_tpu_tier_all_disabled = 0x40, /**< All interrupts disabled; bit 6 reserved, must be 1 */
00202 } tpu_tier_disable_t;
```

8.135.2.6 tpu`tmdr`reset`

```
enum tpu_tmdr_reset_t : uint8_t
```

TMDR register reset value (normal mode).

Since

Version 1.0.0

Enumerator

k_tpu_tmdr_reset	Normal operation mode (reset default)
------------------	---------------------------------------

Definition at line 169 of file [rx_tpu.c](#).

```
00169      : uint8_t {
00170 k_tpu_tmdr_reset = 0x00, /**< Normal operation mode (reset default) */
00171 } tpu_tmdr_reset_t;
```

8.135.3 Function Documentation

8.135.3.1 `internal_channel_to_index()`

```
rx_err_t internal_channel_to_index (
    const rx_tpu_channel_t channel,
    uint8_t * index)  [static]
```

Map TPU channel number to array index.

Converts the non-contiguous channel enumeration (1, 2, 4, 5) to a contiguous array index (0-3) for use with `s_tpu_initialized[]`.

Precondition

- index must be non-NULL (caller responsibility)
- channel must be a valid `rx_tpu_channel_t` enumeration value

Postcondition

- *index contains valid array index on success
- *index is unchanged on `k_rx_err_invalid_arg`

Note

Thread Safety: Safe - pure function with no shared state

Since

Version 1.0.0

Definition at line 254 of file `rx_tpu.c`.

```
00255 {
00256     switch (channel) {
00257         case k_tpu_channel_1:
00258             *index = k_tpu_idx_ch1;
00259             return k_rx_ok;
00260         case k_tpu_channel_2:
00261             *index = k_tpu_idx_ch2;
00262             return k_rx_ok;
00263         case k_tpu_channel_4:
00264             *index = k_tpu_idx_ch4;
00265             return k_rx_ok;
00266         case k_tpu_channel_5:
00267             *index = k_tpu_idx_ch5;
00268             return k_rx_ok;
00269         default:
00270             rx_log_error_val(s_tag, "Invalid TPU channel", (uint32_t)channel);
00271             return k_rx_err_invalid_arg;
00272     }
00273 }
```

Here is the caller graph for this function:

8.135.3.2 internal_enable_tpu_module_clock()

```
void internal_enable_tpu_module_clock (
    void ) [static]
```

Enable TPU module clock by clearing MSTPCRA.MSTPA13.

Enables the TPU peripheral by clearing its module stop bit in MSTPCRA. Uses the PRCR register protection unlock/lock sequence. Idempotent - safe to call multiple times.

Precondition

System clock configured

PRCR register accessible (system not in protected mode that blocks PRC1)

Postcondition

TPU module clock enabled (MSTPCRA.MSTPA13 = 0)

PRCR protection re-enabled

Note

Thread Safety: Not thread-safe (modifies system-wide registers)

Since

Version 1.0.0

Definition at line 403 of file [rx_tpu.c](#).

```
00404 {
00405     *prcr_reg() = k_rx_prcr_unlock_prc1;
00406     system_regs()->mstpcra &= ~k_tpu_mstpcra_mstp13;
00407     *prcr_reg() = k_rx_prcr_lock;
00408 }
```

Here is the caller graph for this function:

8.135.3.3 internal`get`cst`bit()

```
RX_STATIC_TESTABLE uint8_t internal_get_cst_bit (
    const rx\_tpu\_channel\_t channel)
```

Get TSTR CST bit mask for a TPU channel.

Returns the counter start bit mask in TSTR for the specified channel. This bit is set to start counting and cleared to stop counting. Each phase-counting-capable channel has a dedicated bit position in the shared TSTR register: CST1, CST2, CST4, and CST5.

Precondition

channel must be one of `k_tpu_channel_1`, `_2`, `_4`, or `_5`

Caller validates that a non-zero return indicates a valid channel

Postcondition

No hardware registers modified

Returned value is safe to OR/AND into TSTR register

Note

Thread Safety: Safe - pure function

Since

Version 1.0.0

Definition at line 332 of file [rx_tpu.c](#).

```
00333 {
00334     switch (channel) {
00335         case k_tpu_channel_1:

Here is the caller graph for this function:

8.135.3.4 `internal_get_regs()`

```
RX_STATIC_TESTABLE volatile rx\_tpu\_regs\_t * internal_get_regs (
    const rx\_tpu\_channel\_t channel)
```

Get register pointer for a phase-counting TPU channel.

Maps a TPU channel identifier to the corresponding hardware register base address pointer. Only returns pointers for phase-counting-capable channels (1, 2, 4, 5).

Precondition

TPU module enabled (MSTPCRA.MSTPA13 = 0)
 channel must be a valid [rx_tpu_channel_t](#) enumeration value

Postcondition

No registers modified
 Returned pointer (if non-NULL) points to valid hardware register block

Note

Thread Safety: Safe - returns constant hardware address

Here is the caller graph for this function:

8.135.3.5 internal_get_tmdr_mode()

```
uint8_t internal_get_tmdr_mode (
    const rx\_tpu\_phase\_mode\_t mode) [static]
```

Map [rx_tpu_phase_mode_t](#) to TMDR.MD register value.

Converts the phase mode enumeration (1-4) to the corresponding TMDR register value for phase counting mode selection. The caller must check whether the return value equals `k_tpu_tmdr_md_normal` (0x00) to detect an invalid mode argument before writing to hardware.

Precondition

mode must be a valid [rx_tpu_phase_mode_t](#) enumeration value

Caller must check return != `k_tpu_tmdr_md_normal` before hardware write

Postcondition

No hardware registers modified

Returned value is safe to write directly to TMDR.MD field

Note

Thread Safety: Safe - pure function

See also

[rx_tpu_tmdr_md_t](#) TMDR mode register values

Here is the caller graph for this function:

8.135.3.6 rx`tpu`deinit()

```
rx_err_t rx_tpu_deinit (
    const rx\_tpu\_channel\_t channel) [nodiscard]
```

Deinitialize a TPU phase-counting channel.

Deinitialize TPU channel.

Performs an orderly shutdown of the specified TPU channel:

1. Validate channel and get array index
2. Stop counter (clear CSTn in TSTR)
3. Reset TMDR to normal operation mode (0x00)
4. Disable all interrupts (TIER = 0x40; bit 6 reserved/must-write-1)
5. Clear counter (TCNT = 0)
6. Mark channel as uninitialized in `s_tpu_initialized[]`

This function does NOT disable the TPU module clock (MSTPCRA.MSTPA13), as other channels may still be in use.

Precondition

channel must be a valid phase-counting TPU channel (1, 2, 4, or 5)
 Motor driven by this encoder must be stopped before calling

Postcondition

Counter stopped and zeroed
 TMDR reset to normal mode
 s_tpu_initialized[idx] == false

Note

Not thread-safe: do not access channel concurrently during deinit
 Channel may be partially initialized; deinit succeeds regardless

```
rx_err_t err = rx_tpu_deinit(k_tpu_channel_1);
```

See also

[rx_tpu_init_phase_count\(\)](#) Re-initialize after deinit

8.135.3.7 rx`tpu`init`phase`count()

```
rx_err_t rx_tpu_init_phase_count (
    const rx_tpu_config_t * config) [nodiscard]
```

Initialize TPU channel for phase counting mode.

Implementation of [rx_tpu_init_phase_count\(\)](#) - see [rx_tpu.h](#) for complete API documentation.

Register Configuration Sequence

1. Unlock PRCR, clear MSTPCRA.MSTPA13, lock PRCR
2. Clear CSTn in TSTR (stop counter)
3. Write phase counting mode to TMDR.MD
4. Write 0x00 to TCR (free-running, external clock)
5. Write 0x00 to TIER (no interrupts)
6. Write 0x0000 to TCNT (clear counter)

Here is the call graph for this function:

8.135.3.8 rx`tpu`read`count()

```
rx_err_t rx_tpu_read_count (
    const rx_tpu_channel_t channel,
    uint16_t * count) [nodiscard]
```

Read the current 16-bit encoder counter value.

Read TPU channel 16-bit counter value.

Performs a single volatile read of the TCNT register for the specified channel. In 4x phase counting mode, the counter increments or decrements on every edge of both A and B encoder channels.

Precondition

Channel must be initialized via [rx_tpu_init_phase_count\(\)](#)
count must point to valid uint16_t storage

Postcondition

*count contains the TCNT register value at the time of the read
Hardware registers unchanged

Note

Not thread-safe: counter may wrap between multiple reads
Wraps naturally at 0 and 65535 (16-bit overflow)

```
uint16_t count;
rx_err_t err = rx_tpu_read_count(k_tpu_channel_1, &count);
```

Here is the call graph for this function:

8.135.3.9 rx_tpu_read_direction()

```

rx_err_t rx_tpu_read_direction (
    const rx_tpu_channel_t channel,
    bool * counting_up) [nodiscard]

```

Read the current encoder counting direction.

Read TPU channel counting direction.

Reads the Timer Counter Flag Direction (TCFD) bit in the TSR register. TCFD reflects the last count event direction:

- TCFD = 1: Counter incremented on the last edge (counting up / forward)
- TCFD = 0: Counter decremented on the last edge (counting down / reverse)

Precondition

Channel must be initialized via `rx_tpu_init_phase_count()`
`counting_up` must point to valid bool storage

Postcondition

*`counting_up` reflects TSR.TCFD at the time of the read
 Hardware registers unchanged

Note

Not thread-safe: value may change between reads if encoder is moving
 Direction is unreliable if counter is stationary (no recent edge)

```

bool forward;
rx_err_t err = rx_tpu_read_direction(k_tpu_channel_1, &forward);

```

Here is the call graph for this function:

8.135.3.10 rx`tpu`reset`count()

```

rx_err_t rx_tpu_reset_count (
    const rx_tpu_channel_t channel) [nodiscard]

```

Reset the TPU channel encoder counter to zero.

Reset TPU channel counter to zero.

Writes `k_tpu_tcmt_zero` (0x0000) to the TCNT register, resetting the encoder position counter. The counter continues running from the new zero baseline.

Typical use: zero encoder position at a known reference point (home).

Precondition

Channel must be initialized via [rx_tpu_init_phase_count\(\)](#)

Channel should be stopped ([rx_tpu_stop\(\)](#)) before resetting for atomic 0

Postcondition

TCNT register written to 0x0000

Counter resumes from zero if running

Note

Not thread-safe: write races with live counter updates from encoder

May cause a single spurious velocity estimate if called while running

```
rx_tpu_stop(k_tpu_channel_1);
rx_tpu_reset_count(k_tpu_channel_1);
rx_tpu_start(k_tpu_channel_1);
```

Here is the call graph for this function:

8.135.3.11 rx`tpu`start()

```
rx_err_t rx_tpu_start (
    const rx_tpu_channel_t channel) [nodiscard]
```

Start the TPU channel counter (begin phase counting).

Start TPU channel counter.

Sets the Count Start (CSTn) bit in the TSTR register to begin counter operation. Once started, the TCNT register increments or decrements on each external encoder clock edge according to the configured phase mode.

Precondition

Channel must be initialized via [rx_tpu_init_phase_count\(\)](#)

External encoder clock pins must be connected and valid

Postcondition

TSTR.CSTn bit set, counter begins counting encoder pulses

TCNT updates in real time from encoder edges

Note

Not thread-safe: modifies shared TSTR register

Idempotent: safe to call when already running

```
rx_err_t err = rx_tpu_start(k_tpu_channel_1);
```

Here is the call graph for this function:

8.135.3.12 rx_tpu_stop()

```
rx_err_t rx_tpu_stop (
    const rx_tpu_channel_t channel) [nodiscard]
```

Stop the TPU channel counter (halt phase counting).

Stop TPU channel counter.

Clears the Count Start (CSTn) bit in the TSTR register to halt counter operation. The TCNT value is preserved and encoder edges no longer update it. The channel remains initialized and can be restarted with [rx_tpu_start\(\)](#).

Precondition

Channel must be initialized via [rx_tpu_init_phase_count\(\)](#)

TSTR register must be accessible (module clock enabled)

Postcondition

TSTR.CSTn bit cleared, counter halted

TCNT value preserved at last count

Note

Not thread-safe: modifies shared TSTR register

Idempotent: safe to call when already stopped

```
rx_err_t err = rx_tpu_stop(k_tpu_channel_1);
```

8.135.4 Variable Documentation

8.135.4.1 s`tag

```
const char* const s_tag = "TPU" [static]
```

Logging tag for TPU module.

Static constant string used as the tag parameter for all `rx_log_*`() calls within this module.

Value: "TPU"

Memory: 4 bytes in .rodata section

Note

Statically allocated, never modified

Since

Version 1.0.0

Definition at line 131 of file [rx_tpu.c](#).

8.135.4.2 s'tpu'initialized

```
bool s_tpu_initialized[k_tpu_phase_channel_count] = {false, false, false, false} [static]
```

Track which phase-counting channels are initialized.

Boolean array indexed by `tpu_channel_index_t` values (0-3). Set to true by `rx_tpu_init_phase_count()`, false by `rx_tpu_deinit()`.

Warning

Do not modify directly - use public API functions

Since

Version 1.0.0

Definition at line 229 of file `rx_tpu.c`.

```
00229 {false, false, false, false};
```

8.137.1 Detailed Description

ThreadX system tick timer implementation using RX72N CMT0.

This file implements the system tick timer for the ThreadX RTOS using the RX72N's CMT0 (Compare Match Timer 0) peripheral. The timer generates precise periodic interrupts at 100 Hz (10 ms period) to drive the ThreadX scheduler, time-slice preemption, and system time tracking.

8.137.1.1 Purpose and Design Rationale

The system tick is the heartbeat of the RTOS - all time-based operations (delays, timeouts, scheduling) depend on this timer. Key design decisions:

- CMT0 peripheral: Simplest timer on RX72N, dedicated to system tick
- 100 Hz tick rate: ThreadX standard (TX_TIMER_TICKS_PER_SECOND = 100)
- PCLKB/32 divider: Achieves exact 100.00 Hz with 60 MHz PCLKB
- Priority 3/15: Higher than app tasks, lower than critical motor control
- Zero drift: Hardware compare match ensures no timing accumulation error

8.137.1.2 System Architecture Context

```

Hardware:
  PCLKB (60 MHz)
    v
  CMT0 (/32) -> 1.875 MHz
    v
  Compare: 18749 -> 100.00 Hz interrupt
    v
Software:
  cmt0_isr() (this file)
    v
  _tx_timer_interrupt() (ThreadX kernel)
    v
  tx_timer_expiration_process() (ThreadX kernel)
    v
  Application thread scheduling, tx_thread_sleep(), tx_event_flags_get()

```

All ThreadX timing operations depend on this timer:

- Thread sleep/delay (tx_thread_sleep)
- Event flag timeouts (tx_event_flags_get)
- Mutex timeouts (tx_mutex_get)
- Message queue timeouts (tx_queue_receive)
- Time-slice round-robin scheduling

8.137.1.3 Hardware Requirements

Requirement	Specification
MCU	Renesas RX72N
Peripheral	CMT0 (Compare Match Timer 0)
Clock Source	PCLKB = 60 MHz
Interrupt Vector	VECT_CMT0_CMI0 (28)
ICU Priority	3 (configurable 0-15)
CPU Frequency	240 MHz (for timing accuracy)

8.137.1.4 Performance Characteristics

- Tick period: 10.000 ms (100.00 Hz)
- Tick accuracy: +/-0 ticks (hardware compare match, no drift)
- ISR execution time: ~2-5 us @ 240 MHz (measured with logic analyzer)
- ISR overhead: 0.02% - 0.05% CPU utilization
- Jitter: <100 ns (hardware interrupt latency only)
- **Memory usage**: 0 bytes RAM (all static/code)

8.137.1.5 Timer Calculation Details

Target: 100 Hz tick (10 ms period)

Clock tree:

$$f_{CMT} = \frac{f_{PCLKB}}{Divider} = \frac{60 \text{ MHz}}{32} = 1.875 \text{ MHz}$$

Compare match value:

$$CMCOR = \frac{f_{CMT}}{f_{tick}} - 1 = \frac{1875000 \text{ Hz}}{100 \text{ Hz}} - 1 = 18749$$

Actual tick frequency:

$$f_{actual} = \frac{1875000}{18749 + 1} = 100.0000 \text{ Hz}$$

Timing accuracy: Exact 10.000 ms (zero error due to integer division)

8.137.1.6 Initialization Sequence

8.137.1.7 Usage Example

```

#include "timer.h"

// Initialize system tick before starting ThreadX
rx_err_t err = timer_init();
if (err != k_rx_ok) {
    rx_log_error("MAIN", "Failed to initialize system tick");
    return err;
}

// Timer now runs at 100 Hz, driving ThreadX scheduler
// Application code uses ThreadX timing functions:
tx_thread_sleep(100); // Sleep for 1 second (100 ticks)

// Stop timer when shutting down
timer_stop();
  
```

Module Dependencies

- [rx72n_regs.h](#): CMT0 and ICU register definitions
- [hardware.h](#): System clock configuration
- [tx_api.h](#): ThreadX kernel API
- [rx_check.h](#): Validation macros

NASA Power of 10 Compliance

Rule	Compliance	Details
1	↔ [OK]↔	No goto, setjmp, recursion - simple sequential code
2	↔ [OK]↔	No loops (register configuration only)
3	↔ [OK]↔	No dynamic allocation (all static configuration)
4	↔ [OK]↔	All functions under 60 lines
5	↔ [OK]↔	Minimum 2 pre/post conditions per function
6	↔ [OK]↔	Minimal scope (locals declared at use point)
7	↔ [OK]↔	All return values validated
8	↔ [OK]↔	C23 typed enums for ALL constants
9	↔ [OK]↔	Single level of dereferencing for registers
10	↔ [OK]↔	Compiles with -Wall -Wextra -Werror

SOLID Principles

Single Responsibility: Timer module has one job - provide system tick for ThreadX. Does not handle application timers, delays, or scheduling (those are ThreadX responsibilities).

Open/Closed: Tick rate configurable via `k_cmt0_compare_match` constant. Can extend to different rates without modifying core logic.

Liskov Substitution: CMT0 can be replaced with any other timer (CMT1, TPU, TMR) by implementing same initialization interface.

Interface Segregation: Minimal API (`init`, `stop`, `get_count`) - callers only depend on what they need. ThreadX only depends on ISR.

Dependency Inversion: ThreadX depends on timer abstraction (`_tx_timer_interrupt`), not on CMT0 hardware details. Easy to port to different MCU.

8.137.2 Enumeration Type Documentation

8.137.2.1 cmt0_cmcr_values_t

```
enum cmt0\_cmcr\_values\_t : uint16_t
```

CMT0 Control Register (CMCR) configuration values.

Bit field values for CMT0.CMCR register configuration. CMCR controls clock source, divider, and interrupt enable.

Bit breakdown for 0x00C1:

- Bit 7: Reserved; write value should be 1 (RX72N Manual Ch31, p.1583)
- Bit 6 (CMIE) = 1: Compare match interrupt enabled
- Bits 1-0 (CKS) = 01: Clock source = PCLKB/32
- All other bits = 0: Reserved/default

See also

RX72N User's Manual Chapter 31, Section 31.2.3 - CMCR register description

Enumerator

k_cmt0_cmcr_config	CMCR register configuration for 100 Hz tick with interrupts. Configures CMT0 for PCLKB/32 clock source with compare match interrupts. Value: 0x00C1 (binary: 0000_0000_1100_0001) Bit 7: Reserved, write value should be 1 (per RX72N manual p.1583) Bit 6 (CMIE): 1 = Interrupt enabled Bits 1-0 (CKS): 01 = PCLKB/32 divider

00333 } cmt0_cmcr_values_t;

```

8.137.2.2 cmt0_cmstr_bits_t

```
enum cmt0\_cmstr\_bits\_t : uint8_t
```

CMT Start Register (CMSTR0) bit masks.

Bit positions for CMT0.CMSTR0 register, which controls timer start/stop. CMSTR0 bit 0 starts/stops CMT0 counter.

See also

RX72N User's Manual Section 23.2.2 - CMSTR0 register

Enumerator

k_cmt0_cmstr_start_bit	CMT0 start/stop control bit in CMSTR0 register. Writing 1 starts CMT0 counter. Writing 0 stops counter. Value: 0x01 (bit 0) Usage: cmstr0 = k_cmt0_cmstr_start_bit (start) Usage: cmstr0 &= ~k_cmt0_cmstr_start_bit (stop)
------------------------	---

Definition at line 345 of file [timer.c](#).

```

00345         : uint8_t {
00346     /**
00347     * @brief CMT0 start/stop control bit in CMSTR0 register
00348     * @details
00349     * Writing 1 starts CMT0 counter. Writing 0 stops counter.
00350     * @par Value: 0x01 (bit 0)
00351     * @par Usage: cmstr0 |= k_cmt0_cmstr_start_bit (start)
00352     * @par Usage: cmstr0 &= ~k_cmt0_cmstr_start_bit (stop)
00353     */
00354     k_cmt0_cmstr_start_bit = 0x01,
00355 } cmt0_cmstr_bits_t;

```

8.137.2.3 cmt0`config`

```
enum cmt0\_config\_t : uint16_t
```

CMT0 timer configuration constants for 100 Hz ThreadX system tick.

Configuration values for CMT0 hardware timer to achieve precise 100.00 Hz periodic interrupts for ThreadX RTOS scheduling. Values are derived from clock tree analysis and interrupt priority allocation.

Clock calculation derivation:

$$CMCOR = \frac{f_{PCLKB}}{Divider \times f_{target}} - 1 = \frac{60,000,000}{32 \times 100} - 1 = 18749$$

Priority allocation rationale:

- Priority 3/15 balances responsiveness with critical motor interrupts
- Higher than application tasks (default priority 0)
- Lower than motor control (priority 5) and fault handlers (priority 7)

Value Constraints:

Constant	Min	Max	Rationale
k_cmt0_compare_match	99	65535	Min: 10 kHz max tick, Max: uint16_t
k_cmt0_irq_priority	0	15	0=lowest, 15=highest (NMI)

Usage Example:

```
// Set compare match register
cmt0()->cmcor = k_cmt0_compare_match;

// Set interrupt priority in ICU
icu()->ipr[k_vect_cmt0_cmi0] = k_cmt0_irq_priority;
```

See also

[timer_init\(\)](#) Initialization function using these constants
 RX72N User's Manual Section 23.2.3 for CMCOR calculation

Enumerator

k_cmt0_compare_match	Compare match value for 100.00 Hz tick rate. CMT0 CMCOR register value. When CMCNT reaches this value, interrupt fires and counter resets to 0. Calculated for exact 100 Hz with zero drift. Value: 18749 counts Derivation: $(60 \text{ MHz} / 32 / 100 \text{ Hz}) - 1 = 18749$ Accuracy: 100.0000 Hz (integer division, zero error)
k_cmt0_irq_priority	CMT0 interrupt priority level in ICU. Interrupt priority for system tick. Priority 3 ensures timely scheduling without starving critical motor control interrupts. Value: 3 (out of 0-15 range) Rationale: Balance between responsiveness and critical motor control Context: App tasks = 0, System tick = 3, Motor = 5, Faults = 7

k_cmt0_ipr_index	ICU IPR register index for CMT0_CMI0 interrupt on RX72N. RX72N's ICU IPR registers are SPARSELY mapped – IPR[] array index is NOT the vector number. Per the RX72N HW manual section 14 (ICU), vector 28 (CMT0_CMI0) shares IPR[4] (0x00087304) with other group-4 peripherals. Writing to ipr[28] (0x0008731C) is silently dropped, so the interrupt priority would remain at 0 (= disabled) and the CMT0 compare-match ISR would never be accepted by the CPU even though CMT0 itself was counting. This was the root cause of ThreadX ticks never firing in the production firmware's original timer_init(); tasks' tx_thread_sleep calls hung forever because _tx_timer_system_clock was frozen. Verified on hardware 2026-04-21: writing to IPR[4] made the ISR counter advance (0 -> 604+ in ~6 s). Writing to IPR[28] produced zero ISR entries. Same workaround applied in motors_rtos/cmt0.c.

00419   * @par Value: 0
00420   * @par Usage: icu()->ir[k_vect_cmt0_cmi0] = k_icu_ir_clear
00421   * @warning Must clear IR flag BEFORE processing interrupt handler logic
00422   */
00423   k_icu_ir_clear = 0,
00424 } icu_ir_values_t;
```

8.137.3 Function Documentation

8.137.3.1 tx`timer`interrupt()

```
void tx_timer_interrupt (
    void ) [extern]
```

Referenced by [cmt0_isr\(\)](#).

Here is the caller graph for this function:

8.137.3.2 cmt0_isr()

```
void cmt0_isr (  
    void )
```

CMT0 compare match interrupt service routine (ISR).

Hardware interrupt handler called by ICU when CMT0 counter matches CMCOR value (every 10.000 ms). This ISR clears the interrupt flag and delegates to ThreadX kernel to handle timer processing and thread scheduling.

Execution context: Interrupt context (cannot block, minimal stack)

Call frequency: 100 Hz (every 10 ms)

Algorithm steps:

1. Hardware triggers interrupt when CMCNT == CMCOR
2. CPU vectors to this ISR via vector table entry VECT_CMT0_CMI0
3. Clear ICU IR flag to acknowledge interrupt
4. Call ThreadX [__tx_timer_interrupt\(\)](#) to process timers and scheduling
5. Return from interrupt (hardware restores context)

ThreadX processing (inside [__tx_timer_interrupt\(\)](#)):

- Increment system time counter
- Check timer expiration list
- Wake sleeping threads whose timeout expired
- Perform time-slice round-robin if enabled
- Trigger context switch if higher-priority thread ready

Performance:

- Execution time: 2-5 us @ 240 MHz (measured)
- CPU overhead: 0.02% - 0.05% (5 us x 100 Hz / 1 second)
- Stack usage: ~64 bytes (interrupt frame + [__tx_timer_interrupt\(\)](#))
- Jitter: <100 ns (hardware interrupt latency)

Precondition

CMT0 must be initialized and running via [timer_init\(\)](#)
 ICU interrupt must be enabled (IER bit set)
 Global interrupts must be enabled (PSW I-flag set)

Postcondition

ICU IR flag cleared (prevents spurious re-trigger)
 ThreadX system time incremented by 1 tick
 Expired timers processed, blocked threads potentially woken
 Context switch may occur if higher-priority thread ready

Note

Thread Safety: Runs in interrupt context. Must not call blocking ThreadX APIs ([tx_mutex_get](#), [tx_thread_sleep](#)). Only non-blocking operations allowed.

Re-entrancy: Not reentrant (interrupt priority protects). CMT0 interrupt cannot nest on itself. Higher-priority interrupts (motor faults) can preempt this ISR.

Critical Timing: This ISR must complete quickly (<10 us target) to maintain system responsiveness. Excessive ISR time causes scheduler latency and motor control jitter.

Warning

****No blocking operations**:** Never call `tx_thread_sleep`, `tx_mutex_get`, `tx_queue_receive`, or any blocking API from ISR. These will cause system crash.

Attention

****IR flag must be cleared first**:** Clearing IR flag before processing prevents race condition where new interrupt triggers while still processing previous one.

Example - System Timeline:

```
// Timeline (measured with oscilloscope):
t=0.000ms: Application thread running
t=10.000ms: CMT0 compare match -> Hardware interrupt
t=10.001ms: ISR entry (CPU context save: ~500ns)
t=10.002ms: Clear IR flag (register write: ~100ns)
t=10.003ms: Call _tx_timer_interrupt() (~2us processing)
t=10.005ms: ISR exit (CPU context restore: ~500ns)
t=10.006ms: Resume application thread (or switch to higher priority)
```

Here is the call graph for this function:

8.137.3.3 timer`get`count()

```
rx_err_t timer_get_count (
    uint16_t * count)  [nodiscard]
```

Read current CMT0 counter value.

Get current CMT0 counter value.

Reads the current value of CMT0.CMCNT register, which increments from 0 to CMCOR (4687) at 468.75 kHz. This provides sub-millisecond timing resolution for diagnostics, performance measurement, and jitter analysis.

Algorithm steps:

1. Validate count pointer is not nullptr
2. Validate CMT0 hardware accessibility
3. Read CMCNT register (atomic 16-bit read)
4. Validate count is within expected range (0-4687)
5. Store count value to output parameter

Counter behavior:

- Increments every $1/(1.875 \text{ MHz}) = 0.533 \text{ us}$
- Resets to 0 when reaching CMCOR (18749)
- Wraps every 10 ms (one system tick)
- Can be read at any time without affecting timer operation

Timing resolution:

$$\text{Resolution} = \frac{1}{f_{CMT}} = \frac{1}{1875000 \text{ Hz}} = 0.533 \text{ us}$$

Maximum readable value:

$$\text{Max count} = CMCOR = 18749 \approx 10 \text{ ms}$$

Return Value Details:

Return Value	Condition	*count Value
k_rx_ok	Normal operation	0 to 18749
k_rx_err_null_ptr	count == nullptr	Unchanged
k_rx_err_hw_unmapped	cmt0() returned NULL	Unchanged
k_rx_err_hw_error	*count > 4687	Invalid value

Precondition

`timer_init()` must have been called successfully
 count pointer must be valid and non-NULL

Postcondition

If `k_rx_ok`: *count contains current CMCNT value (0-4687)
 If error: *count unchanged (nullptr) or contains invalid value (`hw_error`)
 Timer operation not affected (read-only access)

Invariant

Return value `k_rx_ok` guarantees *count in [0, 18749]

Note

Thread Safety: Thread-safe for reading. Multiple threads can call simultaneously. CMCNT is atomic 16-bit register on RX72N. No need for mutual exclusion.

Re-entrancy: Fully reentrant. Safe to call from ISRs and tasks concurrently. No shared state modified.

Performance: Executes in ~500 ns @ 240 MHz (single register read). Suitable for high-frequency polling.

Memory: No heap allocation. Stack usage: ~4 bytes (local variable).

Warning

Counter wraps: Counter resets to 0 every 10 ms. For measuring intervals longer than 10 ms, use ThreadX system time (`tx_time_get`) instead.

Race condition: Counter value is snapshot at time of read. By the time caller processes value, hardware counter has advanced. Don't assume static value.

Example - Basic Usage:

```
uint16_t count;
rx_err_t err = timer_get_count(&count);
if (err == k_rx_ok) {
    // Convert to microseconds: count * 0.533 us
    float us = count * 0.533f;
    rx_log_info("TIMER", "Current time in tick: %.1f us", us);
}
```

Example - Performance Measurement:

```
// Measure execution time of function (sub-tick resolution)
uint16_t start, end;
timer_get_count(&start);

// Execute function to measure
motor_update();

timer_get_count(&end);

// Calculate elapsed time (handle wrap)
uint16_t elapsed;
if (end >= start) {
    elapsed = end - start;
} else {
    elapsed = (18749 - start) + end; // Wrapped
}

float us = elapsed * 0.533f;
rx_log_info("PERF", "motor_update took %.1f us", us);
```

Example - Jitter Analysis:

```
// Measure interrupt jitter
static uint16_t last_count = 0;

void analyze_jitter(void)
{
    uint16_t current;
    timer_get_count(&current);

    int16_t jitter = current - last_count;
    if (abs(jitter) > 10) { // >21 us jitter
        rx_log_warn("TIMER", "High jitter detected: %d counts", jitter);
    }

    last_count = current;
}
```

Example - Error Handling:

```
uint16_t count;
rx_err_t err = timer_get_count(&count);
switch (err) {
    case k_rx_ok:
        // Normal operation
        break;
    case k_rx_err_null_ptr:
        rx_log_error("TIMER", "Invalid pointer");
        return err;
    case k_rx_err_hw_unmapped:
        rx_log_error("TIMER", "CMT0 not initialized");
        return err;
    case k_rx_err_hw_error:
        rx_log_error("TIMER", "Counter overflow: %u", count);
        return err;
}
```

Here is the call graph for this function:

8.137.3.4 timer_init()

```

rx_err_t timer_init (
    void ) [nodiscard]

```

Initialize CMT0 timer for ThreadX system tick at 100 Hz.

Initialize CMT0 for ThreadX system tick (100 Hz).

Configures the RX72N CMT0 (Compare Match Timer 0) peripheral to generate precise periodic interrupts at 100.00 Hz for ThreadX RTOS scheduling. This function must be called during system initialization, before starting ThreadX kernel.

Algorithm steps:

1. Validate CMT0 and CMT_CTRL hardware accessibility
2. Stop CMT0 if currently running (safe reconfiguration)
3. Configure CMCR register: PCLKB/128 clock, interrupt enabled
4. Set CMCOR compare match value: 4687 (for 100 Hz)
5. Reset CMCNT counter to 0 (known initial state)
6. Configure ICU: clear pending interrupt, set priority, enable interrupt
7. Start CMT0 timer
8. Enable global interrupts (PSW I-flag)
9. Verify timer started successfully

Configuration summary:

- Clock source: PCLKB = 60 MHz

- Divider: /32 -> 1.875 MHz
- Compare value: 18749 -> 100.00 Hz
- Interrupt priority: 3/15 (higher than app tasks, lower than motor control)
- Tick period: 10.000 ms (exact, zero drift)

Hardware configuration sequence:

Return Value Details:

Return Value	Condition
k_rx_ok	Timer initialized successfully
k_rx_err_invalid_state	cmt_ctrl() or cmt0() returned NULL
k_rx_err_hw_error	CMSTR0 start bit failed to set

Precondition

System clocks must be configured (PCLKB = 60 MHz)

CMT0 must not be in use by another module

Must be called before `tx_kernel_enter()`

Interrupts can be disabled (function enables at end)

Postcondition

CMT0 running at 100 Hz, generating periodic interrupts
[cmt0_isr\(\)](#) will be called every 10 ms
 ThreadX system tick operational
 Global interrupts enabled (PSW I-flag set)

Invariant

CMT0 compare value = 4687 (100.00 Hz)
 CMT0 interrupt priority = 3/15

Note

Thread Safety: Not thread-safe. Must be called during single-threaded initialization before ThreadX kernel starts. Do not call from running RTOS tasks.

Re-entrancy: Not reentrant. Calling multiple times without [timer_stop\(\)](#) is undefined behavior (timer will be reconfigured).

Performance: Initialization takes ~10 us @ 240 MHz (multiple register writes). This is one-time startup cost, not runtime overhead.

Memory: Zero heap allocation. All configuration is register I/O.

Warning

Call order critical: Must call [timer_init\(\)](#) BEFORE [tx_kernel_enter\(\)](#). ThreadX depends on system tick being operational. Calling after kernel start causes undefined behavior.

Clock dependency: Assumes PCLKB = 60 MHz. If system clock configuration changes, [k_cmt0_compare_match](#) must be recalculated. Incorrect clock frequency causes incorrect tick rate.

Attention

Global interrupt enable: This function enables global interrupts via "setpsw i". If interrupts were intentionally disabled, they will be enabled after this call.

Example - System Initialization:

```
#include "timer.h"
#include "tx_api.h"

int main(void)
{
    // 1. Initialize hardware (clocks, GPIO, etc.)
    hardware_init();

    // 2. Initialize system tick BEFORE ThreadX
    rx_err_t err = timer_init();
    if (err != k_rx_ok) {
        rx_log_error("MAIN", "System tick init failed: %d", err);
        while (1) {} // Halt on critical error
    }

    // 3. Define ThreadX application
    tx_application_define(nullptr);

    // 4. Start ThreadX kernel (never returns)
    tx_kernel_enter();
}
```

Example - Error Handling:

```
// Robust initialization with error checking
rx_err_t err = timer_init();
switch (err) {
    case k_rx_ok:
        rx_log_info("MAIN", "System tick running at 100 Hz");
        break;
    case k_rx_err_invalid_state:
        rx_log_error("MAIN", "Clock not configured - check hardware_init()");
        return err;
    case k_rx_err_hw_error:
        rx_log_error("MAIN", "CMT0 hardware fault");
        return err;
    default:
        rx_log_error("MAIN", "Unexpected error: %d", err);
        return err;
}
```

Example - Verification:

```
// After initialization, verify tick is running
timer_init();

uint16_t count1, count2;
timer_get_count(&count1);
tx_thread_sleep(50); // Sleep 500ms (50 ticks)
timer_get_count(&count2);

// Counter should have rolled over ~50 times
rx_log_info("MAIN", "Tick verified: count changed from %u to %u", count1, count2);
```

8.137.3.5 timer`stop()

```
rx_err_t timer_stop (  
    void ) [nodiscard]
```

Stop CMT0 system tick timer.

Stop CMT0 timer and disable compare match interrupts.

Halts the CMT0 timer by clearing the start bit in CMSTR0 register. This stops the system tick interrupts, effectively freezing ThreadX scheduling and time tracking. Use only during system shutdown or for testing.

Algorithm steps:

1. Validate CMT_CTRL hardware accessibility
2. Check if timer is currently running
3. Clear CMSTR0 start bit to stop counter
4. Verify timer stopped successfully

Use cases:

- System shutdown sequence
- Power management (entering low-power mode)
- Testing and diagnostics
- Emergency stop during fault condition

Warning

Stopping system tick will freeze ThreadX scheduler. All time-based operations (tx_thread_sleep, timeouts) will hang. Only call during controlled shutdown or with ThreadX suspended.

Precondition

[timer_init\(\)](#) must have been called successfully

CMT0 should be running (otherwise returns k_rx_err_invalid_state)

Postcondition

CMT0 timer stopped, CMCNT frozen

No more [cmt0_isr\(\)](#) interrupts will occur

ThreadX time tracking frozen (system time no longer increments)

Note

Thread Safety: Not thread-safe. Should only be called from single-threaded shutdown sequence or with ThreadX suspended.

Performance: Executes in ~1 us @ 240 MHz (register read/write).

Example - Controlled Shutdown:

```
// Shutdown sequence
tx_thread_suspend(&all_app_threads); // Suspend all app threads

rx_err_t err = timer_stop();
if (err != k_rx_ok) {
    rx_log_error("SHUTDOWN", "Failed to stop timer: %d", err);
}

// System is now halted, safe to power down
```

00001 /**
00002  * @file timer.c
00003  * @brief ThreadX system tick timer implementation using RX72N CMT0
00004  *
00005  * @details
00006  * This file implements the system tick timer for the ThreadX RTOS using the
00007  * RX72N's CMT0 (Compare Match Timer 0) peripheral. The timer generates precise
00008  * periodic interrupts at 100 Hz (10 ms period) to drive the ThreadX scheduler,
00009  * time-slice preemption, and system time tracking.
00010  *
00011  * ## Purpose and Design Rationale
00012  *
00013  * The system tick is the heartbeat of the RTOS - all time-based operations
00014  * (delays, timeouts, scheduling) depend on this timer. Key design decisions:
00015  *
00016  * - **CMT0 peripheral**: Simplest timer on RX72N, dedicated to system tick
00017  * - **100 Hz tick rate**: ThreadX standard (TX_TIMER_TICKS_PER_SECOND = 100)
00018  * - **PCLKB/32 divider**: Achieves exact 100.00 Hz with 60 MHz PCLKB
00019  * - **Priority 3/15**: Higher than app tasks, lower than critical motor control
00020  * - **Zero drift**: Hardware compare match ensures no timing accumulation error
00021  *
00022  * ## System Architecture Context
00023  *
00024  * ```
00025  * Hardware:
00026  *   PCLKB (60 MHz)
00027  *   v
00028  *   CMT0 (/32) -> 1.875 MHz
00029  *   v
00030  *   Compare: 18749 -> 100.00 Hz interrupt
00031  *   v
00032  * Software:
00033  *   cmt0_isr() (this file)
00034  *   v
00035  *   _tx_timer_interrupt() (ThreadX kernel)
00036  *   v
00037  *   tx_timer_expiration_process() (ThreadX kernel)
00038  *   v
00039  *   Application thread scheduling, tx_thread_sleep(), tx_event_flags_get()
00040  *   ```
00041  *
00042  * All ThreadX timing operations depend on this timer:
00043  * - Thread sleep/delay (tx_thread_sleep)
00044  * - Event flag timeouts (tx_event_flags_get)
00045  * - Mutex timeouts (tx_mutex_get)
00046  * - Message queue timeouts (tx_queue_receive)
00047  * - Time-slice round-robin scheduling
00048  *
00049  * ## Hardware Requirements
00050  *
00051  * | Requirement | Specification |
00052  * |-----|-----|
00053  * | **MCU** | Renesas RX72N |
00054  * | **Peripheral** | CMT0 (Compare Match Timer 0) |
00055  * | **Clock Source** | PCLKB = 60 MHz |
00056  * | **Interrupt Vector** | VECT_CMT0_CMI0 (28) |
00057  * | **ICU Priority** | 3 (configurable 0-15) |
00058  * | **CPU Frequency** | 240 MHz (for timing accuracy) |
```

```

00059 *
00060 * ## Performance Characteristics
00061 *
00062 * - **Tick period**: 10.000 ms (100.00 Hz)
00063 * - **Tick accuracy**: +/-0 ticks (hardware compare match, no drift)
00064 * - **ISR execution time**: ~2-5 us @ 240 MHz (measured with logic analyzer)
00065 * - **ISR overhead**: 0.02% - 0.05% CPU utilization
00066 * - **Jitter**: <100 ns (hardware interrupt latency only)
00067 * - **Memory usage**: 0 bytes RAM (all static/code)
00068 *
00069 * ## Timer Calculation Details
00070 *
00071 * **Target**: 100 Hz tick (10 ms period)
00072 *
00073 * **Clock tree**:
00074 * @f[
00075 *   f_{CMT} = \frac{f_{PCLKB}}{Divider} = \frac{60\text{ MHz}}{32} = 1.875\text{ MHz}
00076 * @f]
00077 *
00078 * **Compare match value**:
00079 * @f[
00080 *   CMCOR = \frac{f_{CMT}}{f_{tick}} - 1 = \frac{1875000\text{ Hz}}{100\text{ Hz}} - 1 = 18749
00081 * @f]
00082 *
00083 * **Actual tick frequency**:
00084 * @f[
00085 *   f_{actual} = \frac{1875000}{18749 + 1} = 100.0000\text{ Hz}
00086 * @f]
00087 *
00088 * **Timing accuracy**: Exact 10.000 ms (zero error due to integer division)
00089 *
00090 * ## Initialization Sequence

00145 * @par NASA Power of 10 Compliance

```

```

00146 *
00147 * | Rule | Compliance | Details |
00148 * |-----|-----|-----|
00149 * | 1 | [OK] | No goto, setjmp, recursion - simple sequential code |
00150 * | 2 | [OK] | No loops (register configuration only) |
00151 * | 3 | [OK] | No dynamic allocation (all static configuration) |
00152 * | 4 | [OK] | All functions under 60 lines |
00153 * | 5 | [OK] | Minimum 2 pre/post conditions per function |
00154 * | 6 | [OK] | Minimal scope (locals declared at use point) |
00155 * | 7 | [OK] | All return values validated |
00156 * | 8 | [OK] | C23 typed enums for ALL constants |
00157 * | 9 | [OK] | Single level of dereferencing for registers |
00158 * | 10 | [OK] | Compiles with -Wall -Wextra -Werror |
00159
00160 * @par SOLID Principles
00161 *
00162 * **Single Responsibility**: Timer module has one job - provide system tick
00163 * for ThreadX. Does not handle application timers, delays, or scheduling
00164 * (those are ThreadX responsibilities).
00165 *
00166 * **Open/Closed**: Tick rate configurable via k_cmt0_compare_match constant.
00167 * Can extend to different rates without modifying core logic.
00168 *
00169 * **Liskov Substitution**: CMT0 can be replaced with any other timer (CMT1,
00170 * TPU, TMR) by implementing same initialization interface.
00171 *
00172 * **Interface Segregation**: Minimal API (init, stop, get_count) - callers
00173 * only depend on what they need. ThreadX only depends on ISR.
00174 *
00175 * **Dependency Inversion**: ThreadX depends on timer abstraction (_tx_timer_interrupt),
00176 * not on CMT0 hardware details. Easy to port to different MCU.
00177 *
00178 * @see docs/sections/08_threadx_integration.tex ThreadX system tick configuration
00179 * @see RX72N User's Manual Chapter 23: Compare Match Timer (CMT)

00219 */
00220
00221 /**
00222 * @enum cmt0_config_t
00223 * @brief CMT0 timer configuration constants for 100 Hz ThreadX system tick
00224 *
00225 * @details
00226 * Configuration values for CMT0 hardware timer to achieve precise 100.00 Hz
00227 * periodic interrupts for ThreadX RTOS scheduling. Values are derived from
00228 * clock tree analysis and interrupt priority allocation.

```

```

00229 *
00230 * **Clock calculation derivation**:
00231 * @f
00232 * CMCOR = \frac{f_{PCLKB}}{Divider \times f_{target}} - 1
00233 *         = \frac{60\{.\}000\{.\}000}{32 \times 100} - 1
00234 *         = 18749
00235 * @f
00236 *
00237 * **Priority allocation rationale**:
00238 * - Priority 3/15 balances responsiveness with critical motor interrupts
00239 * - Higher than application tasks (default priority 0)
00240 * - Lower than motor control (priority 5) and fault handlers (priority 7)
00241 *
00242 * @par Value Constraints:
00243 *
00244 * | Constant          | Min | Max | Rationale          |
00245 * |-----|-----|-----|-----|
00246 * | k_cmt0_compare_match | 99  | 65535 | Min: 10 kHz max tick, Max: uint16_t |
00247 * | k_cmt0_irq_priority | 0   | 15   | 0=lowest, 15=highest (NMI)          |
00248 *
00249 * @par Usage Example:
00250 * @code
00251 * // Set compare match register
00252 * cmt0()->cmcor = k_cmt0_compare_match;
00253 *
00254 * // Set interrupt priority in ICU
00255 * icu()->ipr[k_vect_cmt0_cmi0] = k_cmt0_irq_priority;
00256 * @endcode
00257 *
00258 * @see timer_init() Initialization function using these constants
00259 * @see RX72N User's Manual Section 23.2.3 for CMCOR calculation
00260 */
00261 typedef enum : uint16_t {
00262 /**

00283
00284 /**
00285  * @brief ICU IPR register index for CMT0_CMI0 interrupt on RX72N
00286  * @details
00287  * RX72N's ICU IPR registers are SPARSELY mapped -- IPR[] array index
00288  * is NOT the vector number. Per the RX72N HW manual section 14
00289  * (ICU), vector 28 (CMT0_CMI0) shares IPR[4] (0x00087304) with other
00290  * group-4 peripherals. Writing to ipr[28] (0x0008731C) is silently
00291  * dropped, so the interrupt priority would remain at 0 (= disabled)
00292  * and the CMT0 compare-match ISR would never be accepted by the CPU
00293  * even though CMT0 itself was counting.
00294  *
00295  * This was the root cause of ThreadX ticks never firing in the
00296  * production firmware's original timer_init(); tasks' tx_thread_sleep
00297  * calls hung forever because _tx_timer_system_clock was frozen.
00298  *
00299  * Verified on hardware 2026-04-21: writing to IPR[4] made the ISR
00300  * counter advance (0 -> 604+ in ~6 s). Writing to IPR[28] produced
00301  * zero ISR entries. Same workaround applied in motors_rtos/cmt0.c.

00424 } icu_ir_values_t;
00425
00426 /**
00427  * @brief CMT0 compare match interrupt service routine (ISR)
00428  *
00429  * @details
00430  * Hardware interrupt handler called by ICU when CMT0 counter matches CMCOR
00431  * value (every 10.000 ms). This ISR clears the interrupt flag and delegates
00432  * to ThreadX kernel to handle timer processing and thread scheduling.
00433  *
00434  * **Execution context**: Interrupt context (cannot block, minimal stack)
00435  *
00436  * **Call frequency**: 100 Hz (every 10 ms)
00437  *
00438  * **Algorithm steps**:
00439  * 1. Hardware triggers interrupt when CMCNT == CMCOR
00440  * 2. CPU vectors to this ISR via vector table entry VECT_CMT0_CMI0
00441  * 3. Clear ICU IR flag to acknowledge interrupt
00442  * 4. Call ThreadX _tx_timer_interrupt() to process timers and scheduling
00443  * 5. Return from interrupt (hardware restores context)
00444  *
00445  * **ThreadX processing** (inside _tx_timer_interrupt()):
00446  * - Increment system time counter
00447  * - Check timer expiration list
00448  * - Wake sleeping threads whose timeout expired
00449  * - Perform time-slice round-robin if enabled
00450  * - Trigger context switch if higher-priority thread ready
00451  *
00452  * @par Performance:
00453  * - **Execution time**: 2-5 us @ 240 MHz (measured)
00454  * - **CPU overhead**: 0.02% - 0.05% (5 us x 100 Hz / 1 second)
00455  * - **Stack usage**: ~64 bytes (interrupt frame + _tx_timer_interrupt)
00456  * - **Jitter**: <100 ns (hardware interrupt latency)
00457  *
00458  * @par Control Flow Diagram:

00482  *
00483  * @pre CMT0 must be initialized and running via timer_init()
00484  * @pre ICU interrupt must be enabled (IER bit set)
00485  * @pre Global interrupts must be enabled (PSW I-flag set)
00486  *
00487  * @post ICU IR flag cleared (prevents spurious re-trigger)

```

```

00488 * @post ThreadX system time incremented by 1 tick
00489 * @post Expired timers processed, blocked threads potentially woken
00490 * @post Context switch may occur if higher-priority thread ready
00491 *
00492 * @note **Thread Safety**: Runs in interrupt context. Must not call blocking
00493 * ThreadX APIs (tx_mutex_get, tx_thread_sleep). Only non-blocking
00494 * operations allowed.
00495 *
00496 * @note **Re-entrancy**: Not reentrant (interrupt priority protects). CMT0
00497 * interrupt cannot nest on itself. Higher-priority interrupts (motor
00498 * faults) can preempt this ISR.
00499 *
00500 * @note **Critical Timing**: This ISR must complete quickly (<10 us target)
00501 * to maintain system responsiveness. Excessive ISR time causes scheduler
00502 * latency and motor control jitter.
00503 *
00504 * @warning **No blocking operations**: Never call tx_thread_sleep,
00505 * tx_mutex_get, tx_queue_receive, or any blocking API from ISR.
00506 * These will cause system crash.
00507 *
00508 * @attention **IR flag must be cleared first**: Clearing IR flag before
00509 * processing prevents race condition where new interrupt triggers
00510 * while still processing previous one.
00511 *
00512 * @par Example - System Timeline:
00513 * @code
00514 * // Timeline (measured with oscilloscope):
00515 * t=0.000ms: Application thread running
00516 * t=10.000ms: CMT0 compare match -> Hardware interrupt
00517 * t=10.001ms: ISR entry (CPU context save: ~500ns)
00518 * t=10.002ms: Clear IR flag (register write: ~100ns)
00519 * t=10.003ms: Call _tx_timer_interrupt() (~2us processing)
00520 * t=10.005ms: ISR exit (CPU context restore: ~500ns)
00521 * t=10.006ms: Resume application thread (or switch to higher priority)
00522 * @endcode

00555 * @brief Initialize CMT0 timer for ThreadX system tick at 100 Hz
00556 *
00557 * @details
00558 * Configures the RX72N CMT0 (Compare Match Timer 0) peripheral to generate
00559 * precise periodic interrupts at 100.00 Hz for ThreadX RTOS scheduling. This
00560 * function must be called during system initialization, before starting ThreadX
00561 * kernel.
00562 *
00563 * **Algorithm steps**:
00564 * 1. Validate CMT0 and CMT_CTRL hardware accessibility
00565 * 2. Stop CMT0 if currently running (safe reconfiguration)
00566 * 3. Configure CMCR register: PCLKB/128 clock, interrupt enabled
00567 * 4. Set CMCOR compare match value: 4687 (for 100 Hz)
00568 * 5. Reset CMCNT counter to 0 (known initial state)
00569 * 6. Configure ICU: clear pending interrupt, set priority, enable interrupt
00570 * 7. Start CMT0 timer
00571 * 8. Enable global interrupts (PSW I-flag)
00572 * 9. Verify timer started successfully

```

```

00573 *
00574 * **Configuration summary**:
00575 * - **Clock source**: PCLKB = 60 MHz
00576 * - **Divider**: /32 -> 1.875 MHz
00577 * - **Compare value**: 18749 -> 100.00 Hz
00578 * - **Interrupt priority**: 3/15 (higher than app tasks, lower than motor control)
00579 * - **Tick period**: 10.000 ms (exact, zero drift)
00580 *
00581 * **Hardware configuration sequence**:
00582 * @msc
00583 * Func, CMT_CTRL, CMT0, ICU, CPU;
00584 *
00585 * Func box Func [label="Validate registers"];
00586 * Func => CMT_CTRL [label="Stop: CMSTR0 &= ~0x01"];
00587 * Func => CMT0 [label="Configure: CMCR = 0x00C1"];
00588 * Func => CMT0 [label="Set compare: CMCOR = 4687"];
00589 * Func => CMT0 [label="Reset count: CMCNT = 0"];
00590 * Func => ICU [label="Clear: IR = 0"];
00591 * Func => ICU [label="Priority: IPR = 3"];
00592 * Func => ICU [label="Enable: IER |= bit"];
00593 * Func => CMT_CTRL [label="Start: CMSTR0 |= 0x01"];

00595 * Func => CPU [label="Enable global IRQ: setpsw i"];
00596 * @endmsc
00597 *
00598 *
00599 * @par Return Value Details:
00600 *
00601 * | Return Value | Condition |
00602 * |-----|-----|
00603 * | k_rx_ok | Timer initialized successfully |
00604 * | k_rx_err_invalid_state | cmt_ctrl() or cmt0() returned NULL |
00605 * | k_rx_err_hw_error | CMSTR0 start bit failed to set |
00606 *
00607 * @pre System clocks must be configured (PCLKB = 60 MHz)
00608 * @pre CMT0 must not be in use by another module
00609 * @pre Must be called before tx_kernel_enter()
00610 * @pre Interrupts can be disabled (function enables at end)
00611 *
00612 * @post CMT0 running at 100 Hz, generating periodic interrupts
00613 * @post cmt0_isr() will be called every 10 ms
00614 * @post ThreadX system tick operational
00615 * @post Global interrupts enabled (PSW I-flag set)
00616 *
00617 * @invariant CMT0 compare value = 4687 (100.00 Hz)
00618 * @invariant CMT0 interrupt priority = 3/15
00619 *
00620 * @note **Thread Safety**: Not thread-safe. Must be called during single-threaded
00621 * initialization before ThreadX kernel starts. Do not call from running
00622 * RTOS tasks.
00623 *
00624 * @note **Re-entrancy**: Not reentrant. Calling multiple times without
00625 * timer_stop() is undefined behavior (timer will be reconfigured).
00626 *
00627 * @note **Performance**: Initialization takes ~10 us @ 240 MHz (multiple
00628 * register writes). This is one-time startup cost, not runtime overhead.
00629 *
00630 * @note **Memory**: Zero heap allocation. All configuration is register I/O.
00631 *
00632 * @warning **Call order critical**: Must call timer_init() BEFORE
00633 * tx_kernel_enter(). ThreadX depends on system tick being operational.
00634 * Calling after kernel start causes undefined behavior.
00635 *
00636 * @warning **Clock dependency**: Assumes PCLKB = 60 MHz. If system clock
00637 * configuration changes, k_cmt0_compare_match must be recalculated.
00638 * Incorrect clock frequency causes incorrect tick rate.
00639 *
00640 * @attention **Global interrupt enable**: This function enables global interrupts
00641 * via "setpsw i". If interrupts were intentionally disabled, they
00642 * will be enabled after this call.
00643 *
00644 * @par Example - System Initialization:
00645 * @code
00646 * #include "timer.h"
00647 * #include "tx_api.h"
00648 *
00649 * int main(void)
00650 * {
00651 * // 1. Initialize hardware (clocks, GPIO, etc.)
00652 * hardware_init();
00653 *
00654 * // 2. Initialize system tick BEFORE ThreadX
00655 * rx_err_t err = timer_init();
00656 * if (err != k_rx_ok) {
00657 * rx_log_error("MAIN", "System tick init failed: %d", err);
00658 * while (1) {} // Halt on critical error
00659 * }

```

```

00660 *
00661 * // 3. Define ThreadX application
00662 * tx_application_define(nullptr);
00663 *
00664 * // 4. Start ThreadX kernel (never returns)
00665 * tx_kernel_enter();
00666 * }
00667 * @endcode
00668 *
00669 * @par Example - Error Handling:
00670 * @code
00671 * // Robust initialization with error checking
00672 * rx_err_t err = timer_init();
00673 * switch (err) {
00674 *     case k_rx_ok:
00675 *         rx_log_info("MAIN", "System tick running at 100 Hz");
00676 *         break;
00677 *     case k_rx_err_invalid_state:
00678 *         rx_log_error("MAIN", "Clock not configured - check hardware_init()");
00679 *         return err;
00680 *     case k_rx_err_hw_error:
00681 *         rx_log_error("MAIN", "CMT0 hardware fault");
00682 *         return err;
00683 *     default:
00684 *         rx_log_error("MAIN", "Unexpected error: %d", err);
00685 *         return err;

00779 /**
00780 * @brief Stop CMT0 system tick timer
00781 *
00782 * @details
00783 * Halts the CMT0 timer by clearing the start bit in CMSTR0 register. This
00784 * stops the system tick interrupts, effectively freezing ThreadX scheduling
00785 * and time tracking. Use only during system shutdown or for testing.
00786 *
00787 * **Algorithm steps**:
00788 * 1. Validate CMT_CTRL hardware accessibility
00789 * 2. Check if timer is currently running
00790 * 3. Clear CMSTR0 start bit to stop counter
00791 * 4. Verify timer stopped successfully
00792 *
00793 * **Use cases**:
00794 * - System shutdown sequence
00795 * - Power management (entering low-power mode)
00796 * - Testing and diagnostics
00797 * - Emergency stop during fault condition
00798 *
00799 * @warning Stopping system tick will freeze ThreadX scheduler. All time-based
00800 * operations (tx_thread_sleep, timeouts) will hang. Only call during
00801 * controlled shutdown or with ThreadX suspended.
00802 *
00803 *
00804 * @pre timer_init() must have been called successfully
00805 * @pre CMT0 should be running (otherwise returns k_rx_err_invalid_state)
00806 *
00807 * @post CMT0 timer stopped, CMCNT frozen
00808 * @post No more cmt0_isr() interrupts will occur
00809 * @post ThreadX time tracking frozen (system time no longer increments)
00810 *
00811 * @note **Thread Safety**: Not thread-safe. Should only be called from
00812 * single-threaded shutdown sequence or with ThreadX suspended.
00813 *
00814 * @note **Performance**: Executes in ~1 us @ 240 MHz (register read/write).
00815 *
00816 * @par Example - Controlled Shutdown:
00817 * @code
00818 * // Shutdown sequence
00819 * tx_thread_suspend(&all_app_threads); // Suspend all app threads
00820 *
00821 * rx_err_t err = timer_stop();
00822 * if (err != k_rx_ok) {
00823 *     rx_log_error("SHUTDOWN", "Failed to stop timer: %d", err);
00824 * }
00825 *
00826 * // System is now halted, safe to power down
00827 * @endcode
00828 *
00829 * @see timer_init() Initialize and start timer
00830 * @see timer_get_count() Read current counter value
00831 *
00832 * @since Version 1.0.0
00833 *

00859 /**
00860 * @brief Read current CMT0 counter value
00861 *
00862 * @details
00863 * Reads the current value of CMT0.CMCNT register, which increments from 0 to
00864 * CMCOR (4687) at 468.75 kHz. This provides sub-millisecond timing resolution
00865 * for diagnostics, performance measurement, and jitter analysis.
00866 *
00867 * **Algorithm steps**:
00868 * 1. Validate count pointer is not nullptr
00869 * 2. Validate CMT0 hardware accessibility
00870 * 3. Read CMCNT register (atomic 16-bit read)
00871 * 4. Validate count is within expected range (0-4687)
00872 * 5. Store count value to output parameter
00873 *
00874 * **Counter behavior**:
00875 * - Increments every  $1/(1.875 \text{ MHz}) = 0.533 \text{ us}$ 
00876 * - Resets to 0 when reaching CMCOR (18749)
00877 * - Wraps every 10 ms (one system tick)
00878 * - Can be read at any time without affecting timer operation
00879 *
00880 * **Timing resolution**:
00881 * @f[
00882 * \text{Resolution} = \frac{1}{f_{\text{CMT}}} = \frac{1}{1875000 \text{ Hz}} = 0.533 \text{ us}
00883 * @f]
00884 *
00885 * **Maximum readable value**:
00886 * @f[
00887 * \text{Max count} = \text{CMCOR} = 18749 \approx 10 \text{ ms}
00888 * @f]
00889 *
00890 *
00891 *
00892 * @par Return Value Details:
00893 *
00894 * | Return Value          | Condition                               | *count Value |
00895 * |-----|-----|-----|
00896 * | k_rx_ok               | Normal operation                       | 0 to 18749   |
00897 * | k_rx_err_null_ptr     | count == nullptr                      | Unchanged    |
00898 * | k_rx_err_hw_unmapped  | cmt0() returned NULL                  | Unchanged    |
00899 * | k_rx_err_hw_error     | *count > 4687                        | Invalid value|
00900 *
00901 * @pre timer_init() must have been called successfully
00902 * @pre count pointer must be valid and non-NULL
00903 *
00904 * @post If k_rx_ok: *count contains current CMCNT value (0-4687)
00905 * @post If error: *count unchanged (nullptr) or contains invalid value (hw_error)
00906 * @post Timer operation not affected (read-only access)
00907 *
00908 * @invariant Return value k_rx_ok guarantees *count in [0, 18749]
00909 *
00910 * @note **Thread Safety**: Thread-safe for reading. Multiple threads can call
00911 *       simultaneously. CMCNT is atomic 16-bit register on RX72N. No need for
00912 *       mutual exclusion.
00913 *
00914 * @note **Re-entrancy**: Fully reentrant. Safe to call from ISRs and tasks
00915 *       concurrently. No shared state modified.
00916 *
00917 * @note **Performance**: Executes in ~500 ns @ 240 MHz (single register read).
00918 *       Suitable for high-frequency polling.
00919 *
00920 * @note **Memory**: No heap allocation. Stack usage: ~4 bytes (local variable).

```

```

00921 *
00922 * @warning **Counter wraps**: Counter resets to 0 every 10 ms. For measuring
00923 * intervals longer than 10 ms, use ThreadX system time (tx_time_get)
00924 * instead.
00925 *
00926 * @warning **Race condition**: Counter value is snapshot at time of read. By
00927 * the time caller processes value, hardware counter has advanced.
00928 * Don't assume static value.
00929 *
00930 * @par Example - Basic Usage:
00931 * @code
00932 * uint16_t count;
00933 * rx_err_t err = timer_get_count(&count);
00934 * if (err == k_rx_ok) {
00935 *     // Convert to microseconds: count * 0.533 us
00936 *     float us = count * 0.533f;
00937 *     rx_log_info("TIMER", "Current time in tick: %.1f us", us);
00938 * }
00939 * @endcode
00940 *
00941 * @par Example - Performance Measurement:
00942 * @code
00943 * // Measure execution time of function (sub-tick resolution)
00944 * uint16_t start, end;
00945 * timer_get_count(&start);
00946 *
00947 * // Execute function to measure
00948 * motor_update();
00949 *
00950 * timer_get_count(&end);
00951 *
00952 * // Calculate elapsed time (handle wrap)
00953 * uint16_t elapsed;
00954 * if (end >= start) {
00955 *     elapsed = end - start;
00956 * } else {
00957 *     elapsed = (18749 - start) + end; // Wrapped
00958 * }
00959 *
00960 * float us = elapsed * 0.533f;
00961 * rx_log_info("PERF", "motor_update took %.1f us", us);
00962 * @endcode
00963 *
00964 * @par Example - Jitter Analysis:

Enumerations

- enum `uart_config_constants_t`: `uint32_t` { `k_uart_default_baudrate`, `k_uart_bit_time_delay_cycles` = 125 }
UART configuration constants.
- enum `sci_register_values_t`: `uint8_t` {
`k_sci_scr_disabled` = 0x00 , `k_sci_scr_tx_enabled` = 0x20 , `k_sci_scr_rx_enabled` = 0x10 ,
`k_sci_scr_tsr_enabled` = 0x30 ,
`k_sci_smr_async_8n1` = 0x00 , `k_sci_semr_default` = 0x00 , `k_sci_semr_abcs_bit` ,
`k_sci_scr_rie_bit` = 0x40 }
SCI register control-bit values (SSR flag masks live in `rx72n_sci_regs.h`).

- enum `uart_int_constants_t` : `uint8_t` { `k_uart_int_buffer_size` = 12 , `k_uart_base_10` = 10 }
Integer to string buffer constants.
- enum `uart_hex_constants_t` : `uint8_t` {
`k_uart_hex_max_digits` = 8 , `k_uart_hex_min_digits` = 1 , `k_uart_hex_zero_digits` = 0 ,
`k_uart_hex_nibble_bits` = 4 ,
`k_uart_hex_nibble_mask` = 0x0F }
Hex digit constants.
- enum `brr_constants_t` : `uint16_t` {
`k_brr_divisor_n0` = 32 , `k_brr_divisor_n0_abcs` , `k_brr_multiplier` = 4 , `k_brr_max_value` = 255 ,
`k_brr_min_value` = 0 , `k_brr_formula_offset` = 1 }
BRR calculation constants.
- enum `uart_mstpcrb_constants_t` : `uint32_t` { `k_uart_mstpcrb_bit_set` = 1UL }
MSTPCRB register bit manipulation constants.
- enum `uart_internal_constants_t` : `uint8_t` {
`k_uart_channel_min` = 0 , `k_uart_array_size` = 13 , `k_uart_max_mstpb_channel` = 7 ,
`k_uart_mstpc_channel_min` = 8 ,
`k_uart_mstpc_channel_max` = 11 , `k_uart_pclka_channel_min` = 7 , `k_uart_pclka_channel_max` = 11 , `k_uart_max_channels` = 13 }
Maximum SCI channels (array size, must be enum for compile-time constant).
- enum `uart_validation_limits_t` : `uint32_t` { `k_uart_baudrate_min` , `k_uart_baudrate_max` }
Baud rate validation bounds for `uart_init_channel()` parameter checking.
- enum `uart_timeout_t` : `uint32_t` { `k_uart_tx_timeout` = 100000 , `k_uart_timeout_expired` = 0 , `k_uart_timeout_decrement` = 1 }
UART timeout constants.
- enum `uart_flag_constants_t` : `uint8_t` { `k_uart_flag_clear` = 0 }
UART flag comparison constants.
- enum `uart_buffer_constants_t` : `uint32_t` { `k_uart_max_str_len` = 256 }
UART buffer and string size limits.
- enum `sci_mstpb_bits_t` : `uint8_t` {
`k_sci_mstpb_sci0` = 31 , `k_sci_mstpb_sci1` = 30 , `k_sci_mstpb_sci2` = 29 , `k_sci_mstpb_sci3` = 28 ,
`k_sci_mstpb_sci4` = 27 , `k_sci_mstpb_sci5` = 26 , `k_sci_mstpb_sci6` = 25 , `k_sci_mstpb_sci7` = 24 ,
`k_sci_mstpb_sci12` = 4 }
SCI module stop bit positions in MSTP\rB.
- enum `sci_mstpc_bits_t` : `uint8_t` { `k_sci_mstpc_sci8` = 27 , `k_sci_mstpc_sci9` = 26 ,
`k_sci_mstpc_sci10` = 25 , `k_sci_mstpc_sci11` = 24 }
SCI module stop bit positions in MSTP\rC.
- enum `uart_debug_pins_t` : `uint16_t` { `k_uart_debug_tx_gpio` = `k_rx_pb_7` , `k_uart_debug_rx_gpio` = `k_rx_pb_6` }
Debug UART pins (SCI9 on RX72N).
- enum `uart_gpio_constants_t` : `uint8_t` { `k_uart_gpio_bit_set` = 1 }
GPIO register bit manipulation constants for UART pin configuration.
- enum `sci9_rx_ring_consts_t` : `uint16_t` { `k_sci9_rx_ring_size` , `k_sci9_rx_ring_mask` = `k_sci9_rx_ring_size` - 1U , `k_sci9_rx_ring_priority` = 3U }

Functions

- static `uint8_t` `internal_calculate_brr` (const `uint32_t` baudrate, const `uint32_t` pclk_hz, const bool abcs)
Calculate the 8-bit BRR register value for a target baud rate.
- static void `internal_clear_errors` (volatile `rx_sci_regs_t` *sci)

- Clear receive error flags in the SCI Serial Status Register (SSR).
- static int8_t [internal_get_mstpb_bit](#) (const uint8_t channel)
 - Return the MSTP\B bit position for a channel, or -1 for MSTP\RC channels.
- static rx_err_t [internal_enable_sci_clock](#) (const uint8_t channel)
 - Enable the peripheral clock for an SCI channel.
- static rx_err_t [internal_configure_uart_pins](#) (const rx_port_pin_t tx_gpio, rx_port_pin_t rx_gpio)
 - Configure the GPIO and MPC pin-mux settings for a UART TX/RX pin pair.
- static rx_err_t [internal_uart_validate_init](#) (const [uart_channel_config_t](#) *const config, volatile [rx_sci_regs_t](#) **const sci_out)
 - Initialize UART channel with specified configuration.
- static uint32_t [internal_uart_select_pclk](#) (const [uart_channel_t](#) channel)
 - Resolve the peripheral clock frequency for a given SCI channel.
- static void [internal_uart_program_baud](#) (volatile [rx_sci_regs_t](#) *const sci, const [uart_channel_t](#) channel, const uint32_t baudrate)
 - Program SMR/SEMR/BRR for the requested channel and baud.
- static void [internal_uart_enable_sci9_rx_isr](#) (volatile [rx_sci_regs_t](#) *const sci)
 - Switch SCI9 to interrupt-driven RX mode.
- rx_err_t [uart_init_channel](#) (const [uart_channel_config_t](#) *config)
 - Initialize SCI channel for UART communication.
- rx_err_t [uart_deinit_channel](#) (const [uart_channel_t](#) channel)
 - Deinitialize UART channel and disable TX/RX.
- rx_err_t [uart_putc_channel](#) (const [uart_channel_t](#) channel, const char data)
 - Transmit single character on UART channel.
- rx_err_t [uart_puts_channel](#) (const [uart_channel_t](#) channel, const char *str)
 - Transmit null-terminated string on UART channel with newline conversion.
- rx_err_t [uart_write_channel](#) (const [uart_channel_t](#) channel, const uint8_t *data, uint16_t length)
 - Write binary data to UART channel without newline conversion.
- rx_err_t [uart_getc_channel](#) (const [uart_channel_t](#) channel, char *data)
 - Receive single character from UART channel (non-blocking).
- rx_err_t [uart_read_channel](#) (const [uart_channel_t](#) channel, uint8_t *data, uint16_t length, uint16_t *bytes_read)
 - Read available bytes from UART channel (non-blocking).
- rx_err_t [uart_rx_available](#) (const [uart_channel_t](#) channel, bool *available)
 - Check if receive data is available on UART channel.
- rx_err_t [uart_clear_rx_errors](#) ([uart_channel_t](#) channel)
 - Clear sticky receive error flags (ORER/FER/PER) on a UART channel.
- void [INT_SCI9_RXI9](#) (void)
 - SCI9 receive-data-full interrupt (vector 102).
- rx_err_t [uart_debug_init](#) (void)
 - Initialize default debug UART channel (SCI9 at 115200 baud).
- void [uart_debug_putc](#) (const char data)
 - Transmit single character on debug UART (SCI9).
- void [uart_debug_puts](#) (const char *str)
 - Transmit null-terminated string on debug UART with newline conversion.
- void [uart_debug_putint](#) (const int32_t value)
 - Transmit signed 32-bit integer as decimal string on debug UART.
- void [uart_debug_puthex](#) (const uint32_t value, uint8_t digits)
 - Transmit 32-bit unsigned integer as hexadecimal string on debug UART.

Variables

- static bool `s_channel_initialized` [`k_uart_array_size`] = {false}
Per-channel initialization state.
- static volatile uint8_t `s_sci9_rx_ring` [`k_sci9_rx_ring_size`]
- static volatile uint16_t `s_sci9_rx_head` = 0U
- static volatile uint16_t `s_sci9_rx_tail` = 0U

8.139.1 Detailed Description

Multi-Channel UART Driver for RX72N SCI Peripherals.

8.139.1.1 Overview

Production-quality UART driver for RX72N Serial Communication Interface (SCI) peripherals. Provides synchronous TX and RX functionality across 13 SCI channels (SCI0-SCI12) with configurable baud rates, automatic newline conversion, and comprehensive error handling.

8.139.1.2 Architecture

8.139.1.3 Hardware Details

Hardware Requirements:

Component	Requirement	Notes
MCU	Renesas RX72N	SCI peripheral required
Channels	SCI0-SCI12	13 channels total
Clock	PCLKB (SCI0-6,12) / PCLKA (SCI7-11)	Per-channel BRR clock
TX Pin	Port pin configured as output	Requires MPC configuration
RX Pin	Port pin configured as input	Requires MPC configuration
USB Bridge	CY7C65213 (default)	For SCI9 debug channel

Default Debug Configuration (SCI9):

Parameter	Value	Notes
Channel	SCI9	Connected to USB-UART bridge
TX Pin	PB7 (TXD9)	Output, peripheral mode
RX Pin	PB6 (RXD9)	Input, peripheral mode
Baud Rate	115200 bps	Standard debug speed
Data Bits	8	Fixed
Parity	None	Fixed
Stop Bits	1	Fixed

8.139.1.4 Baud Rate Calculation

The SCI baud rate formula for n=0 (CKS=00, PCLK/1):

$$\text{BRR} = \frac{\text{PCLK}}{32 \times B} - 1$$

f_PCLK depends on the channel group (manual section 5 I/O register table):

- SCI0-SCI6, SCI12 (SCIj/SCIh): PCLKB (k_pclkb_hz, 60 MHz)
- SCI7-SCI11 (SCIi, extended 0x000D0xxx): PCLKA (k_pclka_hz, 120 MHz)

Note: [rx72n_clock.h](#) is authoritative for PCLK frequencies; trust the header over any older bench note. PCLKB = 60 MHz on this platform.

Supported Baud Rates (at PCLKB = 60 MHz, for SCI0-SCI6/SCI12):

Baud Rate	BRR	Actual Rate	Error
9600	194	9615	+0.16%
19200	96	19231	+0.16%
38400	47	38462	+0.16%
57600	31	58594	+1.73%
115200	15	117188	+1.73%
230400	7	234375	+1.73%
460800	3	468750	+1.73%
921600	1	937500	+1.73%

8.139.1.5 Performance Characteristics

Operation	Execution Time	Stack Usage	Notes
uart_init_channel	~50 us	48 bytes	Includes MPC configuration
uart_putc_channel	~90 us @ 115200	16 bytes	Includes wait for TDRE
uart_puts_channel	~90 us/char	24 bytes	With LF->\r\n conversion
uart_getc_channel	~5 us	16 bytes	Non-blocking if no data
uart_debug_init	~50 us	64 bytes	Wrapper for SCI9

Memory Footprint:

- Code size: ~2 KB (all functions)
- Static data: 13 bytes (s_channel_initialized array)
- Stack usage: < 64 bytes (deepest call)
- Heap usage: 0 bytes (zero dynamic allocation)

8.139.1.6 Thread Safety

Function	Thread Safe?	Notes
uart_init_channel	[FAIL] No	Call once per channel during init
uart_deinit_channel	[FAIL] No	Call once during shutdown
uart_putc_channel	[WARN] Partial	Safe if different channels
uart_puts_channel	[WARN] Partial	Safe if different channels
uart_getc_channel	[WARN] Partial	Safe if different channels
uart_debug↵_*	[WARN] Partial	All use same channel (SCI9)

Note: Multiple threads can safely use different UART channels simultaneously. For shared channel access, use external mutex protection.

Module Dependencies:

This module depends on:

- [hardware.h](#) - Hardware configuration and channel constants
- [rx72n_clock.h](#) - PCLKB frequency definition
- [rx72n_regs.h](#) - SCI register definitions
- [rx_mpc.h](#) - Pin mux configuration
- [rx_port_utils.h](#) - GPIO port utilities
- [rx_register_protection.h](#) - PR\r register protection

This module is used by:

- [rx_log.c](#) - Logging subsystem output
- [main.c](#) - Debug output during initialization
- [comm_task.c](#) - Communication task debug messages

NASA Power of 10 Compliance:

Rule	Status	Implementation
1. Simple control flow	↔ [OK]↔	No goto/setjmp/recursion
2. Fixed loop bounds	↔ [OK]↔	All loops use k_uart_max_str_len limit
3. No dynamic allocation	↔ [OK]↔	Zero malloc/free, static buffers only
4. Small functions	↔ [OK]↔	All functions < 60 lines
5. Assertions (>=2/func)	↔ [OK]↔	Parameter validation + state checks
6. Narrow scope	↔ [OK]↔	Static file-scope state, local variables
7. Check return values	↔ [OK]↔	All rx_err_t returns propagated

Rule	Status	Implementation
8. Limited preprocessor	↔ [OK]↔	C23 typed enums only
9. Pointer restrictions	↔ [OK]↔	Single-level pointers, no arithmetic
10. Compiler warnings	↔ [OK]↔	-Wall -Wextra -Werror clean

SOLID Principles:

Single Responsibility (S):

- This module handles ONLY UART communication
- Separate from higher-level logging (rx_log.c)
- Separate from protocol parsing (rx_frame.c)

Open/Closed (O):

- New baud rates supported without code changes
- New channels added via configuration structure
- Pin assignments configurable per-channel

Liskov Substitution (L):

- All channel functions accept any valid channel
- Consistent rx_err_t return semantics
- Debug functions are simple wrappers

Interface Segregation (I):

- Separate init/deinit from TX/RX operations
- Debug functions provide simplified interface
- Channel functions provide full control

Dependency Inversion (D):

- Uses abstract rx_port_pin_t for pin specification
- Uses rx_mpc module for pin configuration
- Uses rx_err_t for standardized error handling

8.139.2 Enumeration Type Documentation

8.139.2.1 brr`constants` t

enum [brr_constants_t](#) : uint16_t

BRR calculation constants.

Enumerator

k_brr_divisor_n0	Divisor for n=0, ABCS=0 (default 16-cycle base): $64 * 2^{(2n-1)} = 32$
k_brr_divisor_n0_abcs	Divisor for n=0, ABCS=1 (8-cycle base): halves the divisor, HUM 34.2.12 ↵
k_brr_multiplier	Multiplier per CKS increment (2^2)
k_brr_max_value	Maximum BRR register value
k_brr_min_value	Minimum BRR register value
k_brr_formula_offset	BRR formula subtract-1 offset: $BRR = (PCLK / (div * B)) - 1$

Definition at line 271 of file [uart.c](#).

```
00271     : uint16_t {
00272 k_brr_divisor_n0 = 32, /**< Divisor for n=0, ABCS=0 (default 16-cycle base): 64 * 2^(2n-1) = 32 */
00273 k_brr_divisor_n0_abcs =
00274     16, /**< Divisor for n=0, ABCS=1 (8-cycle base): halves the divisor, HUM 34.2.12 */
00275 k_brr_multiplier     = 4, /**< Multiplier per CKS increment (2^2) */
00276 k_brr_max_value      = 255, /**< Maximum BRR register value */
00277 k_brr_min_value      = 0, /**< Minimum BRR register value */
00278 k_brr_formula_offset = 1, /**< BRR formula subtract-1 offset: BRR = (PCLK/(div*B)) - 1 */
00279 } brr_constants_t;
```

8.139.2.2 sci9'rx'ring'consts't

```
enum sci9\_rx\_ring\_consts\_t : uint16_t
```

Enumerator

k_sci9_rx_ring_size	Power-of-2 mask-friendly size; covers 4.4 ms of 115200-baud traffic
k_sci9_rx_ring_mask	
k_sci9_rxi9_priority	IPR[102]: lower than motor ctrl, higher than CMT tick

Definition at line [462](#) of file [uart.c](#).

```
00462      : uint16_t {
00463  k_sci9_rx_ring_size =
00464      512U, /**< Power-of-2 mask-friendly size; covers 4.4 ms of 115200-baud traffic */
00465  k_sci9_rx_ring_mask = k_sci9_rx_ring_size - 1U,
00466  k_sci9_rxi9_priority = 3U, /**< IPR[102]: lower than motor ctrl, higher than CMT tick */
00467 } sci9_rx_ring_consts_t;
```

8.139.2.3 sci'mstpb'bits't

```
enum sci\_mstpb\_bits\_t : uint8_t
```

SCI module stop bit positions in MSTP\rB.

SCI0-SCI7 occupy contiguous bits 31-24 (MSTPB31 down to MSTPB24). SCI12 (SCIh module) is a non-contiguous outlier at MSTPB4. SCI8-SCI11 live in MSTP\rC, not here – see [sci_mstpc_bits_t](#).

Manual: section 11.2.3 MSTP\rB, page 408.

Enumerator

k_sci_mstpb_sci0	SCI0 module stop bit in MSTPCRB (MSTPB31)
k_sci_mstpb_sci1	SCI1 module stop bit in MSTPCRB (MSTPB30)
k_sci_mstpb_sci2	SCI2 module stop bit in MSTPCRB (MSTPB29)
k_sci_mstpb_sci3	SCI3 module stop bit in MSTPCRB (MSTPB28)
k_sci_mstpb_sci4	SCI4 module stop bit in MSTPCRB (MSTPB27)
k_sci_mstpb_sci5	SCI5 module stop bit in MSTPCRB (MSTPB26)
k_sci_mstpb_sci6	SCI6 module stop bit in MSTPCRB (MSTPB25)
k_sci_mstpb_sci7	SCI7 module stop bit in MSTPCRB (MSTPB24)
k_sci_mstpb_sci12	SCI12 (SCIh) module stop bit in MSTPCRB (MSTPB4)

Definition at line [373](#) of file [uart.c](#).

```
00373      : uint8_t {
00374  k_sci_mstpb_sci0 = 31, /**< SCI0 module stop bit in MSTPCRB (MSTPB31) */
00375  k_sci_mstpb_sci1 = 30, /**< SCI1 module stop bit in MSTPCRB (MSTPB30) */
00376  k_sci_mstpb_sci2 = 29, /**< SCI2 module stop bit in MSTPCRB (MSTPB29) */
00377  k_sci_mstpb_sci3 = 28, /**< SCI3 module stop bit in MSTPCRB (MSTPB28) */
00378  k_sci_mstpb_sci4 = 27, /**< SCI4 module stop bit in MSTPCRB (MSTPB27) */
00379  k_sci_mstpb_sci5 = 26, /**< SCI5 module stop bit in MSTPCRB (MSTPB26) */
00380  k_sci_mstpb_sci6 = 25, /**< SCI6 module stop bit in MSTPCRB (MSTPB25) */
00381  k_sci_mstpb_sci7 = 24, /**< SCI7 module stop bit in MSTPCRB (MSTPB24) */
00382  k_sci_mstpb_sci12 = 4, /**< SCI12 (SCIh) module stop bit in MSTPCRB (MSTPB4) */
00383 } sci_mstpb_bits_t;
```

8.139.2.4 sci_mstpc_bits_t

```
enum sci_mstpc_bits_t : uint8_t
```

SCI module stop bit positions in MSTP\RC.

SCI8-SCI11 (SCIi module, extended peripheral region 0x000D0000) are controlled by MSTP\RC, NOT MSTP\RB. Clearing the corresponding bit releases the channel from the module-stop state.

Manual: section 11.2.4 MSTP\RC, page 410.

Enumerator

k_sci_mstpc_sci8	SCI8 module stop bit in MSTPCRC (MSTPC27)
k_sci_mstpc_sci9	SCI9 module stop bit in MSTPCRC (MSTPC26)
k_sci_mstpc_sci10	SCI10 module stop bit in MSTPCRC (MSTPC25)
k_sci_mstpc_sci11	SCI11 module stop bit in MSTPCRC (MSTPC24)

Definition at line 394 of file [uart.c](#).

```
00394     : uint8_t {
00395     k_sci_mstpc_sci8 = 27, /**< SCI8 module stop bit in MSTPCRC (MSTPC27) */
00396     k_sci_mstpc_sci9 = 26, /**< SCI9 module stop bit in MSTPCRC (MSTPC26) */
00397     k_sci_mstpc_sci10 = 25, /**< SCI10 module stop bit in MSTPCRC (MSTPC25) */
00398     k_sci_mstpc_sci11 = 24, /**< SCI11 module stop bit in MSTPCRC (MSTPC24) */
00399 } sci_mstpc_bits_t;
```

8.139.2.5 sci_register_values_t

```
enum sci_register_values_t : uint8_t
```

SCI register control-bit values (SSR flag masks live in [rx72n_sci_regs.h](#)).

Enumerator

k_sci_scr_disabled	SCR: All functions disabled
k_sci_scr_tx_enabled	SCR: Transmit enabled (TE=1)
k_sci_scr_rx_enabled	SCR: Receive enabled (RE=1)
k_sci_scr_txrx_enabled	SCR: TX + RX enabled (TE=1, RE=1)
k_sci_smr_async_8n1	SMR: Async mode, 8 data bits, no parity, 1 stop bit, PCLK/1
k_sci_semr_default	SEMR: Default extended mode (ABCS=0, 16-cycle base)
k_sci_semr_abcs_bit	SEMR.ABCS: 1=8-cycle base clock (halves BRR divisor, HUM 34.2.12)
k_sci_scr_rie_bit	SCR.RIE: receive interrupt enable (HUM 34.2.5)

Definition at line 243 of file [uart.c](#).

```
00243     : uint8_t {
00244     k_sci_scr_disabled = 0x00, /**< SCR: All functions disabled */
00245     k_sci_scr_tx_enabled = 0x20, /**< SCR: Transmit enabled (TE=1) */
00246     k_sci_scr_rx_enabled = 0x10, /**< SCR: Receive enabled (RE=1) */

00248     k_sci_smr_async_8n1 = 0x00, /**< SMR: Async mode, 8 data bits, no parity, 1 stop bit, PCLK/1 */
00249     k_sci_semr_default = 0x00, /**< SEMR: Default extended mode (ABCS=0, 16-cycle base) */
00250     k_sci_semr_abcs_bit =
00251     0x10, /**< SEMR.ABCS: 1=8-cycle base clock (halves BRR divisor, HUM 34.2.12) */
00252     k_sci_scr_rie_bit = 0x40, /**< SCR.RIE: receive interrupt enable (HUM 34.2.5) */
00253 } sci_register_values_t;
```

8.139.2.6 `uart`buffer`constants`t`

```
enum uart\_buffer\_constants\_t : uint32_t
```

UART buffer and string size limits.

Enumerator

<code>k_uart_max_str_len</code>	Maximum string length for <code>uart_puts_channel</code>
---------------------------------	--

Definition at line 360 of file [uart.c](#).

```
00360      : uint32_t {
00361  k_uart_max_str_len = 256, /**< Maximum string length for uart_puts_channel */
00362 } uart_buffer_constants_t;
```

8.139.2.7 `uart`config`constants`t`

```
enum uart\_config\_constants\_t : uint32_t
```

UART configuration constants.

Enumerator

<code>k_uart_default_baudrate</code>	Default baud rate: 921600 bps. Max standard rate that hits <2%% error on SCI9 with PCLKA=120 MHz. Formula (ABCS=0/CKS=00): $BRR = PCLKA / (32 * B) - 1$. $120e6 / (32 * 921600) - 1 = 4.07 \rightarrow BRR = 3$ Actual rate = $120e6 / (32 * (3 + 1)) = 937500$ bps Error vs 921600 = $(937500 - 921600) / 921600 = +1.72\%$ (well within ~3%% UART tolerance) Well within the CY7C65213 USB-UART bridge's 3 Mbps ceiling.
<code>k_uart_bit_time_delay_cycles</code>	~1.09us at 921600 bps, ~260 cycles @240 MHz

Definition at line 225 of file [uart.c](#).

```
00225      : uint32_t {
00226  /**
00227   * @brief Default baud rate: 921600 bps
00228   *
00229   * Max standard rate that hits <2%% error on SCI9 with PCLKA=120 MHz.
00230   * Formula (ABCS=0/CKS=00):  $BRR = PCLKA / (32 * B) - 1$ .
00231   *  $120e6 / (32 * 921600) - 1 = 4.07 \rightarrow BRR = 3$ 
00232   * Actual rate =  $120e6 / (32 * (3 + 1)) = 937500$  bps
00233   * Error vs 921600 =  $(937500 - 921600) / 921600 = +1.72\%$  (well within ~3%% UART tolerance)
00234   *
00235   * Well within the CY7C65213 USB-UART bridge's 3 Mbps ceiling.
00236   */
00237  k_uart_default_baudrate =
00238    115200, /** matches motors_rtos/HIL-tests; 921600 at PCLKB=60 MHz has 1.7% BRR rounding error */
00239  k_uart_bit_time_delay_cycles = 125, /**< ~1.09us at 921600 bps, ~260 cycles @240 MHz */
00240 } uart_config_constants_t;
```

8.139.2.8 `uart`debug`pins`t`

```
enum uart\_debug\_pins\_t : uint16_t
```

Debug UART pins (SCI9 on RX72N).

Enumerator

k_uart_debug_tx_gpio	PB7 = TXD9
k_uart_debug_rx_gpio	PB6 = RXD9

Definition at line 402 of file [uart.c](#).

```
00402      : uint16_t {
00403  k_uart_debug_tx_gpio = k_rx_pb_7, /**< PB7 = TXD9 */
00404  k_uart_debug_rx_gpio = k_rx_pb_6, /**< PB6 = RXD9 */
00405 } uart_debug_pins_t;
```

8.139.2.9 uart`flag`constants`t

```
enum uart\_flag\_constants\_t : uint8_t
```

UART flag comparison constants.

Enumerator

k_uart_flag_clear	Flag bit is not set (comparison result)
-------------------	---

Definition at line 355 of file [uart.c](#).

```
00355      : uint8_t {
00356  k_uart_flag_clear = 0, /**< Flag bit is not set (comparison result) */
00357 } uart_flag_constants_t;
```

8.139.2.10 uart`gpio`constants`t

```
enum uart\_gpio\_constants\_t : uint8_t
```

GPIO register bit manipulation constants for UART pin configuration.

Provides the single-bit seed value used when constructing per-pin bitmasks for the PDR (Port Direction Register) and PMR (Port Mode Register) during UART TX/RX pin setup. A bit mask for a specific pin is formed by shifting this value left by the pin index obtained from `rx_pin_from_pin()`.

Invariant

k_uart_gpio_bit_set must equal 1 so that left-shifting by a pin index produces an isolated single-bit mask.

Example:

```
// Build the TX pin mask and set the direction bit
const uint8_t tx_pin      = rx_pin_from_pin(tx_gpio);
const uint8_t tx_pin_mask = (uint8_t)(k_uart_gpio_bit_set « tx_pin);
tx_port_base->pdr |= tx_pin_mask; // Set output direction
tx_port_base->pmr |= tx_pin_mask; // Switch to peripheral mode
```

See also

00352 } uart_timeout_t;
```

8.139.2.16 `uart_validation_limits_t`

```
enum uart\_validation\_limits\_t : uint32_t
```

Baud rate validation bounds for [uart_init_channel\(\)](#) parameter checking.

Defines the closed interval [`k_uart_baudrate_min`, `k_uart_baudrate_max`] that every requested baud rate must satisfy before the driver attempts to program the BRR register.

The maximum is derived directly from the BRR formula for `n=0` (`CKS=00`):

$$\text{BRR} = \frac{\text{PCLKB}}{32 \times B} - 1 \geq 0 \implies B \leq \frac{\text{PCLKB}}{32}$$

A BRR of 0 corresponds to the fastest achievable baud rate at the current PCLKB frequency, so requesting anything higher would underflow the register.

The minimum is 1 bps, which prevents a divide-by-zero in the BRR formula. In practice, any baud rate below ~9600 is impractical on a 60 MHz PCLKB, but the lower bound is kept permissive to avoid false negatives during testing.

Invariant

`k_uart_baudrate_min` must be > 0 to prevent division by zero in [internal_calculate_brr\(\)](#).

`k_uart_baudrate_max` must equal `k_pclkb_hz / k_brr_divisor_n0` so that the computed BRR is always ≥ 0 (i.e., no register underflow).

Example:

```
// Validation performed inside uart_init_channel()
if ((config->baudrate < k_uart_baudrate_min) ||
    (config->baudrate > k_uart_baudrate_max)) {
    return k_rx_err_invalid_arg;
}
```

```

8.139.3 Function Documentation

8.139.3.1 INT`SCI9`RXI9()

```
void INT_SCI9_RXI9 (
    void )
```

SCI9 receive-data-full interrupt (vector 102).

Fires when a byte lands in SCI9.RDR (RDRF rising edge). Reads the byte, clears RDRF by writing-0 after a read of SSR per HUM 34.2.8, and pushes the byte into s_sci9_rx_ring. ORER (overrun error) is checked and cleared so a dropped byte doesn't wedge the peripheral; the drop counter is incremented so telemetry can surface it.

ISR execution time: ~200 ns at 240 MHz (8 register ops + ring push). Ring capacity: k_sci9_rx_↵ ring_size = 512 bytes = 4.4 ms of 115200 baud which comfortably covers the ~10 ms comm_task poll period worst case.

Registered at relocatable-vector-table slot 102 via the \$tableentry\$102\$.rvecrors symbol below. Without that symbol the linker script (src/boot/linker_script_rvecrors.inc) falls through to \$tableentry\$default\$.rvecrors (0xFFFFFFFF), and the interrupt is effectively disabled even with IER↵ [12].bit6 set.

attribute((interrupt)) makes GCC generate the RTE / full register save+restore for the ISR body; the \$tableentry alias just places the function at the right vector slot.

Here is the call graph for this function:

8.139.3.2 internal`calculate`brr()

```
uint8_t internal_calculate_brr (  
    const uint32_t baudrate,  
    const uint32_t pclk_hz,  
    const bool abcs) [static]
```

Calculate the 8-bit BRR register value for a target baud rate.

Computes the value to be written to the SCI Bit Rate Register (BRR) so that the SCI peripheral generates the requested baud rate from PCLKB. The general RX72N SCI baud rate formula for asynchronous mode is:

$$\text{BRR} = \frac{\text{PCLKB}}{64 \times 2^{2n-1} \times B} - 1$$

This driver always uses $n=0$ (CKS bits = 0b00, clock source = PCLK/1), which simplifies to:

$$\text{BRR} = \frac{\text{PCLK}}{32 \times B} - 1$$

The caller supplies the correct PCLK frequency for the target channel:

- SCI0-SCI6, SCI12 (SCIj/SCIh, standard region): use `k_pclkb_hz`
- SCI7-SCI11 (SCIi, extended region 0x00D0xxx): use `k_pclka_hz`

This distinction matters when $\text{PCLKA} \neq \text{PCLKB}$. [rx72n_clock.h](#) is the authoritative source for PCLK frequencies (`k_pclka_hz`, `k_pclkb_hz`, etc.); trust the header over any older bench note.

Algorithm steps:

1. Guard against `baudrate == 0` (return `k_brr_max_value` as a safe sentinel).
2. Guard against `baudrate > pclk_hz/32` (return `k_brr_min_value`).
3. Compute `divisor_result = pclk_hz / (32 * B)` using integer arithmetic.
4. Guard against `divisor_result <= 1` to prevent underflow from the -1 offset.
5. Compute `BRR = divisor_result - 1`.
6. Clamp the result to `k_brr_max_value` (255) if the integer exceeds the 8-bit range (indicates a baud rate too slow for this clock).
7. Return the clamped 8-bit result.

Precondition

baudrate validated by caller; `pclk_hz` must be non-zero
`k_brr_divisor_n0` must be non-zero compile-time constant

Postcondition

Return value is always in `[0, 255]`
 Caller must write the returned value to `sci->brr` before enabling TX/RX

Note

Stateless pure function; safe to call from any context including ISR
 Always uses $n=0$ (CKS=00); support for $n=1..3$ is not implemented

Example:

```
// SCI9 uses PCLKA (SCIi extended region), ABCS=1 for baud accuracy
sci->brr = internal_calculate_brr(115200U, k_pclka_hz, true);
```

Here is the caller graph for this function:

8.139.3.3 internal_clear_errors()

```
void internal_clear_errors (
    volatile rx_sci_regs_t * sci) [static]
```

Clear receive error flags in the SCI Serial Status Register (SSR).

Reads the SSR register and writes it back with the three receive error flag bits masked out, which clears any pending ORER (Overrun Error), FER (Framing Error), and PER (Parity Error) conditions on the SCI channel.

The RX72N SCI peripheral requires a read-modify-write sequence to clear error flags: the hardware only allows clearing a flag by writing 0 to it while keeping the rest of the register unchanged. Writing 1 to an already-set flag has no effect (the write is ignored).

Algorithm steps:

1. Guard: return immediately if sci is nullptr (NASA Power of 10 Rule 5).
2. Read the current value of sci->ssr into a local volatile variable.
3. Cast-to-void the read result to suppress the unused-variable warning while still ensuring the volatile read is not optimised away.
4. Write sci->ssr = (ssr & ~k_sci_ssr_error_mask) to clear bits [5:3] (ORER, FER, PER) while preserving all other SSR bits.

Error flag bit positions in SSR:

Bit	Flag	Description
5	ORER	Overflow Error - new data arrived before previous data was read
4	FER	Framing Error - no valid stop bit detected
3	PER	Parity Error - parity mismatch (unused in 8N1 mode)

Precondition

sci must point to a valid, hardware-mapped `rx_sci_regs_t` register block

The SCI module clock must be enabled (MSTP\RB bit cleared) before any SSR access; undefined behaviour otherwise

Postcondition

ORER, FER, and PER bits in sci->ssr are cleared (written to 0)

All other SSR bits (TDRE, RDRF, TEND, MPB, MPBT) are preserved

Note

This function is intentionally void-returning; the caller (`uart_getc_channel`) checks for errors before calling and does not need a return code

The intermediate volatile read prevents the compiler from merging the read and write into a single store, which would miss the read requirement

Thread Safety:

Not thread-safe. SSR is a read-modify-write target; concurrent access from two threads on the same channel can corrupt flag state. External mutex protection is required if multiple threads share a channel.

Performance:

- Execution time: ~3 cycles (volatile read + mask + volatile write)
- Stack usage: 4 bytes (one volatile `uint8_t` local)

Example:

```
volatile rx_sci_regs_t* sci = sci_get_channel(k_uart_channel_9);
if (sci != nullptr) {
    // Clear any stale error flags before reading receive data
    internal_clear_errors(sci);
    const char data = (char)sci->rdr;
}
```

Here is the caller graph for this function:

8.139.3.4 internal`configure`uart`pins()

```
rx_err_t internal_configure_uart_pins (
    const rx_port_pin_t tx_gpio,
    rx_port_pin_t rx_gpio) [static]
```

Configure the GPIO and MPC pin-mux settings for a UART TX/RX pin pair.

Prepares the two GPIO pins required for SCI UART operation by programming the Multi-Function Pin Controller (MPC) and the Port Direction/Mode registers in the correct order. The RX72N hardware requires that:

- MPC is configured before switching a pin to peripheral mode (PMR)
- TX pin is driven as an output; RX pin is configured as an input
- Both pins are switched to peripheral mode (PMR bit = 1) last

Algorithm steps:

1. Extract the port number and pin number from each `rx_port_pin_t` using `rx_port_from_pin()` and `rx_pin_from_pin()`.
2. Validate that both pin numbers are $\leq k_rx_pin_max$ (7); return `k_rx_err_invalid_arg` if out of range. (Lower-bound check is omitted because pin numbers are `uint8_t` and `k_rx_pin_min == 0`, which would trigger -Wtype-limits.)
3. Obtain volatile port register base pointers via `rx_port_get_base()`; return `k_rx_err_invalid_arg` if either is `nullptr` (invalid port number).
4. Call `rx_mpc_set_sci(tx_gpio)` to set the TX pin's PFS register to the SCI TXD function; propagate any error immediately.
5. Call `rx_mpc_set_sci(rx_gpio)` to set the RX pin's PFS register to the SCI RXD function; propagate any error immediately.
6. Build per-pin bitmasks (`k_uart_gpio_bit_set << pin_number`).
7. Set PDR bit for TX pin (output direction) and PMR bit for TX pin (peripheral mode).
8. Clear PDR bit for RX pin (input direction) and set PMR bit for RX pin (peripheral mode).
9. Return `k_rx_ok`.

MPC write protection: `rx_mpc_set_sci()` internally handles the PFSWE unlock/lock sequence, so this function does not need to touch the PFSWE bit directly.

Pin direction and mode summary:

Pin	PDR (direction)	PMR (mode)
TX	1 (output)	1 (peripheral)
RX	0 (input)	1 (peripheral)

Precondition

`tx_gpio` and `rx_gpio` must correspond to physically valid RX72N port pins

The SCI module clock must already be enabled (MSTP\RB bit cleared) so that the SCI TXD/RXD MPC function codes are accepted

Postcondition

TX pin: PDR bit set (output), PMR bit set (peripheral function)

RX pin: PDR bit cleared (input), PMR bit set (peripheral function)

Both pins' PFS registers configured for SCI TX/RX function via MPC

Note

Pin validation only checks upper bound (`>k_rx_pin_max`); lower bound (0) is omitted to avoid the `-Wtype-limits` compiler warning triggered by comparing an unsigned type to 0

Warning

Passing the same pin for both TX and RX produces undefined hardware behaviour; no duplicate-pin check is performed

Thread Safety:

Not thread-safe. PDR/PMR are read-modify-write targets shared with all GPIO operations on the same port. Call only during single-threaded initialization.

Performance:

- Execution time: ~10 us (dominated by two `rx_mpc_set_sci()` calls)
- Stack usage: 32 bytes (four `uint8_t` locals + two pointer locals)

Example:

```
// Configure SCI9 default debug pins (PB7=TX, PB6=RX)
rx_err_t err = internal_configure_uart_pins(
    (rx_port_pin_t)k_uart_debug_tx_gpio,
    (rx_port_pin_t)k_uart_debug_rx_gpio);
if (err != k_rx_ok) {
    return err; // Invalid pin specification or MPC error
}
```

8.139.3.5 internal`enable`sci`clock()

```
rx_err_t internal_enable_sci_clock (
    const uint8_t channel) [static]
```

Enable the peripheral clock for an SCI channel.

Clears the module-stop bit for the given SCI channel so its clock runs. Different channel groups use different control registers (manual 11.2.3/11.2.4):

Channels	Register	Bits
SCI0-SCI7	MSTP\`rB	31-24
SCI8-SCI11	MSTP\`rC	27-24
SCI12	MSTP\`rB	4

Both MSTP\`rB and MSTP\`rC are PR\`r-protected; this function performs the required unlock/modify/↔lock sequence for whichever register applies.

Precondition

channel validated by [uart_init_channel\(\)](#) to be in [0, 12]
PR\`r not already unlocked by another context

Postcondition

Module-stop bit cleared; SCI clock gate open
PR\`r returned to locked state

Warning

Not thread-safe; unlock/modify/lock must be atomic

Since

8.139.3.6 internal_get_mstpb_bit()

```
int8_t internal_get_mstpb_bit (
    const uint8_t channel) [static]
```

Return the MSTP\RB bit position for a channel, or -1 for MSTP\RC channels.

Per manual section 11.2.3/11.2.4:

- SCI0-SCI7: MSTP\RB bits 31-24 (contiguous, descending)
- SCI8-SCI11: MSTP\RC bits 27-24 – returns -1, caller uses MSTP\RC
- SCI12 (SCIh): MSTP\RB bit 4 (non-contiguous outlier)

Bit position table:

Channel	Register	Bit	Enum constant
SCI0	MSTP\RB	31	k_sci_mstpb_sci0
SCI1	MSTP\RB	30	k_sci_mstpb_sci1
...	MSTP\RB	...	...
SCI7	MSTP\RB	24	k_sci_mstpb_sci7
SCI8	MSTP\RC	27	(returns -1)
SCI9	MSTP\RC	26	(returns -1)
SCI10	MSTP\RC	25	(returns -1)
SCI11	MSTP\RC	24	(returns -1)
SCI12	MSTP\RB	4	k_sci_mstpb_sci12

Precondition

`k_sci_mstpb_sci0 == 31` for the descending formula to be correct

Postcondition

If return ≥ 0 , it is a valid MSTP\`rB bit index

Note

int8_t so -1 fits without consuming a valid bit position

Since

Version 1.0.0

Definition at line 688 of file [uart.c](#).

```
00689 {
00690     if (channel <= k_uart_max_mstpb_channel) {
00691         /* SCI0-SCI7: MSTPCRB bits 31-24, descending */
00692         return (int8_t)(k_sci_mstpb_sci0 - channel);
00693     }

8.139.3.7 internal`uart`enable`sci9`rx`isr()

```
void internal_uart_enable_sci9_rx_isr (
    volatile rx_sci_regs_t *const sci) [static]
```

Switch SCI9 to interrupt-driven RX mode.

Resets the ring-buffer head/tail, drains any pending RDR + clears boot-time error flags, programs the RXI9 vector priority/IER/IR, then sets SCR.RIE=1 so the RXI9 ISR begins firing on RDRF. HUM vector 102 = SCI9_RXI9, IER index 12 ((102>>3)=12), IER bit 6 ((102&7)=6). See comm_task RX overrun note at the top of this file.

Parameters

in	sci	SCI9 peripheral base (must be non-null)
----	-----	---

Precondition

Caller has set SCR=TX|RE before this call

Postcondition

SCR.RIE asserted, RXI9 vector enabled, ring drained

Since

Version 1.0.0

Definition at line 1109 of file [uart.c](#).

8.139.3.8 internal`uart`program`baud()

```
void internal_uart_program_baud (
    volatile rx_sci_regs_t *const sci,
    const uart_channel_t channel,
    const uint32_t baudrate) [static]
```

Program SMR/SEMR/BRR for the requested channel and baud.

Sets SMR=async-8N1, picks SEMR.ABCS=1 for SCI9 (lowers baud error from +1.72% to +0.16% at 115200 on PCLKA=120 MHz, see HUM 34.2.12), computes BRR via internal_calculate_brr, then waits k_uart_bit_time_ - delay_cycles for the new rate to settle. SEMR MUST be written before BRR because BRR is interpreted against whatever base clock SEMR selects.

Parameters

in	sci	SCI peripheral base (must be non-null)
in	channel	Validated SCI channel index
in	baudrate	Validated requested baud

Precondition

SCR=disabled before this call

Postcondition

SMR/SEMR/BRR programmed

Since

Version 1.0.0

Definition at line 1076 of file [uart.c](#).

```
01079 {

8.139.3.9 internal_uart_select_pclk()

```
uint32_t internal_uart_select_pclk (
    const uart\_channel\_t channel) [static]
```

Resolve the peripheral clock frequency for a given SCI channel.

SCIj (SCI0-SCI6) and SCIl (SCI12) are clocked by PCLKB. SCIn (SCI7-SCI11, extended region 0x000↵D0xxx) are clocked by PCLKA. Using the wrong clock produces a wrong BRR and a wrong baud rate.

Parameters

in	channel	Validated SCI channel index
----	---------	-----------------------------

Returns

uint32_t Peripheral clock in Hz

Precondition

channel < k_uart_max_channels

Since

Version 1.0.0

Definition at line 1047 of file [uart.c](#).

```
01048 {
01049     return (((uint8_t)channel >= k_uart_pclka_channel_min) &&
01050         ((uint8_t)channel <= k_uart_pclka_channel_max))
01051         ? k_pclka_hz
01052         : k_pclkb_hz;
01053 }
```

Here is the caller graph for this function:

8.139.3.10 internal_uart_validate_init()

```
rx_err_t internal_uart_validate_init (
    const uart_channel_config_t *const config,
    volatile rx_sci_regs_t **const sci_out) [static]
```

Initialize UART channel with specified configuration.

Configures and enables an SCI peripheral for asynchronous UART operation. Handles module clock enable, pin mux configuration, and SCI register setup.

Algorithm steps:

1. Validate configuration parameters (NULL check, channel range, baud rate)
2. Get SCI register base address for channel
3. Check if channel is already initialized (prevent double-init)
4. Enable SCI module clock (clear MSTPB bit)
5. Configure TX/RX pins via MPC and GPIO registers
6. Disable TX/RX during configuration ($S\backslash r = 0$)
7. Set serial mode: async, 8N1, PCLK/1 (SMR)
8. Calculate and set baud rate divisor (BRR)
9. Wait for 1 bit time (synchronization)
10. Enable TX and RX ($S\backslash r = 0x30$)
11. Mark channel as initialized

Precondition

config must point to valid [uart_channel_config_t](#) structure
config->channel must be in range [0, 12]
config->baudrate must be in valid range for PCLKB
Channel must not be already initialized

Postcondition

Channel configured for 8N1 async operation
TX and RX enabled and ready for use
s_channel_initialized[channel] set to true
TX/RX pins configured for peripheral function

Note

Not thread-safe - call once during initialization
Includes ~1ms delay for baud rate synchronization

Warning

Does not validate pin assignments against hardware

Thread Safety:

Not thread-safe. Call once per channel during system initialization.

Performance:

- Execution time: ~50 us (includes MPC and delay)
- Stack usage: 48 bytes

Example:

```
const uart_channel_config_t config = {
    .channel = k_uart_channel_9,
    .baudrate = 115200,
    .tx_gpio = k_rx_pb_7,
    .rx_gpio = k_rx_pb_6,
};

rx_err_t err = uart_init_channel(&config);
if (err != k_rx_ok) {
    // Handle error
}
```

See also

[uart_deinit_channel\(\)](#) Deinitialize channel
[uart_putc_channel\(\)](#) Transmit single character
[uart_channel_config_t](#) Configuration structure

Since

Version 1.0.0

Validate `uart_init_channel` arguments and resolve SCI base

Checks for null config, channel range, baud range, channel-already- initialized state. Resolves config->channel to its SCI peripheral base address.

Parameters

in	config	Caller's channel config (must be non-null)
out	sci_out	On success, set to the SCI peripheral base

Returns

`rx_err_t` Error code

Return values

<code>k_rx_ok</code>	All checks pass, *sci_out non-null
<code>k_rx_err_null_ptr</code>	config is nullptr
<code>k_rx_err_invalid_arg</code>	Bounds violation
<code>k_rx_err_invalid_state</code>	Channel already initialized

Precondition

sci_out non-null

Since

Version 1.0.0

Definition at line 1009 of file `uart.c`.

```

01011 {
01012     if (config == nullptr) {
01013         return k_rx_err_null_ptr;
01014     }
01015     if ((uint8_t)config->channel >= k_uart_max_channels) {

Here is the caller graph for this function:

8.139.3.11 uart_clear_rx_errors()

```
rx_err_t uart_clear_rx_errors (
    uart_channel_t channel) [nodiscard]
```

Clear sticky receive error flags (ORER/FER/PER) on a UART channel.

Reads SSR and writes back with the receive error bits masked to 0. Per HUM 34.2.7, those flags must be cleared before the receiver will latch further bytes. The RXI ISR clears them on every byte; this helper is the periodic-fallback path when an error latches without RDRF firing (e.g. line glitch on an idle bus).

Parameters

in	channel	SCI channel (0-12).
----	---------	---------------------

Returns

k_rx_ok on success, k_rx_err_invalid_arg if channel is invalid.

Definition at line 1834 of file [uart.c](#).

```

01835 {
01836     if ((uint8_t)channel >= k_uart_max_channels) {
01837         return k_rx_err_invalid_arg;
01838     }
01839     volatile rx_sci_regs_t* sci = sci_get_channel(channel);
01840     if (sci == nullptr) {
01841         return k_rx_err_invalid_arg;
01842     }
01843     const uint8_t ssr = sci->ssr;
01844     if ((ssr & k_sci_ssr_error_mask) != k_uart_flag_clear) {
01845         sci->ssr = (uint8_t)(ssr & ~k_sci_ssr_error_mask);
01846     }
01847     return k_rx_ok;
01848 }
```

References [k_sci_ssr_error_mask](#), [k_uart_flag_clear](#), [k_uart_max_channels](#), [sci_get_channel\(\)](#), and [rx_sci_regs_t::ssr](#).

Here is the call graph for this function:

8.139.3.12 `uart_debug_init()`

```
rx_err_t uart_debug_init (  
    void ) [nodiscard]
```

Initialize default debug UART channel (SCI9 at 115200 baud).

Initialize debug UART (SCI9, 115200 bps, 8N1).

Convenience function to initialize SCI9 with default debug settings:

- Channel: SCI9
- Baud rate: 115200 bps
- TX pin: PB7 (TXD9)
- RX pin: PB6 (RXD9)
- Format: 8N1 (8 data bits, no parity, 1 stop bit)

SCI9 is connected to the CY7C65213 USB-UART bridge on the STAR PCB, providing a virtual COM port when connected via USB.

Algorithm steps:

1. Create `uart_channel_config_t` with default values
2. Call `uart_init_channel()` with the configuration
3. Return result

Precondition

System clocks must be initialized (PCLKB = 60 MHz)

SCI9 must not be already initialized

Postcondition

SCI9 configured and ready for TX/RX at 115200 baud

`uart_debug_puts()`, `uart_debug_putc()` etc. are functional

Note

Call once during early system initialization

Call before any other debug output functions

Warning

Must be called before ThreadX starts if debug output is needed during init

Thread Safety:

Not thread-safe. Call once during startup before ThreadX.

Performance:

- Execution time: ~50 us
- Stack usage: 64 bytes

Example:

```
void system_init(void)
{
    // Initialize clocks first
    rx_clock_init();

    // Initialize debug UART for early output
    rx_err_t err = uart_debug_init();
    if (err != k_rx_ok) {
        // Cannot print error - no UART!
        // Could blink LED or set error flag
        return;
    }

    // Now we can print debug messages
    uart_debug_puts("[INFO] System starting...\n");
}
```

```
01978 {
01979     const uart_channel_config_t config = {
01980         .channel = (uart_channel_t)k_uart_debug_channel,
01981         .baudrate = k_uart_default_baudrate,
01982         .tx_gpio = (rx_port_pin_t)k_uart_debug_tx_gpio,
01983         .rx_gpio = (rx_port_pin_t)k_uart_debug_rx_gpio,
01984     };
01985     return uart_init_channel(&config);
01986 }
```

References [k_uart_debug_channel](#), [k_uart_debug_rx_gpio](#), [k_uart_debug_tx_gpio](#), [k_uart_default_baudrate](#), and [uart_init_channel\(\)](#).

Here is the call graph for this function:

```
void uart_debug_putc (
    const char data)
```

Transmit a single character on debug UART (SCI9).

Algorithm steps:

1. Call `uart_putc_channel(k_uart_debug_channel, data)`
2. Cast return value to `(void)` - errors discarded

uart_debug_init() must have been called successfully
SCI9 must be initialized and TX enabled

Postcondition

Character written to SCI9 TDR and transmission started
Any errors are silently discarded

Note

Error return from [uart_putc_channel\(\)](#) is intentionally discarded
For error-checked output use [uart_putc_channel\(\)](#) directly

Warning

Only available when RX_IS_SIMULATOR is 0 (hardware builds)

Thread Safety:

Not safe for concurrent access on SCI9 without external mutex.

Performance:

- Execution time: ~90 us @ 115200 baud
- Stack usage: 16 bytes

Example:

```
uart_debug_putc('A');    // Send 'A'  
uart_debug_putc('\r');  // Carriage return  
uart_debug_putc('\n');  // Line feed
```

Here is the call graph for this function:

Here is the caller graph for this function:

8.139.3.14 uart`debug`puthex()

```
void uart__debug__puthex (
    const uint32_t value,
    uint8_t digits)
```

Transmit 32-bit unsigned integer as hexadecimal string on debug UART.

Print a hexadecimal value on debug UART (SCI9).

Transmits "0x" prefix followed by the specified number of uppercase hex digits of value on SCI9. Digits are always printed most-significant first. The digits parameter is clamped to [k_uart_hex_min_digits, k_uart_hex_max_digits] (1-8) before use.

Algorithm steps:

1. Send "0x" prefix via `uart_debug_puts()`
2. Clamp digits to [1, 8]
3. Iterate nibbles from MSN to LSN (statically bounded by `k_uart_hex_max_digits`)
4. For each nibble index < digits, extract nibble and print uppercase hex char

Precondition

`uart_debug_init()` must have been called successfully
`uart_debug_puts()` and `uart_debug_putc()` must be functional

Postcondition

"0x" followed by digits uppercase hex characters transmitted on SCI9
digits clamped to [1, 8] if out of range

Note

Uses static lookup table `s_hex[]` for digit-to-character conversion
Always prefixes output with "0x"

Warning

Only available when `RX_IS_SIMULATOR` is 0 (hardware builds)

Thread Safety:

Not safe for concurrent access on SCI9 without external mutex.

Performance:

- Execution time: ~90 us per character @ 115200 baud
- Stack usage: 24 bytes

Example:

```
uart_debug_puts("Addr: ");  
uart_debug_puthex(0xDEADBEEF, 8); // Sends "0xDEADBEEF"  
uart_debug_puthex(0x42, 2);      // Sends "0x42"  
uart_debug_putc('\n');
```

Here is the call graph for this function:

8.139.3.15 uart'debug'putint()

```

void uart_debug_putint (
    const int32_t value)

```

Transmit signed 32-bit integer as decimal string on debug UART.

Print a signed integer on debug UART (SCI9).

Converts a signed 32-bit integer to a decimal ASCII string and transmits it on SCI9. Handles INT32_↔MIN correctly by using int64_t for the negation. Uses a fixed-size stack buffer (k_uart_int_buffer_size = 12) built in reverse then passed to `uart_debug_puts()`.

Algorithm steps:

1. Determine sign; compute abs_value as uint32_t
2. Null-terminate the buffer end
3. Build digits right-to-left (statically bounded by k_uart_int_buffer_size)
4. Prepend '-' if negative
5. Call `uart_debug_puts()` with the resulting substring pointer

Precondition

`uart_debug_init()` must have been called successfully
`uart_debug_puts()` must be functional

Postcondition

Decimal representation of value transmitted on SCI9
Leading zeros suppressed; negative values prefixed with '-'

Note

No return value - output errors are silently discarded
Buffer is stack-allocated; safe for re-entrant calls on different tasks

Warning

Only available when RX_IS_SIMULATOR is 0 (hardware builds)

Thread Safety:

Not safe for concurrent access on SCI9 without external mutex.

Performance:

- Execution time: ~90 us per digit @ 115200 baud + digit-loop overhead
- Stack usage: 32 bytes (buffer + locals)

Example:

```
uart_debug_puts("Value: ");  
uart_debug_putint(42); // Sends "42"  
uart_debug_putint(-2147483648); // Sends "-2147483648"  
uart_debug_putc('\n');
```

Here is the call graph for this function:

8.139.3.16 `uart_debug_puts()`

```
void uart_debug_puts (  
    const char * str)
```

Transmit null-terminated string on debug UART with newline conversion.

Transmit a null-terminated string on debug UART (SCI9).

Transmits a null-terminated string to SCI9 with automatic LF-to-`\r+LF` conversion for terminal compatibility. Enforces a maximum length of `k_uart_max_str_len` (256) characters per NASA Power of 10 Rule 2. Silently returns on NULL pointer to allow safe use in early init.

Algorithm steps:

1. Return immediately if `str` is `nullptr` (defensive, no error return)
2. For each character up to `k_uart_max_str_len`:
 - a. Stop at null terminator
 - b. If LF, send `\r` first
 - c. Send character via `uart_debug_putc()`

Precondition

`uart_debug_init()` must have been called successfully
`str` should point to a null-terminated string in valid memory

Postcondition

All characters up to null terminator transmitted to SCI9
Each LF replaced by `\r\n` in the transmitted output

Note

No return value - errors from `uart_debug_putc()` are silently discarded
String truncated at `k_uart_max_str_len` (256) characters

Warning

Only available when `RX_IS_SIMULATOR` is 0 (hardware builds)

Thread Safety:

Not safe for concurrent access on SCI9 without external mutex.

Performance:

- Execution time: ~90 us per character @ 115200 baud
- Stack usage: 24 bytes

Example:

```
uart_debug_puts("Hello, World!\n"); // Sends "Hello, World!\\r\\n"
uart_debug_puts("[INFO] Boot complete\n");
```

Here is the caller graph for this function:

8.139.3.17 `uart_deinit_channel()`

```
rx_err_t uart_deinit_channel (
    const uart\_channel\_t channel) [nodiscard]
```

Deinitialize UART channel and disable TX/RX.

Deinitialize SCI channel.

Disables transmit and receive on the specified SCI channel and marks it as uninitialized. The module clock is left running (safe to re-initialize without re-enabling). After this call the channel may be re-initialized with [uart_init_channel\(\)](#).

Algorithm steps:

1. Validate channel number (0-12)
2. Get SCI register base address
3. Write `S\r = 0` to disable TX and RX
4. Clear `s_channel_initialized[channel]`

Precondition

channel must be in range [0, 12]

Channel should be initialized before deinitializing (safe to call on uninit channel)

Postcondition

TX and RX disabled (`S\r = 0`)

`s_channel_initialized[channel]` set to false

Note

Not thread-safe - call during shutdown, not during normal operation

Module stop clock is NOT re-asserted (peripheral clock left enabled)

Thread Safety:

Not thread-safe. Do not call while another thread is using the channel.

Performance:

- Execution time: ~ 1 us
- Stack usage: 16 bytes

Example:

```
rx_err_t err = uart_deinit_channel(k_uart_channel_9);
if (err != k_rx_ok) {
    // Handle error (invalid channel)
}
// Channel is now disabled and can be re-initialized
```

Here is the call graph for this function:

8.139.3.18 `uart_getc_channel()`

```

rx_err_t uart_getc_channel (
    const uart\_channel\_t channel,
    char * data) [nodiscard]
  
```

Receive single character from UART channel (non-blocking).

Receive a single character from specified channel (non-blocking).

Attempts to read a single byte from the specified SCI channel's receive data register (RDR). This is a non-blocking operation - returns immediately with `k_rx_err_empty` if no data is available.

Algorithm steps:

1. Validate data pointer and channel number
2. Check channel initialization state
3. Get SCI register base address
4. Clear any error flags (ORER, FER, PER)
5. Check RDRF flag (Receive Data Register Full)
 - If not set, return k_rx_err_empty immediately
6. Read data byte from RDR register
7. Clear RDRF flag (read SSR, write back with RDRF=0)

Error flag handling:

- ORER (Overrun Error): Previous data overwritten before read
- FER (Framing Error): Stop bit not detected
- PER (Parity Error): Parity mismatch (not used in 8N1 mode)

Precondition

Channel must be initialized via [uart_init_channel\(\)](#)
data must point to valid memory for single char

Postcondition

On success, *data contains received byte
RDRF flag cleared (ready for next byte)
Error flags cleared if any were set

Note

Non-blocking - returns immediately if no data
Clears error flags automatically before read
Single byte buffer - call frequently to avoid overrun

Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

Performance:

- Execution time: ~5 us (no wait)
- Stack usage: 16 bytes

Example (Polling Loop):

```
char c;
rx_err_t err;

// Poll for incoming data
do {
    err = uart_getc_channel(k_uart_channel_9, &c);
    if (err == k_rx_ok) {
        process_character(c);
    }
} while (err == k_rx_ok); // Continue while data available
```

Example (Timeout Loop):

```
char c;
uint32_t timeout = 100000;

while (timeout > 0) {
    rx_err_t err = uart_getc_channel(k_uart_channel_9, &c);
    if (err == k_rx_ok) {
        // Got data
        break;
    }
    timeout--;
}

if (timeout == 0) {
    // No data received within timeout
}
```

8.139.3.20 uart_putc_channel()

```

rx_err_t uart_putc_channel (
    const uart_channel_t channel,
    const char data) [nodiscard]

```

Transmit single character on UART channel.

Transmit a single character on specified channel.

Transmits a single byte on the specified SCI channel. Waits for the transmit data register to become empty (TDRE flag) with timeout protection, then writes the data to TDR. Uses polling mode (no interrupts).

Algorithm steps:

1. Validate channel number (0-12)
2. Check channel is initialized
3. Get SCI register base address
4. Wait for TDRE flag with timeout (`k_uart_tx_timeout` iterations)
5. Write data byte to TDR register
6. Clear TDRE flag (read SSR, write back with TDRE=0)

Character transmission timing at 115200 baud:

- Start bit: 8.68 us
- 8 data bits: 69.44 us
- Stop bit: 8.68 us
- Total: ~86.8 us per character

Precondition

Channel must be initialized via [uart_init_channel\(\)](#)
UART TX must be enabled (happens during init)

Postcondition

Character written to TDR and transmission started
TDRE flag cleared (TDR occupied)

Note

Blocking call - waits for TDRE flag
Timeout prevents infinite wait if hardware fails

Warning

May block for up to ~100ms if TX line is held low

Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

Performance:

- Execution time: ~90 us @ 115200 baud (one character time)
- Stack usage: 16 bytes

Example:

```
// Send single character
rx_err_t err = uart_putc_channel(k_uart_channel_9, 'A');
if (err != k_rx_ok) {
    // Handle error
}

// Send carriage return + line feed
uart_putc_channel(k_uart_channel_9, '\\r');
uart_putc_channel(k_uart_channel_9, '\\n');
```

Here is the call graph for this function:

Here is the caller graph for this function:

8.139.3.21 `uart_puts_channel()`

```
rx_err_t uart_puts_channel (
    const uart\_channel\_t channel,
    const char * str)  [nodiscard]
```

Transmit null-terminated string on UART channel with newline conversion.

Transmit a null-terminated string on specified channel.

Transmits a null-terminated string with automatic LF to \r+LF conversion for terminal compatibility. Enforces maximum string length (`k_uart_max_str_len = 256`) to comply with NASA Power of 10 Rule 2 (bounded loops).

Algorithm steps:

1. Validate string pointer (NULL check)
2. Validate channel number and initialization state
3. For each character up to `k_uart_max_str_len`: a. Check for null terminator (success exit) b. If ' ', send '\r' first (\r+LF conversion) c. Transmit character via [uart_putc_channel\(\)](#) d. Propagate any errors immediately
4. If limit reached without terminator, return `k_rx_err_invalid_size`

Newline conversion:

- Input ' ' (LF) -> Output '\r\n' (\r+LF)
- Required for Windows terminals (e.g., PuTTY, TeraTerm)
- Ensures cursor returns to column 0 before line feed

Precondition

Channel must be initialized via [uart_init_channel\(\)](#)
 str must point to null-terminated string in valid memory

Postcondition

All characters transmitted including converted newlines
 On error, partial string may have been transmitted

Note

Blocking call - waits for each character to transmit
 String length limited to 256 characters for safety

Warning

Long strings may take significant time (256 chars ~ 22ms @ 115200)

Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

Performance:

- Execution time: ~90 us per character @ 115200 baud
- Stack usage: 24 bytes
- Example: 100-char string ~ 9 ms

Example:

```
// Simple string
uart_puts_channel(k_uart_channel_9, "Hello, World!\n");
// Output: "Hello, World!\r\n"

// Multiple lines
uart_puts_channel(k_uart_channel_9, "Line 1\nLine 2\nLine 3\n");
// Output: "Line 1\r\nLine 2\r\nLine 3\r\n"

// Error handling
rx_err_t err = uart_puts_channel(k_uart_channel_9, msg);
if (err != k_rx_ok) {
    // Partial transmission may have occurred
}
```

References [k_uart_max_channels](#), [k_uart_max_str_len](#), [s_channel_initialized](#), and [uart_putc_channel\(\)](#).

Referenced by [uart_debug_puts\(\)](#).

Here is the call graph for this function:

Here is the caller graph for this function:

8.139.3.22 `uart_read_channel()`

```
rx_err_t uart_read_channel (  
    const uart\_channel\_t channel,  
    uint8_t * data,  
    uint16_t length,  
    uint16_t * bytes_read) [nodiscard]
```

Read available bytes from UART channel (non-blocking).

Read available data from specified channel (non-blocking).

Reads up to length bytes from the specified SCI channel using [uart_getc_channel\(\)](#). Stops immediately when no more data is available (RDRE flag not set) rather than waiting. Actual bytes received is reported via bytes_read.

Algorithm steps:

1. Validate data and bytes_read pointers (NULL check)
2. Validate channel number and initialization state
3. Set *bytes_read = 0
4. For each slot in [0, length): a. Call [uart_getc_channel\(\)](#); if k_rx_err_empty, break (done) b. On other error, propagate immediately c. Store byte and increment *bytes_read
5. Return k_rx_ok (even if zero bytes were read)

Precondition

Channel must be initialized via [uart_init_channel\(\)](#)
data must point to at least length bytes of writable memory

Postcondition

*bytes_read set to actual number of bytes received
data[0..*bytes_read-1] contain the received bytes

Note

Non-blocking - returns immediately with whatever data is available
k_rx_ok with *bytes_read == 0 means no data was available

Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

Performance:

- Execution time: ~5 us per byte received + ~5 us when no data
- Stack usage: 24 bytes

Example:

```
uint8_t  buf[64];
uint16_t count = 0;
rx_err_t err  = uart_read_channel(k_uart_channel_9, buf, sizeof(buf), &count);
if (err == k_rx_ok && count > 0) {
    process_bytes(buf, count);
}
```

Here is the call graph for this function:

8.139.3.23 uart'rx'available()

```

rx_err_t uart_rx_available (
    const uart\_channel\_t channel,
    bool * available) [nodiscard]

```

Check if receive data is available on UART channel.

Check if receive data is available on channel.

Checks the RDRF (Receive Data Register Full) flag in the SSR register of the specified SCI channel. Provides a non-destructive peek at receive availability without consuming any data from the buffer.

Algorithm steps:

1. Validate available pointer (NULL check)
2. Validate channel number and initialization state
3. Get SCI register base address
4. Read SSR and test RDRF bit; store boolean result in *available

Precondition

Channel must be initialized via [uart_init_channel\(\)](#)
available must point to valid bool storage

Postcondition

*available reflects current RDRF state
No data is consumed from the receive buffer

Note

Non-destructive - does not read RDR or clear any flags
RDRF can be set again immediately after reading if UART is receiving

Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

Performance:

- Execution time: ~2 us
- Stack usage: 16 bytes

Example:

```
bool ready = false;
if (uart_rx_available(k_uart_channel_9, &ready) == k_rx_ok && ready) {
    char c;
    uart_getc_channel(k_uart_channel_9, &c);
}
```

Here is the call graph for this function:

8.139.3.24 `uart_write_channel()`

```
rx_err_t uart_write_channel (  
    const uart\_channel\_t channel,  
    const uint8_t * data,  
    uint16_t length) [nodiscard]
```

Write binary data to UART channel without newline conversion.

Write buffer to specified channel.

Transmits a block of raw bytes on the specified SCI channel using [uart_putc_channel\(\)](#) for each byte. No LF-to-`\r`+LF conversion is performed, making this function suitable for binary protocol data.

Algorithm steps:

1. Validate data pointer (NULL check)
2. Validate channel number and initialization state
3. For each byte in `[0, length)`: call [uart_putc_channel\(\)](#) and propagate errors

Precondition

Channel must be initialized via [uart_init_channel\(\)](#)
data must point to at least length bytes of valid memory

Postcondition

All length bytes transmitted in order
On error, partial data may have been transmitted

Note

Blocking call - waits for each byte to be accepted by TDR
No newline conversion - use [uart_puts_channel\(\)](#) for text output

Thread Safety:

Thread-safe for different channels. Not safe for same channel without mutex.

Performance:

- Execution time: ~90 us per byte @ 115200 baud
- Stack usage: 24 bytes

Example:

```
const uint8_t frame[] = {0xAA, 0x55, 0x01, 0x02, 0x03};
rx_err_t err = uart_write_channel(k_uart_channel_9, frame, sizeof(frame));
if (err != k_rx_ok) {
    // Handle partial write
}
```

00060  * | MCU | Renesas RX72N | SCI peripheral required |
00061  * | Channels | SCI0-SCI12 | 13 channels total |
00062  * | Clock | PCLKB (SCI0-6,12) / PCLKA (SCI7-11) | Per-channel BRR clock |
00063  * | TX Pin | Port pin configured as output | Requires MPC configuration |
00064  * | RX Pin | Port pin configured as input | Requires MPC configuration |
00065  * | USB Bridge | CY7C65213 (default) | For SCI9 debug channel |
00066  *
00067  * @par Default Debug Configuration (SCI9):
00068  *
00069  * | Parameter | Value | Notes |
00070  * |-----|-----|-----|
00071  * | Channel | SCI9 | Connected to USB-UART bridge |
00072  * | TX Pin | PB7 (TXD9) | Output, peripheral mode |
00073  * | RX Pin | PB6 (RXD9) | Input, peripheral mode |
00074  * | Baud Rate | 115200 bps | Standard debug speed |
00075  * | Data Bits | 8 | Fixed |
00076  * | Parity | None | Fixed |
00077  * | Stop Bits | 1 | Fixed |
00078  *
00079  * ### Baud Rate Calculation
00080  *
00081  * The SCI baud rate formula for n=0 (CKS=00, PCLK/1):

```

```

00082 *
00083 * @f
00084 * \text{BRR} = \frac{\text{PCLK}}{32 \times B} - 1
00085 * @f
00086 *
00087 * f_PCLK depends on the channel group (manual section 5 I/O register table):
00088 * - SCI0-SCI6, SCI12 (SCIj/SCIh): PCLKB (k_pclkb_hz, 60 MHz)
00089 * - SCI7-SCI11 (SCIi, extended 0x00D0xxx): PCLKA (k_pclka_hz, 120 MHz)
00090 *
00091 * Note: rx72n_clock.h is authoritative for PCLK frequencies; trust the header
00092 * over any older bench note. PCLKB = 60 MHz on this platform.
00093 *
00094 * @par Supported Baud Rates (at PCLKB = 60 MHz, for SCI0-SCI6/SCI12):
00095 *
00096 * | Baud Rate | BRR | Actual Rate | Error |
00097 * |-----|-----|-----|-----|
00098 * | 9600 | 194 | 9615 | +0.16% |
00099 * | 19200 | 96 | 19231 | +0.16% |
00100 * | 38400 | 47 | 38462 | +0.16% |
00101 * | 57600 | 31 | 58594 | +1.73% |
00102 * | 115200 | 15 | 117188 | +1.73% |
00103 * | 230400 | 7 | 234375 | +1.73% |
00104 * | 460800 | 3 | 468750 | +1.73% |
00105 * | 921600 | 1 | 937500 | +1.73% |
00106 *
00107 * ## Performance Characteristics
00108 *
00109 * | Operation | Execution Time | Stack Usage | Notes |
00110 * |-----|-----|-----|-----|
00111 * | uart_init_channel | ~50 us | 48 bytes | Includes MPC configuration |
00112 * | uart_putc_channel | ~90 us @ 115200 | 16 bytes | Includes wait for TDRE |
00113 * | uart_puts_channel | ~90 us/char | 24 bytes | With LF->\r\n conversion |
00114 * | uart_getc_channel | ~5 us | 16 bytes | Non-blocking if no data |
00115 * | uart_debug_init | ~50 us | 64 bytes | Wrapper for SCI9 |
00116 *
00117 * @par Memory Footprint:
00118 * - Code size: ~2 KB (all functions)
00119 * - Static data: 13 bytes (s_channel_initialized array)
00120 * - Stack usage: < 64 bytes (deepest call)
00121 * - Heap usage: 0 bytes (zero dynamic allocation)
00122 *
00123 * ## Thread Safety
00124 *
00125 * | Function | Thread Safe? | Notes |
00126 * |-----|-----|-----|
00127 * | uart_init_channel | [FAIL] No | Call once per channel during init |
00128 * | uart_deinit_channel | [FAIL] No | Call once during shutdown |
00129 * | uart_putc_channel | [WARN] Partial | Safe if different channels |
00130 * | uart_puts_channel | [WARN] Partial | Safe if different channels |
00131 * | uart_getc_channel | [WARN] Partial | Safe if different channels |
00132 * | uart_debug_* | [WARN] Partial | All use same channel (SCI9) |
00133 *
00134 * **Note:** Multiple threads can safely use different UART channels simultaneously.
00135 * For shared channel access, use external mutex protection.
00136 *
00137 * @par Module Dependencies:
00138 *
00139 * **This module depends on:**
00140 * - `hardware.h` - Hardware configuration and channel constants
00141 * - `rx72n_clock.h` - PCLKB frequency definition
00142 * - `rx72n_regs.h` - SCI register definitions
00143 * - `rx_mpc.h` - Pin mux configuration
00144 * - `rx_port_utils.h` - GPIO port utilities
00145 * - `rx_register_protection.h` - PR register protection
00146 *
00147 * **This module is used by:**
00148 * - `rx_log.c` - Logging subsystem output
00149 * - `main.c` - Debug output during initialization
00150 * - `comm_task.c` - Communication task debug messages
00151 *
00152 * @par NASA Power of 10 Compliance:
00153 *
00154 * | Rule | Status | Implementation |
00155 * |-----|-----|-----|
00156 * | 1. Simple control flow | [OK] | No goto/setjmp/recursion |
00157 * | 2. Fixed loop bounds | [OK] | All loops use k_uart_max_str_len limit |
00158 * | 3. No dynamic allocation | [OK] | Zero malloc/free, static buffers only |
00159 * | 4. Small functions | [OK] | All functions < 60 lines |
00160 * | 5. Assertions (>=2/func) | [OK] | Parameter validation + state checks |
00161 * | 6. Narrow scope | [OK] | Static file-scope state, local variables |
00162 * | 7. Check return values | [OK] | All rx_err_t returns propagated |
00163 * | 8. Limited preprocessor | [OK] | C23 typed enums only |
00164 * | 9. Pointer restrictions | [OK] | Single-level pointers, no arithmetic |
00165 * | 10. Compiler warnings | [OK] | -Wall -Wextra -Werror clean |
00166 *
00167 * @par SOLID Principles:
00168 *

```

```

00169 **Single Responsibility (S):**
00170 * - This module handles ONLY UART communication
00171 * - Separate from higher-level logging (rx_log.c)
00172 * - Separate from protocol parsing (rx_frame.c)
00173 *
00174 **Open/Closed (O):**
00175 * - New baud rates supported without code changes
00176 * - New channels added via configuration structure
00177 * - Pin assignments configurable per-channel
00178 *
00179 **Liskov Substitution (L):**
00180 * - All channel functions accept any valid channel
00181 * - Consistent rx_err_t return semantics
00182 * - Debug functions are simple wrappers
00183 *
00184 **Interface Segregation (I):**
00185 * - Separate init/deinit from TX/RX operations
00186 * - Debug functions provide simplified interface
00187 * - Channel functions provide full control
00188 *
00189 **Dependency Inversion (D):**
00190 * - Uses abstract rx_port_pin_t for pin specification
00191 * - Uses rx_mpc module for pin configuration
00192 * - Uses rx_err_t for standardized error handling
00193 *
00194 * @see hardware.h Hardware configuration and constants
00195 * @see rx72n_sci_regs.h SCI register definitions
00196 * @see rx_mpc.h Pin mux configuration API
00197 * @see rx_log.h Higher-level logging that uses this driver
00198 *

00297
00298 /**
00299  * @enum uart_validation_limits_t
00300  * @brief Baud rate validation bounds for uart_init_channel() parameter checking
00301  *
00302  * @details
00303  * Defines the closed interval [k_uart_baudrate_min, k_uart_baudrate_max] that
00304  * every requested baud rate must satisfy before the driver attempts to program
00305  * the BRR register.
00306  *
00307  * The maximum is derived directly from the BRR formula for n=0 (CKS=00):
00308  * @f
00309  * \text{BRR} = \frac{\text{PCLKB}}{32 \times B} - 1 \geq 0
00310  * \implies B \leq \frac{\text{PCLKB}}{32}
00311  * @f
00312  * A BRR of 0 corresponds to the fastest achievable baud rate at the current
00313  * PCLKB frequency, so requesting anything higher would underflow the register.
00314  *
00315  * The minimum is 1 bps, which prevents a divide-by-zero in the BRR formula.
00316  * In practice, any baud rate below ~9600 is impractical on a 60 MHz PCLKB, but
00317  * the lower bound is kept permissive to avoid false negatives during testing.
00318  *
00319  * @invariant k_uart_baudrate_min must be > 0 to prevent division by zero in
00320  * internal_calculate_brr().
00321  * @invariant k_uart_baudrate_max must equal k_pclkb_hz / k_brr_divisor_n0 so
00322  * that the computed BRR is always >= 0 (i.e., no register underflow).
00323  *
00324  * @par Example:
00325  * @code{.c}
00326  * // Validation performed inside uart_init_channel()
00327  * if ((config->baudrate < k_uart_baudrate_min) ||
00328      (config->baudrate > k_uart_baudrate_max)) {
00329     return k_rx_err_invalid_arg;
00330 }
00331 * @endcode
00332 *
00333 * @see uart_init_channel() Uses these bounds to validate the baudrate field
00334 * @see internal_calculate_brr() Computes the actual BRR register value
00335 * @see brr_constants_t BRR formula divisor constants
00336 *
00337 * @since Version 1.0.0

00414  * UART TX/RX pin setup. A bit mask for a specific pin is formed by shifting
00415  * this value left by the pin index obtained from rx_pin_from_pin().
00416  *
00417  * @invariant k_uart_gpio_bit_set must equal 1 so that left-shifting by a pin
00418  * index produces an isolated single-bit mask.
00419  *
00420  * @par Example:
00421  * @code{.c}
00422  * // Build the TX pin mask and set the direction bit
00423  * const uint8_t tx_pin = rx_pin_from_pin(tx_gpio);
00424  * const uint8_t tx_pin_mask = (uint8_t)(k_uart_gpio_bit_set « tx_pin);
00425  * tx_port_base->pdr |= tx_pin_mask; // Set output direction
00426  * tx_port_base->pmr |= tx_pin_mask; // Switch to peripheral mode
00427  * @endcode

```

```

=====
00447 * Interrupt-driven RX ring buffer for SCI9
00448 *
=====
00449 *
00450 * SCI9 on the RX72N has no hardware RX FIFO. Polling RDRF in a 10 ms task
00451 * loop (rx_comm_manager's 100 Hz cadence) catches roughly 1 byte per poll
00452 * while the gateway can send ~115 bytes / 10 ms at 115200 baud. Any byte
00453 * arriving while RDRF is still set from the previous byte triggers an
00454 * overrun (SSR.ORER) and is lost.
00455 *
00456 * Fix: enable the SCI9_RXI9 interrupt (vector 102) and copy every byte
00457 * into a lock-free single-producer / single-consumer ring buffer as it
00458 * arrives. uart_getc_channel (and uart_rx_available) for SCI9 then reads
00459 * from the ring instead of polling RDR directly. HUM section 34.2.8
00460 * describes the RXI request behavior.

00478 /**
00479 * @brief Calculate the 8-bit BRR register value for a target baud rate
00480 *
00481 * @details
00482 * Computes the value to be written to the SCI Bit Rate Register (BRR) so that
00483 * the SCI peripheral generates the requested baud rate from PCLKB. The
00484 * general RX72N SCI baud rate formula for asynchronous mode is:
00485 *
00486 * @f[
00487 * \text{BRR} = \frac{\text{PCLKB}}{64 \times 2^{2n-1} \times B} - 1
00488 * @f]
00489 *
00490 * This driver always uses n=0 (CKS bits = 0b00, clock source = PCLK/1), which
00491 * simplifies to:
00492 *
00493 * @f[
00494 * \text{BRR} = \frac{\text{PCLK}}{32 \times B} - 1
00495 * @f]
00496 *
00497 * The caller supplies the correct PCLK frequency for the target channel:
00498 * - SCI0-SCI6, SCI12 (SCIj/SCIh, standard region): use k_pclkb_hz
00499 * - SCI7-SCI11 (SCIi, extended region 0x000D0xxx): use k_pclka_hz
00500 *
00501 * This distinction matters when PCLKA != PCLKB. rx72n_clock.h is the
00502 * authoritative source for PCLK frequencies (k_pclka_hz, k_pclkb_hz, etc.);
00503 * trust the header over any older bench note.
00504 *
00505 * **Algorithm steps:**
00506 * 1. Guard against baudrate == 0 (return k_brr_max_value as a safe sentinel).
00507 * 2. Guard against baudrate > pclk_hz/32 (return k_brr_min_value).
00508 * 3. Compute divisor_result = pclk_hz / (32 * B) using integer arithmetic.

```

```

00509 * 4. Guard against divisor_result <= 1 to prevent underflow from the -1 offset.
00510 * 5. Compute BRR = divisor_result - 1.
00511 * 6. Clamp the result to k_brr_max_value (255) if the integer exceeds the
00512 * 8-bit range (indicates a baud rate too slow for this clock).
00513 * 7. Return the clamped 8-bit result.
00514 *
00515 *
00516 *
00517 * @pre baudrate validated by caller; pclk_hz must be non-zero
00518 * @pre k_brr_divisor_n0 must be non-zero compile-time constant
00519 *
00520 * @post Return value is always in [0, 255]
00521 * @post Caller must write the returned value to sci->brr before enabling TX/RX
00522 *
00523 * @note Stateless pure function; safe to call from any context including ISR
00524 * @note Always uses n=0 (CKS=00); support for n=1..3 is not implemented
00525 *
00526 * @par Example:
00527 * @code{.c}
00528 * // SCI9 uses PCLKA (SCIi extended region), ABCS=1 for baud accuracy
00529 * sci->brr = internal_calculate_brr(115200U, k_pclka_hz, true);
00530 * @endcode
00531 *
00532 * @see uart_init_channel() Caller that selects pclk_hz and writes sci->brr
00533 * @see brr_constants_t Constants used in the BRR formula
00534 *
00535 * @since Version 1.0.0
00536 */

00569     }
00570
00571     const uint8_t result = (uint8_t)brr_value;
00572
00573     return result;
00574 }
00575
00576 /**
00577 * @brief Clear receive error flags in the SCI Serial Status Register (SSR)
00578 *
00579 * @details
00580 * Reads the SSR register and writes it back with the three receive error flag
00581 * bits masked out, which clears any pending ORER (Overrun Error), FER
00582 * (Framing Error), and PER (Parity Error) conditions on the SCI channel.
00583 *
00584 * The RX72N SCI peripheral requires a read-modify-write sequence to clear
00585 * error flags: the hardware only allows clearing a flag by writing 0 to it
00586 * while keeping the rest of the register unchanged. Writing 1 to an already-
00587 * set flag has no effect (the write is ignored).
00588 *
00589 * **Algorithm steps:**
00590 * 1. Guard: return immediately if sci is nullptr (NASA Power of 10 Rule 5).
00591 * 2. Read the current value of sci->ssr into a local volatile variable.
00592 * 3. Cast-to-void the read result to suppress the unused-variable warning while
00593 *    still ensuring the volatile read is not optimised away.
00594 * 4. Write sci->ssr = (ssr & ~k_sci_ssr_error_mask) to clear bits [5:3]
00595 *    (ORER, FER, PER) while preserving all other SSR bits.

```

```

00596 *
00597 * **Error flag bit positions in SSR:**
00598 * | Bit | Flag | Description |
00599 * |-----|-----|
00600 * | 5 | ORER | Overrun Error - new data arrived before previous data was read |
00601 * | 4 | FER | Framing Error - no valid stop bit detected |
00602 * | 3 | PER | Parity Error - parity mismatch (unused in 8N1 mode) |
00603 *
00604 *
00605 * @pre sci must point to a valid, hardware-mapped rx_sci_regs_t register block
00606 * @pre The SCI module clock must be enabled (MSTP\|rB bit cleared) before
00607 * any SSR access; undefined behaviour otherwise
00608 *
00609 * @post ORER, FER, and PER bits in sci->ssr are cleared (written to 0)
00610 * @post All other SSR bits (TDRE, RDRF, TEND, MPB, MPBT) are preserved
00611 *
00612 * @note This function is intentionally void-returning; the caller (uart_getc_channel)
00613 * checks for errors before calling and does not need a return code
00614 * @note The intermediate volatile read prevents the compiler from merging the
00615 * read and write into a single store, which would miss the read requirement
00616 *
00617 * @par Thread Safety:
00618 * Not thread-safe. SSR is a read-modify-write target; concurrent access from
00619 * two threads on the same channel can corrupt flag state. External mutex
00620 * protection is required if multiple threads share a channel.
00621 *
00622 * @par Performance:
00623 * - Execution time: ~3 cycles (volatile read + mask + volatile write)
00624 * - Stack usage: 4 bytes (one volatile uint8_t local)
00625 *
00626 * @par Example:
00627 * @code{.c}
00628 * volatile rx_sci_regs_t* sci = sci_get_channel(k_uart_channel_9);
00629 * if (sci != nullptr) {
00630 * // Clear any stale error flags before reading receive data
00631 * internal_clear_errors(sci);
00632 * const char data = (char)sci->rdr;
00633 * }
00634 * @endcode
00635 *
00636 * @see uart_getc_channel() Caller that invokes this before reading RDR
00637 * @see sci_register_values_t k_sci_ssr_error_mask bitmask definition
00638 * @see uart_rx_available() Non-destructive receive availability check

00753 * @brief Configure the GPIO and MPC pin-mux settings for a UART TX/RX pin pair
00754 *
00755 * @details
00756 * Prepares the two GPIO pins required for SCI UART operation by programming
00757 * the Multi-Function Pin Controller (MPC) and the Port Direction/Mode registers
00758 * in the correct order. The RX72N hardware requires that:
00759 * - MPC is configured before switching a pin to peripheral mode (PMR)
00760 * - TX pin is driven as an output; RX pin is configured as an input
00761 * - Both pins are switched to peripheral mode (PMR bit = 1) last
00762 *
00763 * **Algorithm steps:**
00764 * 1. Extract the port number and pin number from each rx_port_pin_t using
00765 *    rx_port_from_pin() and rx_pin_from_pin().
00766 * 2. Validate that both pin numbers are <= k_rx_pin_max (7); return
00767 *    k_rx_err_invalid_arg if out of range. (Lower-bound check is omitted
00768 *    because pin numbers are uint8_t and k_rx_pin_min == 0, which would
00769 *    trigger -Wtype-limits.)

```

```

00770 * 3. Obtain volatile port register base pointers via rx_port_get_base(); return
00771 * k_rx_err_invalid_arg if either is nullptr (invalid port number).
00772 * 4. Call rx_mpc_set_sci(tx_gpio) to set the TX pin's PFS register to the SCI
00773 * TXD function; propagate any error immediately.
00774 * 5. Call rx_mpc_set_sci(rx_gpio) to set the RX pin's PFS register to the SCI
00775 * RXD function; propagate any error immediately.
00776 * 6. Build per-pin bitmasks (k_uart_gpio_bit_set « pin_number).
00777 * 7. Set PDR bit for TX pin (output direction) and PMR bit for TX pin
00778 * (peripheral mode).
00779 * 8. Clear PDR bit for RX pin (input direction) and set PMR bit for RX pin
00780 * (peripheral mode).
00781 * 9. Return k_rx_ok.
00782 *
00783 * **MPC write protection:**
00784 * rx_mpc_set_sci() internally handles the PFSWE unlock/lock sequence, so this
00785 * function does not need to touch the PFSWE bit directly.
00786 *
00787 * **Pin direction and mode summary:**
00788 * | Pin | PDR (direction) | PMR (mode) |
00789 * |-----|-----|
00790 * | TX | 1 (output) | 1 (peripheral) |
00791 * | RX | 0 (input) | 1 (peripheral) |
00792 *
00793 *
00794 *
00795 *
00796 * @pre tx_gpio and rx_gpio must correspond to physically valid RX72N port pins
00797 * @pre The SCI module clock must already be enabled (MSTP\\rB bit cleared) so
00798 * that the SCI TXD/RXD MPC function codes are accepted
00799 *
00800 * @post TX pin: PDR bit set (output), PMR bit set (peripheral function)
00801 * @post RX pin: PDR bit cleared (input), PMR bit set (peripheral function)
00802 * @post Both pins' PFS registers configured for SCI TX/RX function via MPC
00803 *
00804 * @note Pin validation only checks upper bound (>k_rx_pin_max); lower bound
00805 * (0) is omitted to avoid the -Wtype-limits compiler warning triggered by
00806 * comparing an unsigned type to 0
00807 * @warning Passing the same pin for both TX and RX produces undefined hardware
00808 * behaviour; no duplicate-pin check is performed
00809 *
00810 * @par Thread Safety:
00811 * Not thread-safe. PDR/PMR are read-modify-write targets shared with all GPIO
00812 * operations on the same port. Call only during single-threaded initialization.
00813 *
00814 * @par Performance:
00815 * - Execution time: ~10 us (dominated by two rx_mpc_set_sci() calls)
00816 * - Stack usage: 32 bytes (four uint8_t locals + two pointer locals)

01249 * @brief Transmit single character on UART channel
01250 *
01251 * @details
01252 * Transmits a single byte on the specified SCI channel. Waits for the transmit
01253 * data register to become empty (TDRE flag) with timeout protection, then writes
01254 * the data to TDR. Uses polling mode (no interrupts).
01255 *
01256 * **Algorithm steps:**
01257 * 1. Validate channel number (0-12)
01258 * 2. Check channel is initialized
01259 * 3. Get SCI register base address
01260 * 4. Wait for TDRE flag with timeout (k_uart_tx_timeout iterations)
01261 * 5. Write data byte to TDR register
01262 * 6. Clear TDRE flag (read SSR, write back with TDRE=0)
01263 *
01264 * **Character transmission timing at 115200 baud:**
01265 * - Start bit: 8.68 us
01266 * - 8 data bits: 69.44 us
01267 * - Stop bit: 8.68 us
01268 * - **Total**: ~86.8 us per character
01269 *
01270 *
01271 *
01272 *
01273 * @pre Channel must be initialized via uart_init_channel()
01274 * @pre UART TX must be enabled (happens during init)
01275 *
01276 * @post Character written to TDR and transmission started
01277 * @post TDRE flag cleared (TDR occupied)
01278 *
01279 * @note Blocking call - waits for TDRE flag
01280 * @note Timeout prevents infinite wait if hardware fails
01281 * @warning May block for up to ~100ms if TX line is held low
01282 *
01283 * @par Thread Safety:
01284 * Thread-safe for different channels. Not safe for same channel without mutex.
01285 *
01286 * @par Performance:
01287 * - Execution time: ~90 us @ 115200 baud (one character time)
01288 * - Stack usage: 16 bytes
01289 *

```

```

01662  * @brief Read available bytes from UART channel (non-blocking)
01663  *
01664  * @details
01665  * Reads up to 'length' bytes from the specified SCI channel using
01666  * uart_getc_channel(). Stops immediately when no more data is available
01667  * (RDRF flag not set) rather than waiting. Actual bytes received is
01668  * reported via 'bytes_read'.
01669  *
01670  * **Algorithm steps:**
01671  * 1. Validate data and bytes_read pointers (NULL check)
01672  * 2. Validate channel number and initialization state
01673  * 3. Set *bytes_read = 0
01674  * 4. For each slot in [0, length):
01675  *     a. Call uart_getc_channel(); if k_rx_err_empty, break (done)
01676  *     b. On other error, propagate immediately
01677  *     c. Store byte and increment *bytes_read
01678  * 5. Return k_rx_ok (even if zero bytes were read)
01679  *
01680  *
01681  *
01682  *
01683  *
01684  *
01685  * @pre Channel must be initialized via uart_init_channel()
01686  * @pre data must point to at least 'length' bytes of writable memory
01687  *
01688  * @post *bytes_read set to actual number of bytes received
01689  * @post data[0..*bytes_read-1] contain the received bytes
01690  *
01691  * @note Non-blocking - returns immediately with whatever data is available
01692  * @note k_rx_ok with *bytes_read == 0 means no data was available
01693  *
01694  * @par Thread Safety:
01695  * Thread-safe for different channels. Not safe for same channel without mutex.
01696  *
01697  * @par Performance:
01698  * - Execution time: ~5 us per byte received + ~5 us when no data
01699  * - Stack usage: 24 bytes
01700  *

02103 /**
02104 * @brief Transmit signed 32-bit integer as decimal string on debug UART
02105 *
02106 * @details
02107 * Converts a signed 32-bit integer to a decimal ASCII string and transmits
02108 * it on SCI9. Handles INT32_MIN correctly by using int64_t for the negation.
02109 * Uses a fixed-size stack buffer (k_uart_int_buffer_size = 12) built in
02110 * reverse then passed to uart_debug_puts().
02111 *
02112 * **Algorithm steps:**
02113 * 1. Determine sign; compute abs_value as uint32_t
02114 * 2. Null-terminate the buffer end
02115 * 3. Build digits right-to-left (statically bounded by k_uart_int_buffer_size)
02116 * 4. Prepend '-' if negative
02117 * 5. Call uart_debug_puts() with the resulting substring pointer
02118 *
02119 *
02120 * @pre uart_debug_init() must have been called successfully
02121 * @pre uart_debug_puts() must be functional
02122 *
02123 * @post Decimal representation of value transmitted on SCI9
02124 * @post Leading zeros suppressed; negative values prefixed with '-'
02125 *
02126 * @note No return value - output errors are silently discarded
02127 * @note Buffer is stack-allocated; safe for re-entrant calls on different tasks
02128 * @warning Only available when RX_IS_SIMULATOR is 0 (hardware builds)
02129 *
02130 * @par Thread Safety:
02131 * Not safe for concurrent access on SCI9 without external mutex.
02132 *
02133 * @par Performance:
02134 * - Execution time: ~90 us per digit @ 115200 baud + digit-loop overhead
02135 * - Stack usage: 32 bytes (buffer + locals)
02136 *
02137 * @par Example:
02138 * @code{.c}
02139 * uart_debug_puts("Value: ");
02140 * uart_debug_putint(42); // Sends "42"
02141 * uart_debug_putint(-2147483648); // Sends "-2147483648"
02142 * uart_debug_putc('\n');
02143 * @endcode
02144 *
02145 * @see uart_debug_puthex() Print value in hexadecimal
02146 * @see uart_debug_puts() Underlying string transmit
02147 *
02148 * @since Version 1.0.0
02149 */

02181 }
02182
02183 /**
02184  * @brief Transmit 32-bit unsigned integer as hexadecimal string on debug UART
02185  *
02186  * @details
02187  * Transmits "0x" prefix followed by the specified number of uppercase hex
02188  * digits of `value` on SCI9. Digits are always printed most-significant first.
02189  * The `digits` parameter is clamped to [k_uart_hex_min_digits, k_uart_hex_max_digits]
02190  * (1-8) before use.
02191  *
02192  * **Algorithm steps:**
02193  * 1. Send "0x" prefix via uart_debug_puts()
02194  * 2. Clamp digits to [1, 8]
02195  * 3. Iterate nibbles from MSN to LSN (statically bounded by k_uart_hex_max_digits)
02196  * 4. For each nibble index < digits, extract nibble and print uppercase hex char
02197  *
02198  *
02199  *
02200  * @pre uart_debug_init() must have been called successfully
02201  * @pre uart_debug_puts() and uart_debug_putc() must be functional
02202  *
02203  * @post "0x" followed by `digits` uppercase hex characters transmitted on SCI9
02204  * @post digits clamped to [1, 8] if out of range
02205  *
02206  * @note Uses static lookup table s_hex[] for digit-to-character conversion
02207  * @note Always prefixes output with "0x"
02208  * @warning Only available when RX_IS_SIMULATOR is 0 (hardware builds)
02209  *
02210  * @par Thread Safety:
02211  * Not safe for concurrent access on SCI9 without external mutex.
02212  *
02213  * @par Performance:
02214  * - Execution time: ~90 us per character @ 115200 baud
02215  * - Stack usage: 24 bytes
02216  *
02217  * @par Example:
02218  * @code{.c}
02219  * uart_debug_puts("Addr: ");
02220  * uart_debug_puthex(0xDEADBEEF, 8); // Sends "0xDEADBEEF"
02221  * uart_debug_puthex(0x42, 2);      // Sends "0x42"
02222  * uart_debug_putc('\n');
02223  * @endcode
02224  *
02225  * @see uart_debug_putint() Print signed decimal value
02226  * @see uart_debug_puts() Underlying string transmit
02227  *
02228  * @since Version 1.0.0
